surrounding GBV are the types of messages that seem to engage the public the most. Our results could help inform and guide future GBV campaigns while also informing the NGOs of the lack of representation in their messages about GBV toward important vulnerable populations, such as adolescents and Indigenous groups. Nevertheless, further research related to hashtag feminism by Mexico-based NGOs on GBV, such as the demographics of X users who engage on these posts and the types of activism interactions among X users on other social media platforms, is vital to understand the population that NGOs reach and how the messages shared on these campaigns translate into activism online and offline.

Acknowledgments

The authors would like to thank Yxchel Tejeda and Julia Godinez for their support in the coding and analysis of the data for this project.

Abstract

Background: Social media is a vital tool for health organizations, enabling them to share evidence-based information, educate the public, correct misinformation, and support a more informed and healthier society.

Objective: This study aimed to categorize health organizations' content on social media into topics; examine public engagement, sentiment, and emotional responses to these topics; and identify gaps in fear between health organizations' messages and the public response.

Methods: Real data were collected from the official Instagram accounts of health organizations worldwide. The BERTopic algorithm for topic modeling was used to categorize health organizations' posts into distinct topics. For each identified topic, we analyzed the engagement metrics (number of comments and likes) of posts categorized under the same topic, calculating the average engagement received. We examined the sentiment and emotional content of both posts and responses within the same topic, providing insights into the distributions of sentiment and emotions for each topic. Special attention was given to identifying emotions, such as fear, expressed in the posts and responses. In addition, a linguistic analysis and an analysis of sentiments and emotions over time were conducted.

Results: A total of 6082 posts and 82,982 comments were collected from the official Instagram accounts of 8 health organizations. The study revealed that topics related to COVID-19, vaccines, and humanitarian crises (such as the Ukraine conflict and the war in Gaza) generated the highest engagement. Our sentiment analysis of the responses to health organizations' posts showed that topics related to vaccines and monkeypox generated the highest percentage of negative responses. Fear was the dominant emotion expressed in the posts' text, while the public's responses showed more varied emotions, with anger notably high in discussions around vaccines. Gaps were observed between the level of fear conveyed in posts published by health organizations and in the fear conveyed in the public's responses to such posts, especially regarding mask wearing during COVID-19 and the influenza vaccine.

Conclusions: This study underscores the importance of transparent communication that considers the emotional and sentiment-driven responses of the public on social media, particularly regarding vaccines. Understanding the psychological and social dynamics associated with public interaction with health information online can help health organizations achieve public health goals, fostering trust, countering misinformation, and promoting informed health behavior.

Introduction

Background

Social networks are used by billions of people around the world, making them an effective platform for reaching a wide range of audiences. Health organizations, such as the World Health Organization (WHO), use social networks to disseminate important health-related information [1-5]; provide real-time updates, news, and emergency guidelines [6]; and promote awareness of diseases [7] and mental health [8]. Health organizations also promote vaccination compliance by disseminating information regarding vaccination importance, safety, and disease severity [9].

In contrast to the content published by social network users unaffiliated with health organizations, who can spread a large amount of inaccurate, false, and misleading information about health-related issues [10,11], the health-related content published on social networks by official health organizations enables the public to have access to reliable and useful information [12-14]. Therefore, health organizations are important actors in social media as reliable sources, providing evidence-based and authoritative information [15]. Through their efforts, these organizations educate the public, dispel myths, and help the community become healthier and more informed [16].

In addition to serving as a means of disseminating health-related information, social networks provide the public with the opportunity to participate in discussions and conversations with health organizations [17] by posting comments, sharing posts, and liking posts. Members of the public can also ask questions about the health issue being discussed, and the organizations that disseminate the information can respond. Active public participation can enhance individuals' understanding of health-related content [18,19] and can foster public trust in and appreciation for science [20]. In addition, health organizations are able to pinpoint concerns related to specific health topics, gain insight into public opinion [17-25], and identify topics that result in misinformation [26].

However, health-related messages disseminated by health organizations can provoke negative public reactions [27]. When combined with contradictory messages from unaffiliated social media users, this can lead to undesired health behaviors, such as vaccine hesitancy, noncompliance with health directives, and diminished trust in the reliability of health organizations [28-30].

Understanding public emotions in response to information disseminated by health organizations on social media is important for assessing the effectiveness of health communication strategies [31]. Sentiment and emotion analysis are widely used for determining sentiment polarity and detecting specific emotions expressed in textual data [32]. Sentiment analysis categorizes a text as positive, negative, or neutral, while emotion analysis identifies specific emotions expressed within a text [32]. Fundamental emotions, such as happiness, sadness, anger, disgust, surprise, and fear, can be detected, along with more nuanced emotions such as confusion and trust [33,34]. Among these emotions, fear is an important factor in health communication, as it can influence public perception, engagement, and behavioral responses [35].

Various theoretical models, such as the extended parallel process model [36], have explored how fear is used in public health messaging to encourage protective behaviors. This model suggests that individuals respond to fear-based messages depending on their perceived threat level and their sense of efficacy in managing the threat. According to this model, when perceived risk is high and the message also offers a clear solution, individuals are more likely to engage positively and adopt protective behaviors. However, if either condition is not met, responses may be negative, leading to outcomes such as avoidance or denial [36]. Therefore, fear is a crucial factor to consider in public health communication.

Despite the need to examine how the public emotionally responds to information shared by health organizations on social media, studies examining the topics communicated by these organizations and the corresponding responses from the public are sparse. The aim of this study is to analyze and characterize the content disseminated by health organizations on social media into topics, as well as social media users' responses to this content and the engagement, sentiment, and emotions induced by this content. In addition, we aim to identify gaps in fear between health organizations' messages and public responses.

Related Work

In this section, we provide an overview of various studies associated with health-related content and the topic modeling and sentiment analysis of such content.

Sentiment Analysis of Health-Related Social Media Content

Many studies examined the sentiment and public opinion surrounding the COVID-19 vaccine on Twitter [21,23,24,37-53]. For example, an analysis of Twitter data was conducted by Niu et al [24] to examine public opinion and sentiment before and during the administration of the COVID-19 vaccines in Japan. They found that negative sentiment toward the vaccines dominated positive sentiment in Japan, and concerns about side effects may have outweighed fears of infection at the beginning of the vaccination process.

Numerous studies leveraged machine learning techniques to classify tweets as positive, negative, or neutral sentiment toward vaccines, enabling the identification of vaccine hesitancy among communities and social media users [35,54-68]. Most of these studies collected data from Twitter using keywords or hashtags related to vaccinations. Chakraborty et al [56] used deep learning to analyze 226,668 COVID-19 tweets from December 2019 to May 2020, achieving 81% accuracy. Most tweets showed positive or neutral sentiment, while highly retweeted posts were predominantly neutral or negative.

XSL•FO
RenderX

Topic Modeling for Health-Related Social Media Content

Several studies have used topic modeling to examine health-related discussions on social media, focusing on topics such as blood donation [69], cancer-related content [70], and vaccine-related conversations [71]. Paul and Dredze [72] proposed the ailment topic aspect model to identify health topics on Twitter. Analyzing 144 million tweets, they identified 13 topics linked to seasonal influenza, allergies, temporal surveillance, and obesity-related geographic data in the United States.

Seltzer et al [73] analyzed 500 Instagram (Meta Platforms, Inc) images tagged #zika from May to August 2016, analyzing them by sentiment, content, and engagement. A total of 299 images were related to health, while 193 focused on topics of public interest. Sentiments and emotion analysis revealed that fear and negative emotions were linked to Zika transmission and response uncertainty. The study highlighted Instagram's value in understanding public sentiment and addressing gaps in health communication. Furthermore, Muralidhara and Paul [74] analyzed 96,426 Instagram posts collected between September and October 2016, using 269 health-related hashtags. Polylingual topic modeling approach was used to identify 47 health-related topics spanning 10 broad categories: acute illness, alternative medicine, chronic illness and pain, diet, exercise, health care and medicine, mental health, musculoskeletal health and dermatology, sleep, and substance abuse. Kim et al [75] analyzed 96,302 Instagram photos and 513,694 comments with antivaccination hashtags, focusing on photo features, engagement, and sentiment. Most photos (52.24%) were categorized as "text." "Food" and "plant" photos received the most positive comments, while "text" photos, despite high engagement, received fewer positive responses.

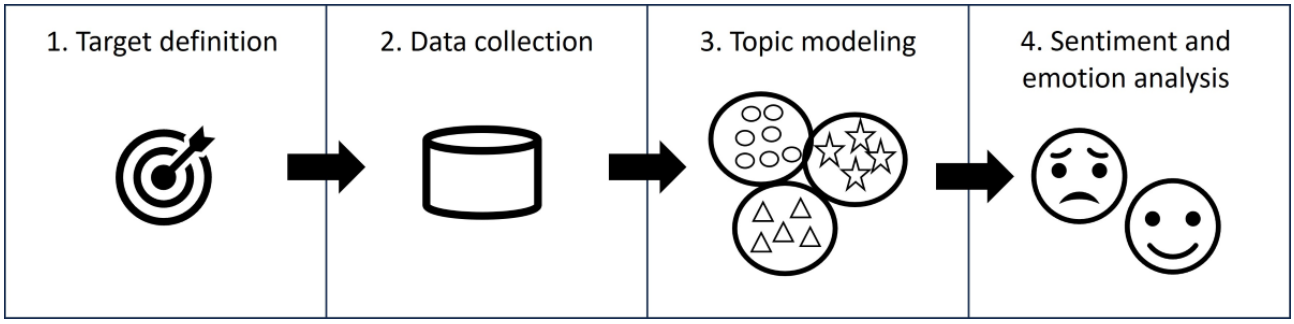
Other studies focused on dividing vaccine content on social networks into topics [40,41,43,45,52,53,76]. The study by Kwok et al [76] examined tweets of Australian users regarding COVID-19 vaccination on Twitter. Using a latent Dirichlet allocation topic model, they identified 3 commonly discussed topics: attitudes toward COVID-19 and vaccination, advocacy for infection control measures against COVID-19, and misconceptions and complaints regarding COVID-19. Similarly, Lyu et al [40] used latent Dirichlet allocation to analyze COVID-19 vaccine discussions on Twitter, identifying 16 topics grouped into 5 themes. Vaccination opinions were the most discussed topic. Emotion analysis showed trust as the dominant emotion, followed by anticipation, fear, and sadness. In addition, Chandrasekaran et al [43] used the correlation explanation topic modeling algorithm to examine COVID-19 vaccine–related tweets. The authors identified 16 topics in the COVID-19 vaccination tweets, which were grouped into 6 broader themes. Most tweets regarding COVID-19 vaccination centered on vaccine policy, vaccine hesitancy, and postvaccination symptoms and side effects.

Analysis of Health Care Providers' Content and Public Responses on Social Media

Several studies have examined content published on social networks by health care providers. Among them, Kim and Kim [77] analyzed 1545 Instagram photos published by the US Centers for Disease Control and Prevention (CDC) and public comments using Microsoft Azure Cognitive Services. Their findings showed that most images featured text or people, but those with larger faces or flashy elements tended to receive less engagement. Happiness and neutral emotions in comments were negatively correlated with interaction levels. Pinto et al [78] analyzed 632 Instagram posts from Portugal's National Health Service (NHS) and Brazil's Ministry of Health (MH) in 2019, mapping 53 topics for the NHS and 63 for the MH. The NHS emphasized healthy eating and blood donation, while the MH focused on vaccination campaigns, dengue prevention, and HIV awareness.

Mello et al [79] analyzed 726 Instagram posts from the WHO and CDC in 2020 to explore how these organizations communicated COVID-19 risks. Their study focused on messaging related to threat and efficacy, cues to action, and indicators of credibility. According to the findings, efficacy messages, such as those promoting preventive behaviors, were more prevalent, while threat messages addressing the susceptibility and severity of COVID-19 were less common. The study concluded that improving credibility cues, using compelling visuals, tailoring content for diverse audiences, and leveraging Instagram's interactive features could enhance public health communication, boosting engagement, trust, and impact.

Vaghefi et al [80] analyzed health care providers' messages on Twitter from May 2018 to May 2019 using machine learning, including Bidirectional Encoder Representations from Transformers (BERT)–based models, to classify tweets as professional communications or health-related information, further categorizing them as fear based or hope based. Results showed that fear-based messages were widely shared by the public but were less effective at motivating constructive health actions, while hope-based messages resonated more with health care providers. While this study [80] examined health care providers' content and the fear evoked by their messages on Twitter, our study focuses on categorizing health care providers' posts into distinct topics; analyzing engagement metrics, sentiment, and emotional content within each topic; and identifying the gaps between the fear expressed in messages from health organizations and the fear observed in public responses to such content. In contrast, Vaghefi et al [80] did not analyze the public comments to measure fear in relation to health care providers' messages; instead, they focused on public interactions, such as retweets and replies, to study information propagation.



Methods

Overview

This section outlines the proposed methodology, which consists of four main phases, as illustrated in Figure 1: (1) defining the targeted health organizations, (2) gathering data from the selected health organization accounts, (3) performing topic modeling on health organization content, and (4) analyzing the sentiment and emotion associated with each topic and the public's response to it.

XSL•FO
RenderX

Figure 1. An overview of the methodology's main phases.

Detailed descriptions of each phase are provided in the subsections that follow.

Target Definition

The first phase of our methodology was to define the group of health organizations to be examined. These organizations were selected based on their status as official government entities or government-supported health agencies responsible for public health policies, research, and regulations, ensuring that the study focused on authoritative sources [81-88]. In addition, a minimum threshold of 10,000 followers was set for health organization accounts to ensure sufficient activity and public engagement.

A brief description of each organization is provided in Textbox 1.

Textbox 1. Description of the health organizations included in this study.

Description
1. The World Health Organization (WHO): the WHO is the United Nations agency tasked with connecting nations around the world to promote health, keep the world safe, and serve populations considered vulnerable [81]. The organization's official Instagram account is named WHO.
2. Department of Health and Human Services (HHS): the HHS aims to enhance the health and well-being of the residents or citizens of the United States by providing effective health and human services and fostering sound, sustained advances in the sciences underlying medicine, public health, and social services [82]. HHSgov is the official Instagram account of the HHS.
3. The Office of Minority Health (OMH): the OMH is part of the HHS dedicated to improving the health of racial and ethnic minority groups. The OMH fulfills its commitment to improving the health of racial and ethnic minority groups in large part by developing health policies and programs that help eliminate health disparities [83]. MINORITYHEALTH is the official Instagram account of the OMH.
4. National Institutes of Health (NIH): the NIH is the leading federal agency in the United States responsible for conducting and supporting medical research. The NIH, which is part of the HHS, is one of the world's most prominent centers for medical research. Its mission is to enhance human health by advancing research across a wide range of scientific disciplines [84]. The organization's official Instagram account is named NIHgov.
5. The National Institute of Mental Health (NIMH): the NIMH is the US agency responsible for research on mental health. Its primary objective is to understand, treat, and prevent mental illness by conducting basic and clinical research. The NIMH is one of the 27 institutes and centers that comprise the NIH, which is part of the HHS [85]. NIMHgov is the official Instagram account of the NIMH.
6. The US Centers for Disease Control and Prevention (CDC): the CDC is a science-based, data-driven organization that leads the United States' efforts to protect the public's health. The CDC is one of the major components of the HHS, and it aims to protect the residents of the United States from health, safety, and security threats, both foreign and domestic [86]. CDCgov is the official Instagram account of the CDC.
7. The UK National Health Service (NHS): the NHS was established as the public health care system of the United Kingdom. It is one of the largest and most comprehensive health care systems in the world. The NHS provides various types of services, including mental health services, general practitioners, hospitals, and treatment facilities. The NHS is dedicated to improving the overall health of the population by promoting public health initiatives, health education, vaccination programs, and disease prevention campaigns [87]. The organization's official Instagram account is named NHS.
8. The US Food and Drug Administration (FDA): the FDA is a governmental regulatory agency responsible for protecting public health by ensuring the safety, efficacy, and security of human and veterinary drugs, biological products, and medical devices [88]. The organization's official Instagram account is named FDA.

It is important to note that, because we selected health organizations with a high number of followers, the resulting sample skewed toward US-based organizations. Most accounts originated from the United States, with 1 from the United Kingdom and 1 global organization (WHO). This concentration may affect the generalizability of the findings, as both the published content and the public responses are likely influenced by US-specific health priorities and cultural context.

Data Collection

We chose Instagram as the social media platform for its visual and interactive nature, which allows health organizations to share information and engage with the public effectively [89]. We searched for the official Instagram accounts of health care organizations using Instagram's search box. Table 1 provides the name of each official Instagram account for the organizations, along with the total number of posts published since the account's creation and the number of followers, as recorded in August 2024. As can be seen in Table 1, the CDC,

XSL•FO
RenderX

WHO, and Office of Minority Health are the organizations that publish the most posts. The WHO's account has the largest number of followers.

To collect the health organizations' Instagram posts, we connected with the Instagram application programming interface (API) using the RapidAPI website. This website is a large API hub that allows to connect with tens of thousands of public Representational State Transfer APIs over the internet.

The posts were collected between April 7, 2017, and November 17, 2023. Each Instagram post included the publication date, the number of likes, the number of comments, text, and a photo. For each post, we collected the comments, including the publication date, the comment text, and the number of likes. A total of 6082 posts and 82,982 comments were collected using the Instagram API. All retrieved posts and comments were included in the analysis. Table 2 presents the relevant statistics for the collected posts and comments for each health organization's Instagram account. We analyzed all the posts that the API allowed us to retrieve, without applying selection criteria or filtering specific posts. Comments were collected only from the original posts, excluding replies to comments.

Table 1. Statistics for the health organizations' Instagram accounts, ranked by number of followers (highest to lowest).

Organization name	Instagram account name	Published posts, n	Followers, n
Centers for Disease Control	CDCGOV	6359	2.5 million
World Health Organization	WHO	3893	12 million
National Health Service	NHS	695	564,000
Department of Health and Human Services	HHSGOV	3269	202,000
Food and Drug Administration	FDA	801	122,000
National Institute of Mental Health	NIMHGOV	674	64,100
National Institutes of Health	NIHGOV	1867	279,000
Office of Minority Health	MINORITYHEALTH	3909	15,400

Table 2. Statistics for the collected posts and comments of each health organization's Instagram account.

Name of health organization	Collected posts, n	Collected comments, n	Number of likes, mean (SD)
Centers for Disease Control	4298	58,471	2725.341 (3870.086)
World Health Organization	527	15,448	18349.774 (28197.828)
National Health Service	277	3826	1443.018 (1386.701)
Department of Health and Human Services	116	896	207.836 (270.549)
Food and Drug Administration	85	565	203.259 (183.758)
National Institute of Mental Health	301	1096	185.920 (142.871)
National Institutes of Health	253	1987	723.447 (709.083)
Office of Minority Health	225	603	34.124 (31.448)

Ethical Considerations

The data collection process and analysis were approved by the Emek Yezreel College Ethical Review Board (2023-81 YVC EMEK).

As the research relied solely on publicly available social media data and did not involve direct interaction with individuals, informed consent was not applicable. No compensation was offered or provided, as the study did not involve direct participation of human participants.

No identifiable private user information was collected or analyzed. All data used in the analysis were publicly available and did not contain personally identifiable information.

Topic Modeling

Text from the posts published by health organization accounts was analyzed using BERTopic [90]. Note that we removed the names of the health organizations and their abbreviations from the text to avoid creating topics around each organization. Stop words were also removed from the text.

We used the C_V coherence score to evaluate the quality and interpretability of the topics produced by the model. This measure combines the indirect cosine measure with normalized pointwise mutual information and a Boolean sliding window [91]. The coherence score indicates how closely related and coherent the words are in a topic. Using the average coherence metric, which is the average of the coherence metrics within each topic, we measured the model's ability to generate coherent and meaningful topics. This score enabled us to evaluate the overall effectiveness of the model in producing topics with a high degree of semantic similarity.

We performed 6 steps in BERTopic to analyze the posts (Textbox 2).

XSL•FO
RenderX

Textbox 2. Six-step BERTopic analysis of posts.

1. Embedding tweets: in this step, the text in the posts was converted into numerical representations using a sentence-transformers model named All-MiniLM-L6-v2 [92].
2. Dimensionality reduction: uniform manifold approximation and projection [93] was used to reduce the dimensionality of the embedded text, with the following parameters: _neighbors=15, n_components=3, min_dist=0, and metric = 'cosine.'
3. Cluster tweets: the text was grouped into clusters using the hierarchical density-based spatial clustering of applications with noise density-based clustering technique [94], with the following parameters: min_cluster_size=40, metric="Euclidean," and cluster_selection_method='eom.'
4. Word frequency analysis in clusters: the frequency of each word in each cluster was determined at the cluster level.
5. Topic representation: to represent the topics in the Instagram posts and responses, term frequency–inverse document frequency (TF-IDF) was adapted to work on a cluster or topic level instead of a tweet level. A new TF-IDF representation was used called class-based TF-IDF (c-TF-IDF).
6. Outlier reduction: hierarchical density-based spatial clustering of applications with noise identified texts that were outliers, meaning they did not belong to any of the established topics. To address this, we calculated the c-TF-IDF representation for each outlier text and compared its cosine similarity with the c-TF-IDF representations of the existing topics. By associating outlier texts with the closest matching topic based on similarity, we minimized the number of texts classified as outliers.

Sentiment and Emotion Analysis

Having categorized the health organizations' posts into topics, we analyzed the emotions and sentiment of each post and comment associated with a particular topic. Sentiment analysis was conducted using *distilbert - base - multilingual - cased - sentiments - student*, which achieved an average accuracy of 0.808 on the test set [95]. This is a distilled version of a zero-shot classification pipeline trained on the multilingual sentiment dataset. Zero-shot classification is a machine learning technique that allows models to classify data into categories they have never encountered during training without requiring labeled examples to be provided. It accomplishes this by leveraging contextual understanding and semantic relationships between seen and unseen classes, often using embeddings or natural language models [96]. In this case, a larger "teacher" model, *MoritzLaurer/mDeBERTa-v3-base-mnli-xnli*, was used to train a smaller "student" model, *distilbert-base-multilingual-cased*. Using this distillation process, the student model maintains high classification performance while being more efficient and lightweight. According to the training log, the student model achieved an impressive agreement rate of 88.29% with its teacher model.

Emotion analysis of 6 basic emotions (fear, anger, disgust, joy, sadness, and surprise) was conducted using a fine-tuned checkpoint of the DistilRoBERTa-base model called *j-hartmann/emotion-english-distilroberta-base*. The model was trained on 6 diverse datasets [97]. The model was trained on a balanced subset from several datasets of nearly 20,000 observations in total. In total, 80% of this balanced subset was used for training and 20% for evaluation. The evaluation accuracy was 66%.

To ensure the accuracy of the models in identifying sentiments and emotions, we randomly selected 100 posts and comments. We manually classified them based on their dominant sentiment and dominant emotion. The results showed that the sentiment model achieved 92% accuracy, while the emotion model demonstrated 84% accuracy. Considering sentiment models predict binary classification and emotion models face greater complexity due to emotions' multidimensional nature, the results are logical. Therefore, applying the models to the data was expected to provide sufficiently reliable outcomes.

Each post and posts' comments received a sentiment score of positive, negative, or neutral, as well as an emotion score of fear, anger, disgust, joy, sadness, or surprise.

For each topic, we calculated the following:

- Average number of comments (the average number of comments for all posts in the topic).
- Average number of likes (the average number of likes for all posts in the topic).
- Average post sentiment scores (the average positive, negative, and neutral sentiment scores for all posts in the topic).
- Average post emotion scores (the average fear, anger, disgust, joy, sadness, and surprise scores for all posts in the topic).
- Average comment sentiment scores (the average positive, negative, and neutral sentiment scores for all post comments in the topic).
- Average comment emotion scores (average fear, anger, disgust, joy, sadness, and surprise scores were calculated for all post comments in the topic).
- Gap (the difference between the average fear score of the posts and the average fear score of the comments).

Linguistic Analysis

The objective of this analysis was to identify the most significant phrases used by health organizations in posts that resonated more positively with the public (ie, associated with higher positive sentiment in comments) compared to those that elicited more negative reactions (higher negative sentiment in comments).

For this purpose, we calculated the average sentiment score (positive and negative) of all comments related to each post. Posts were then categorized based on the dominant sentiment (positive or negative) derived from these average sentiment scores in comments, resulting in 2 groups: posts with predominantly positive comments and posts with predominantly negative comments.

XSL•FO
RenderX

For each group of posts, we extracted the top 50 most significant phrases, including single words (unigrams), 2-word phrases (bigrams), 3-word phrases (trigrams), and 4-word phrases (four-grams). The preprocessing involved removing hashtags from the text, eliminating stopwords, and calculating term importance using TF-IDF. TF-IDF estimates the significance of terms within a group of posts based on their frequency within each post as compared to the frequency across all posts in the group. The cumulative TF-IDF scores for each term were calculated by summing across all posts in the group, enabling the identification of the most significant phrases for each group of posts.

Time Analysis

In the time analysis section, we examined the average positive and negative sentiment in both comments and posts over the years. In addition, we analyzed the average levels of various emotions, including fear and anger, expressed in both posts and comments throughout the data collection period. Furthermore, we decided to calculate additional emotions of trust, disappointment, and confusion. The purpose of including these emotions was to extend the analysis beyond the 6 basic emotions, providing a broader range of emotional insights.

To calculate trust, we used the *ayoubkirouane/BERT-Emotions-Classifier* model [98], a fine-tuned BERT-based model designed for multilabel emotion classification. This model was trained on the sem_eval_2018_task_1 dataset. This model includes a wide range of emotions, such as anger, anticipation, disgust, fear, joy, love, optimism, pessimism, sadness, surprise, and trust.

For confusion and disappointment emotions, we used the *SamLowe/roberta-base-go_emotions* model [99], which is trained on the go_emotions dataset for multilabel classification. The go_emotions dataset, based on Reddit (Reddit, Inc) data, contains 28 emotion labels. The model achieved high performance in identifying confusion (with an accuracy of 0.972) and disappointment (with an accuracy of 0.974).

As part of the temporal analysis, we incorporated weekly COVID-19 mortality data in the United States using a publicly available dataset published by the National Center for Health Statistics [100]. The analysis included calculating a "COVID-19 death ratio," which represents the proportion of US COVID-19–related deaths to the total number of US deaths. We applied a rolling average smoothing technique across a 10-week window to reduce noise and variability in the data, allowing us to identify patterns over time. This approach allowed us to combine the mortality data alongside our sentiment and emotional analyses, providing valuable insights into the alignment between public responses and real-world outcomes.

Results

Topic Modeling

Using BERTopic, 36 topics were identified for the posts of the 8 health organization Instagram accounts. The average coherence score was 0.7374. A health expert reviewed the list of topics and suggested that we combine related topics.

Therefore, the following topics were combined: 7 topics related to COVID-19 were grouped together, 2 topics related to vaccines for children were grouped together, 2 topics related to monkeypox were grouped together, and 2 topics related to booster vaccines were combined. Combining the topics resulted in 25 topics, with an average coherence score of 0.7298. The health expert assigned a representative name to each topic. The topic names were assigned by analyzing the 10 most significant words for each topic, as determined by the c-TF-IDF scores (refer to the Methods section for more information about c-TF-IDF) from the BERTopic algorithm and cross-referencing them with example posts related to that topic. Each topic was automatically assigned a unique number starting from 0, following the default numbering convention used by the BERTopic algorithm. Table 3 lists the topics, indicating their number, name, and number of posts. Refer to Multimedia Appendix 1 for the 5 words with the highest c-TF-IDF for each topic.

XSL•FO
RenderX

Table 3. The number, name, and size of each topic.

Topic number	Topic name	Topic size, n
0	COVID-19	1446
1	Mental health	752
2	Children and vaccines	496
3	COVID-19 booster vaccine	288
4	Pregnant	246
5	Foodborne	235
6	Research	226
7	Community health	223

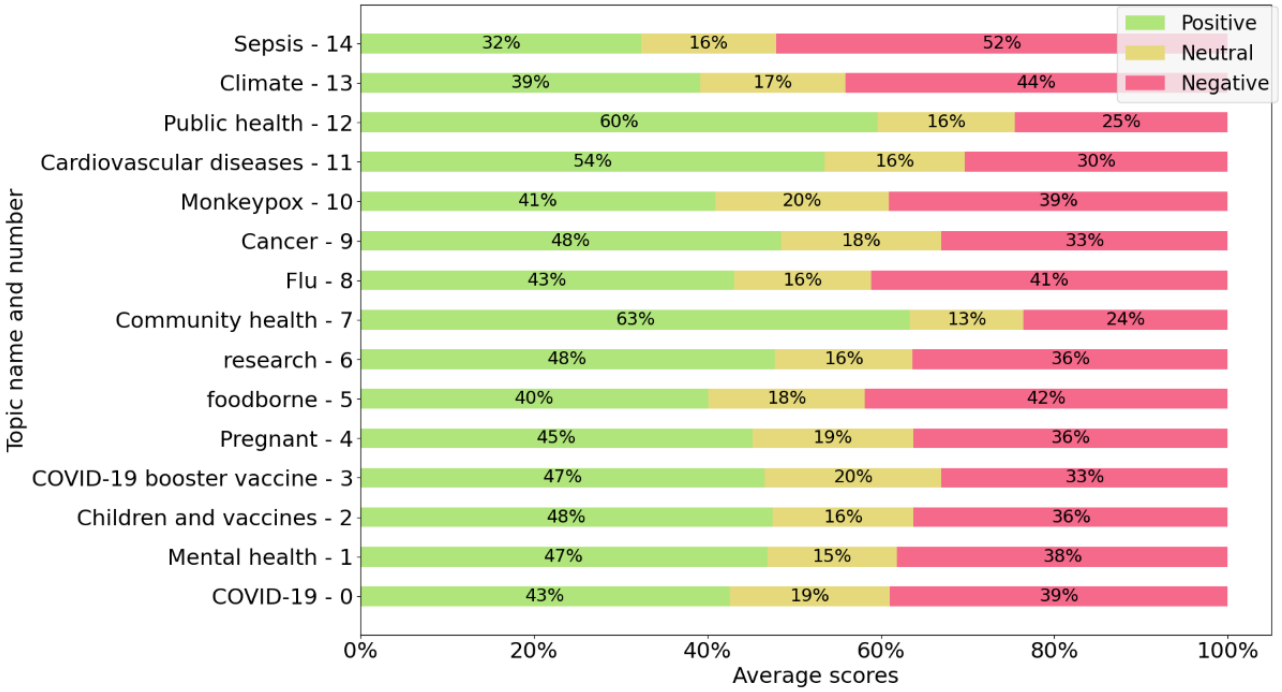
[a]RSV: respiratory syncytial virus.

Engagement Analysis

Our dataset includes engagement metrics for each post, specifically the number of likes and user comments.

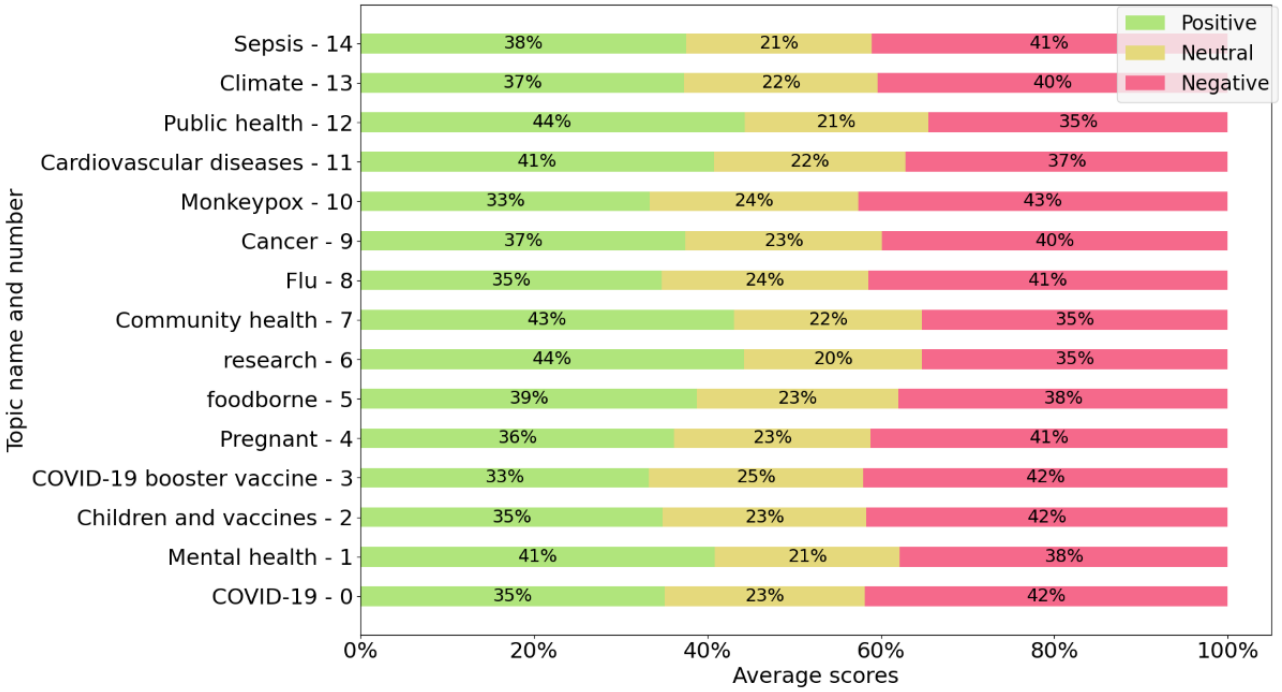
We calculated the average number of comments and likes for all posts in each topic. Multimedia Appendix 2 presents the average number of comments received per topic, while Multimedia Appendix 3 displays the average number of likes. Among the topics, those with the highest user engagement based on the average number of post comments were humanitarian issues, masks, and COVID-19. In terms of engagement measured by the average number of post likes, the leading topics were humanitarian issues, masks, and cancer. Multimedia Appendices 2 and 3 also show increased engagement for topics related to vaccines and COVID-19.



Sentiment Analysis

We analyzed the sentiment in the text of the posts and comments and calculated the sentiment scores of the posts and comments, as described in the Methods section.

Figures 2 and 3 present the average sentiment scores for health organizations' posts and comments, respectively. In Figures 2 and 3, we selected only the 15 largest topics (those containing the greatest number of posts). Figure 2 shows that in certain topics, such as sepsis, climate, and foodborne illnesses, negative sentiment is the most prominent in the health organizations' posts. However, in Figure 3, which presents the scores for the comments to the health organizations' posts, we see that there are more topics where negative sentiment is dominant than in Figure 2, with the greatest negative sentiment found in the comments for posts about vaccines, specifically for posts in the COVID-19, children and vaccines, booster vaccines, and monkeypox topics.



XSL•FO
RenderX

Figure 2. Sentiment scores of posts (average positive, neutral, and negative) for each topic.

While certain topics showed a dominant positive sentiment in the posts published by health organizations (as illustrated in Figure 2), this does not necessarily reflect how the public responds to those posts. The dominance of positive sentiment in these topics was based on the average sentiment scores, where the positive score was higher than both the negative and neutral scores. This indicated that these subjects were presented mostly positively by the organizations. However, when examining the sentiment expressed in user comments (Figure 3), we observed a contrasting response. In topics such as COVID-19, children and vaccines, and the COVID-19 booster vaccine, the comments exhibited predominantly negative sentiment, even though the organizations framed these topics positively. In these cases, the average negative score in the comments was higher than both the positive and neutral scores. In other words, while the organizations tried to communicate these topics in a positive light, the public's reaction to them was largely negative.

Figure 3. Sentiment scores of comments (average positive, neutral, and negative) for each topic.

XSL•FO
RenderX

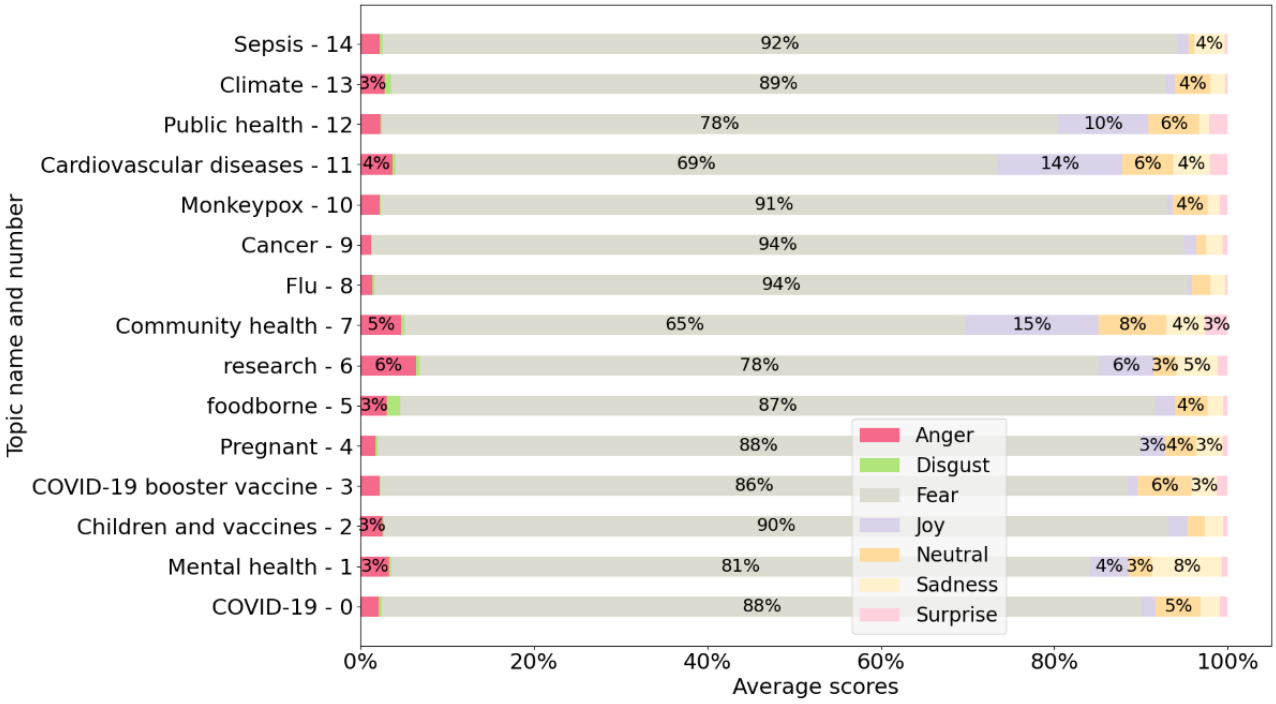
Emotion Analysis

We analyzed the emotion in the text of the posts and comments and calculated the emotion scores of the posts and comments, as described in the Methods section.

The emotions present were anger, disgust, fear, joy, neutral, sadness, and surprise. Figure 4 presents the average emotion scores for the posts, and Figure 5 displays the average emotion scores for the comments. In Figures 4 and 5, we selected only the 15 largest topics (those containing the greatest number of posts).

As seen in Figure 4, the dominant emotion in all topics was fear, and its scores were higher than those of all the other emotions in the posts. In other words, the text in the health organization posts was characterized by a very high level of fear. Among the topics with the highest fear emotion were sepsis, monkeypox, cancer, and flu.

Figure 4. Emotion scores of posts (average anger, disgust, fear, joy, neutral, sadness, and surprise) for each topic.



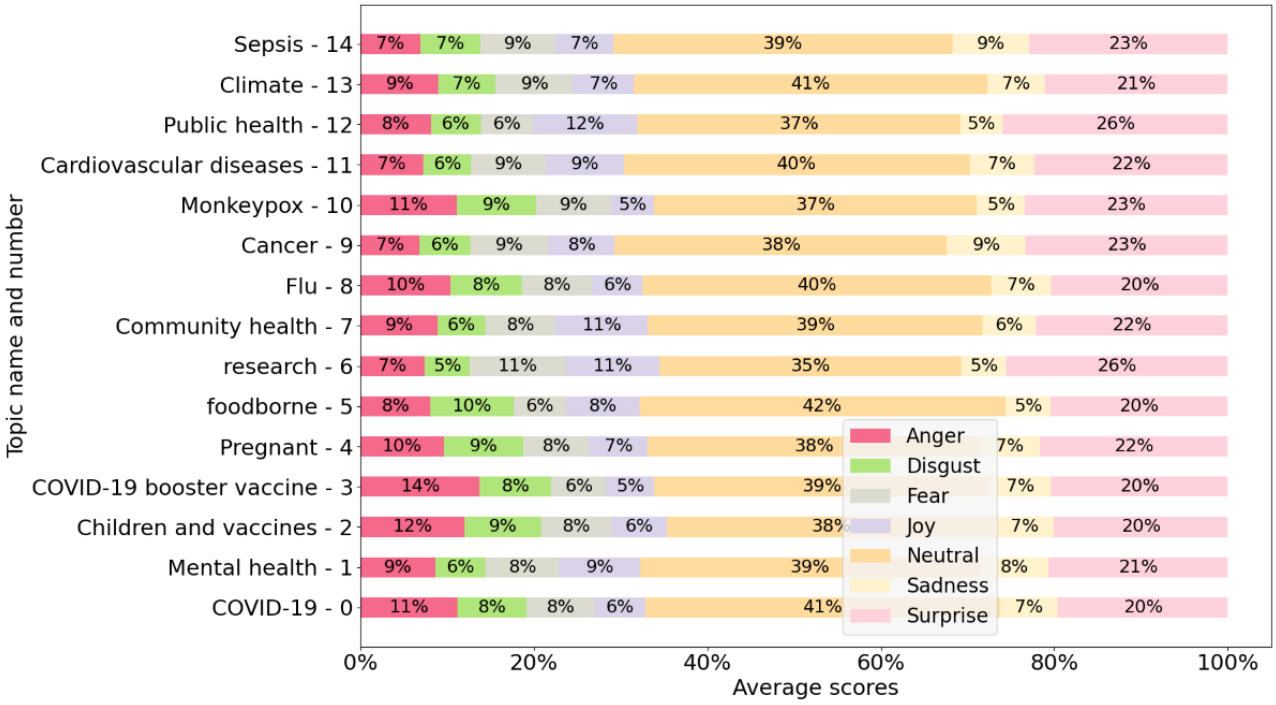


Figure 5. Emotion scores of comments (average anger, disgust, fear, joy, neutral, sadness, and surprise) for each topic.

XSL•FO
RenderX

However, as shown in Figure 5, fear is not the dominant emotion; instead, neutral responses prevail. This suggests a disconnect between what health organizations consider fear-inducing issues and how the public actually responds, displaying less fear. When examining other emotions in Figure 5, we see that the topic generating the most anger is vaccines, with the COVID-19 booster vaccine specifically eliciting the highest levels of anger. In terms of sadness, cancer and sepsis were the topics that evoked the strongest feelings of sadness.

Gap Analysis

Given the difference observed between the high average fear in the health organizations' posts compared to the very low fear in the public's responses to the posts, we examined the topics with the largest gap between the 2 average fears as revealed in the emotion analysis. For each topic, Table 4 presents the average fear in the posts of health organizations, the average fear in the comments, and the difference between the two. As can be seen in Table 4, the topics with the highest gap are masks and flu.

Table 4. Each topic's average scores for fear in post and comments and the gap.

Topic name	Topic number	Fear in posts, mean (SD)	Fear in comments, mean (SD)	Gap
Masks	15	0.958 (0.072)	0.092 (0.166)	0.881
Flu	8	0.938 (0.156)	0.066 (0.180)	0.857
Vector	16	0.931 (0.090)	0.101 (0.196)	0.846

[a]RSV: respiratory syncytial virus.

Linguistic Analysis

The linguistic analysis results are presented in Multimedia Appendix 4. It contains the top 50 phrases for unigrams, bigrams, trigrams, and four-grams in posts receiving predominantly positive or negative responses, along with their TF-IDF scores.

Results revealed that phrases associated with positive public responses promote public health awareness, vaccination benefits, and preventive measures. As an example, the phrases that were only included in the top 50 phrases of the health organizations' posts that received positive responses included "stay healthy" "awareness month," "signs symptoms," "raise awareness," "save lives," "help slow spread," "health care provider," and "better health better understanding." In contrast, phrases associated with negative sentiment related to vaccination efforts, outcomes, policy mandates, and health monitoring include terms such as "data tracker," "vaccinated covid," "dose vaccine," "severe

XSL•FO
RenderX

illness hospitalization," "illness hospitalization death," and "covid 19 vaccine booster."

Time Analysis

Figures 6-8 illustrate sentiment and emotional shifts in posts and comments from 2018 to 2023 along with the COVID-19 death ratio. The numbers 1 to 5 in Figures 6-8 represent 5 significant milestones during the COVID-19 pandemic. These include the following: (1) first report of COVID-19 in late 2019, (2) the declaration of COVID-19 as a global pandemic by the WHO in March 2020, (3) the administration of the first COVID-19 vaccine in December 2020 in the United Kingdom, (4) the peak of the Omicron wave in early 2022, and (5) the WHO's declaration in May 2023 that COVID-19 was no longer a global health emergency.

Figure 6. Evolution of sentiment (average positive and negative scores) in posts and comments over the years, combined with the COVID-19 death ratio.

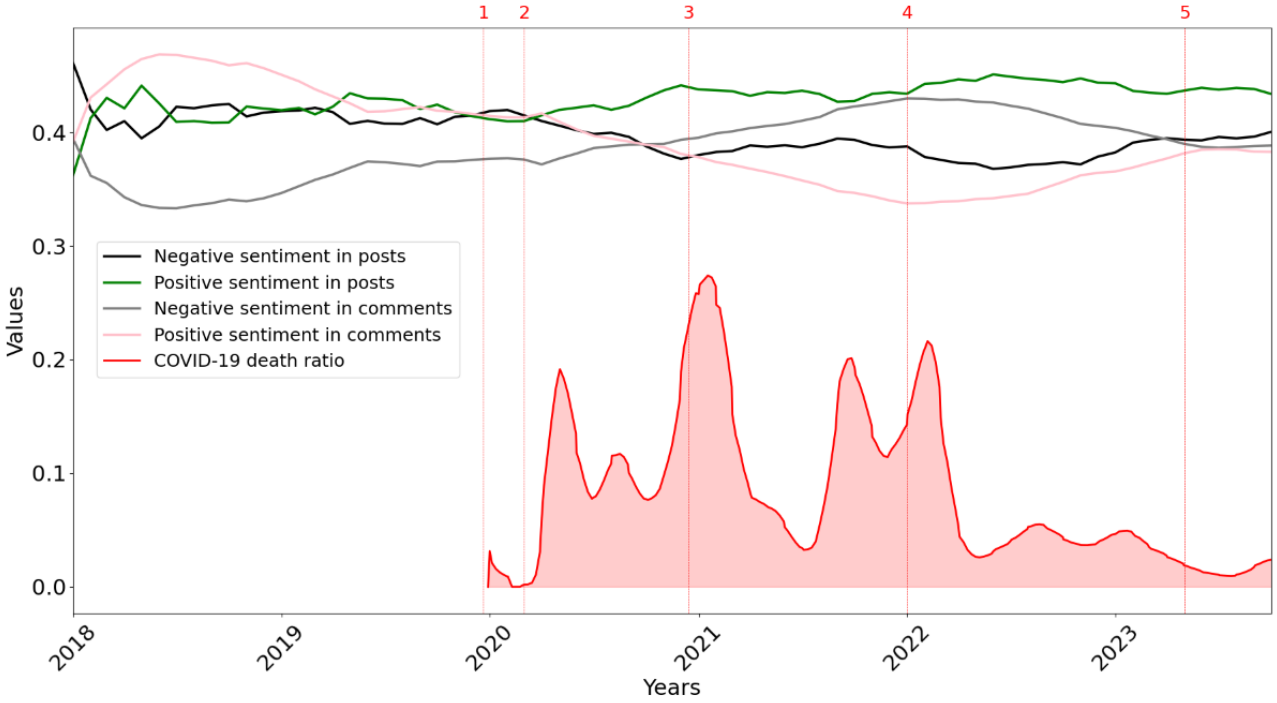

Figure 6 presents the average positive and negative sentiment expressed in posts and comments over time. The negative sentiment in comments increased over time and then began to decrease after the peak of the Omicron wave. Positive sentiment in comments showed a similar but opposite pattern, as it decreased and then increased after the peak of the Omicron wave. Regarding the sentiment of posts, it appeared that positivity in posts increased slightly over the years, while negativity decreased. The peaks of the COVID-19 death ratio aligned with increased negative sentiment in comments.

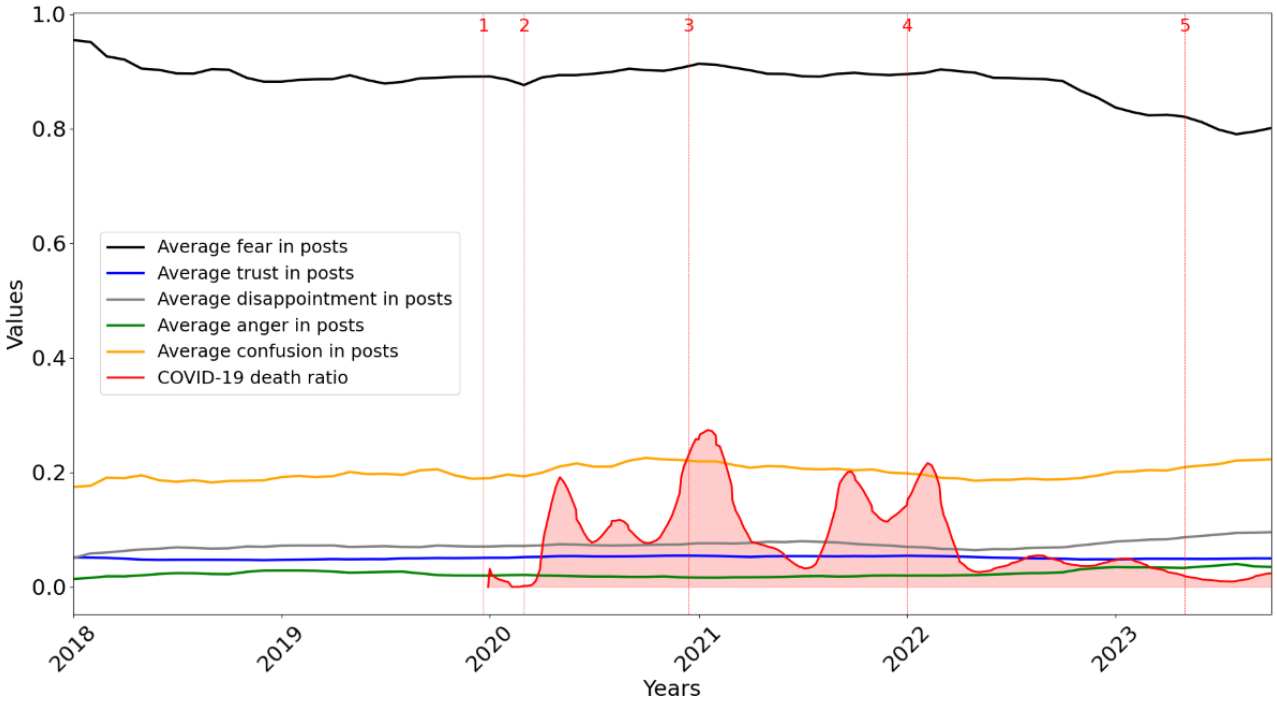
Figure 7 explores the average levels of emotions—fear, trust, disappointment, anger, and confusion—in posts. Fear consistently dominated posts and remained relatively steady until it declined, coinciding with a significant reduction in the death ratio. Trust, anger, and disappointment remained relatively steady throughout the years. Confusion gradually increased following the declaration of the pandemic.

XSL•FO
RenderX

Figure 7. Evolution of emotion (average scores for trust, fear, anger, confusion, and disappointment) in posts over the years, combined with the COVID-19 death ratio.



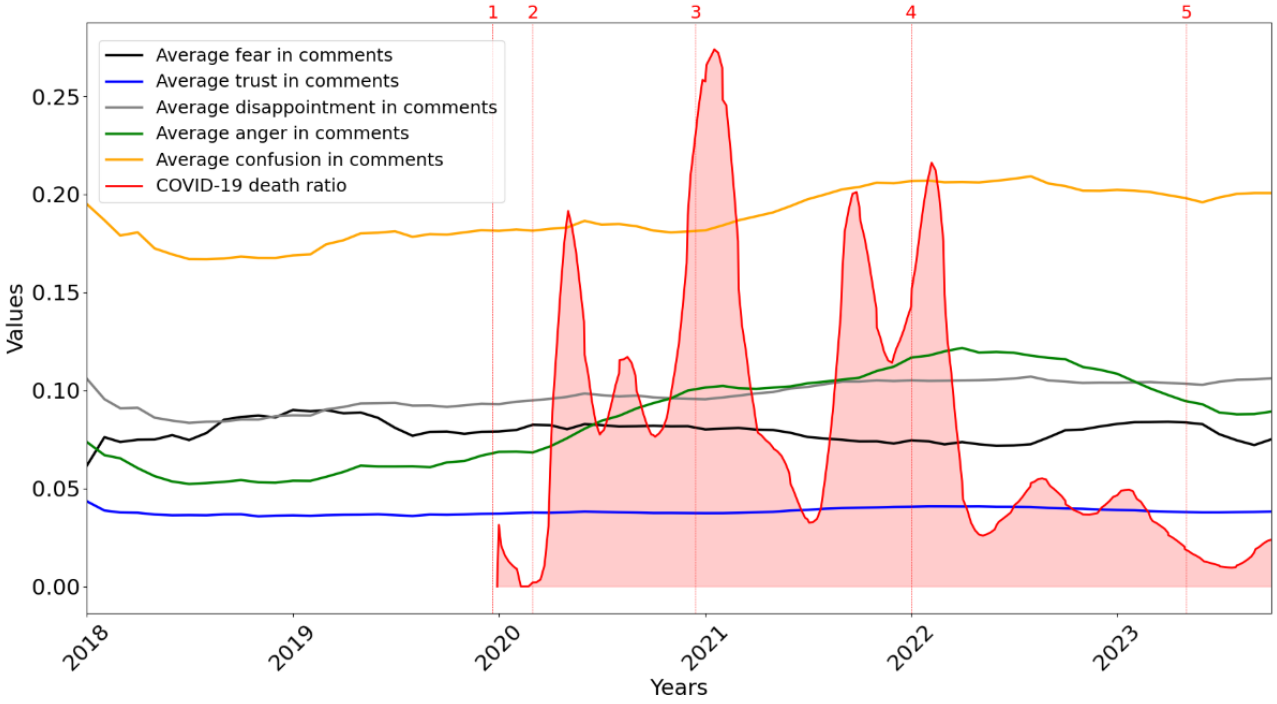


Figure 8 shows the average levels of emotions—fear, trust, disappointment, anger, and confusion—in comments over the same period. Emotions of fear and trust remained relatively steady throughout the years. Anger and disappointment increased around death ratio peaks and, overall, showed a general upward pattern over the years. However, anger began to decline slightly after the Omicron peak and the subsequent decrease in the death ratio.

Figure 8. Evolution of emotion (average scores for trust, fear, anger, confusion, and disappointment) in comments over the years, combined with the COVID-19 death ratio.

Discussion

Principal Findings

The findings of this study should be interpreted with consideration of the dataset's geographic composition. As most of the health organizations analyzed are based in the United States, the topics emphasized may reflect US-specific health priorities, and the patterns of public engagement, sentiment, and emotional responses to these topics may also be shaped by US cultural and social contexts. The selected health organizations have a high number of followers on the platform, hold substantial influence, and reach audiences beyond national boundaries. Still, the framing and intensity of reactions observed in this study may not be fully generalizable to health organizations in other countries or regions, particularly because the characteristics of the users engaging with the content (such as their geographic location or demographics) are unknown.

Our findings on engagement analysis show that humanitarian issues, including the Ukraine war and the war in Gaza, and the COVID-19 pandemic received the greatest response from the public. This supports prior research, which has shown that those disasters, including humanitarian crises, such as nature-related crises and wars, are a major concern of the public and policy makers [101]. In recent years, conflicts, such as the ongoing Ukraine war and the war in Gaza, have had a significant impact on international stability, affecting economies, migration patterns, and security measures, particularly in Europe [102]. These conflicts have not only disrupted local societies but have also prompted reevaluation of humanitarian aid and intervention strategies globally. The connection between humanitarian conflicts and adverse health outcomes is well documented. Studies have shown increased incidence of mental health disorders, infectious disease outbreaks, and chronic health conditions in conflict-affected areas [103]. As a result, health organizations worldwide have recognized the urgent need to develop comprehensive strategies for emergency preparedness. This includes enhancing public health response capabilities, improving prehospital care, and integrating disaster medicine in public health frameworks to better address humanitarian crises [104,105].

The COVID-19 pandemic has fundamentally altered global perceptions and practices across various sectors, revealing both strengths and weaknesses in systems and policies worldwide [106]. During the COVID-19 pandemic, the public turned to health organization websites and social media channels to receive timely updates on infection rates, government guidelines, and evolving safety protocols [107,108]. Trust in organizations such as the WHO and CDC was crucial, as these bodies communicated essential information, adapting advice as new data emerged about the virus's spread and impact. The results of this study further highlight that a significant portion of posts shared by health organizations focused on the topic of COVID-19. In addition, these posts generated substantial public engagement, demonstrating the public's heightened interest and concern regarding COVID-19–related information. Given the profound impact of COVID-19, the public remains extremely interested in these insights, recognizing that understanding what was done well and what failed can better prepare societies for future health crises. Consequently, the ongoing dialogue among scientists, policy makers, and the public about these findings continues to shape postpandemic recovery strategies and fortify global health preparedness [109].

Our sentiment and emotion analysis of responses to health organizations' posts showed that the highest percentage of negative scores was in topics related to vaccines and monkeypox. Moreover, our results show that the highest level of anger was observed in topics related to the COVID-19 booster and children's vaccination in general. The high anger and negative sentiment can be attributed to vaccine hesitancy.

Vaccine hesitancy and antivaccine movements have long posed significant challenges to public health [110], particularly in communities with historically low trust in government and pharmaceutical institutions [111]. The analysis of topics associated with high anger emotions, such as COVID-19 vaccines, can be enriched by examining the emotional characteristics and motivations of specific user groups with vaccine hesitancy. For instance, women are generally more likely to exhibit vaccine hesitancy than men [112]. Alternatively, older individuals tend to display lower levels of hesitancy, likely due to their awareness of their vulnerability to COVID-19 complications, which may alleviate their fear or anger [112]. Vaccine hesitancy is also more prevalent among individuals with lower economic security [112]. Trust also shapes emotional and cognitive characteristics. Higher trust in health care providers, scientists, and global health organizations such as the WHO correlates with reduced vaccine hesitancy [112]. Conversely, in some contexts, higher trust in religious leaders is linked to increased hesitancy [112].

The COVID-19 pandemic has increased skepticism toward routine immunizations and increased hesitancy even among those previously compliant with vaccination schedules. The rapid development of COVID-19 vaccines, coupled with widely publicized adverse effects, heightened fears and deepened mistrust [113]. In addition, misinformation and conflicting narratives on social media further fueled fear, anger, and uncertainty, particularly in communities already skeptical of public health authorities. Our findings reflect these trends, showing increases in public negativity, anger, and disappointment over time.

Our linguistic analysis highlights that messages emphasizing safety, prevention, and public health benefits tend to elicit positive sentiments, while messages emphasizing vaccination efforts, outcomes, policy mandates, and health monitoring tend to elicit negative sentiments. This underscores the need for health organizations to refine communication strategies, focusing on clear, trust-building messaging to address concerns and counteract negative sentiments effectively.

Our analysis also reveals a gap between the fear conveyed in posts by health organizations and the public's responses to these posts, particularly regarding the influenza vaccine and face masks during the COVID-19 pandemic. While health organizations intended to convey urgency, public comments did not reflect the same fear. Addressing skepticism and ambivalence about influenza vaccine and mask use is critical.

XSL•FO
RenderX

Face masks are a critical tool in pandemic response [114], and enhancing public understanding of their effectiveness is essential for improving adherence and compliance during future outbreaks.

The difference in fear responses between the influenza vaccine and face masks can be understood by examining the interplay of social, psychological, and cultural factors [114]. One factor is psychological reactance, which occurs when individuals perceive mandates, such as mask requirements, as threats to their autonomy. This perception, combined with beliefs that masks are ineffective and an aversion to being forced to wear them, can trigger anger and counterarguments. Individuals with strong psychological reactance are particularly likely to exhibit these responses, reinforcing and intensifying their antimask attitudes [115,116]. Such resistance is further exacerbated by personality traits, which not only strengthen antimask sentiments but also link to broader vaccine skepticism, exaggeration of COVID-19 risks, and resistance to social distancing, often influenced by political conservatism [117].

Social and cultural dynamics also shape mask perceptions. For example, in many Western societies, masks are seen as extraordinary artifacts associated with emergency, while in Asian cultures, they are normalized as part of daily life [118]. In collectivist cultures, mask wearing aligns with a sense of duty to protect the community [116]. In addition, stigma, appearance concerns, and fears of being perceived as overly cautious further hinder acceptance [119].

Policy decisions and public health campaigns significantly influence perceptions. During the COVID-19 pandemic, inconsistent messaging from health authorities and varying guidance on mask use between countries and organizations contributed to public confusion and skepticism regarding their efficacy [120], despite substantial scientific evidence supporting their role in reducing transmission rates [120,121]. Therefore, consistent messaging and targeted communication strategies should focus on populations with antimask perceptions, aiming to reduce stigmas and address the underlying factors driving these attitudes.

Historically, the influenza vaccine has engendered significant hesitancy and objection from segments of the general public, a trend particularly evident among health care workers, who are critical in promoting vaccination [122]. Factors contributing to this hesitancy include misconceptions about vaccine efficacy, fears of adverse effects, and a perceived lack of urgency surrounding influenza, particularly when compared to more severe illnesses such as COVID-19 [123,124]. The emergence of the COVID-19 pandemic exacerbated this situation. During the COVID-19 pandemic, public focus shifted intensely toward COVID-19 vaccination campaigns, leading to a diversion of attention and resources from influenza vaccination efforts [125]. The flood of information regarding COVID-19 vaccines overshadowed the long-standing influenza vaccine campaigns. As a result, many individuals prioritized the COVID-19 vaccine over the seasonal influenza vaccine [125]. Data indicating that compliance with the influenza vaccine plummeted in several countries during 2023 and 2024 compared to prepandemic years highlight the ongoing challenges faced by public health authorities [125].

Despite the availability of the influenza vaccine, social media misinformation and evolving health narratives regarding influenza and COVID-19 have led to an atmosphere of uncertainty. For instance, some individuals may mistakenly believe that if COVID-19 variants pose health risks, the influenza virus may be less significant or that acquiring one vaccine negates the need for others. This shift necessitates a reassessment of public health strategies to reengage communities with the importance of influenza vaccination. Health organizations must develop targeted messaging that addresses misconceptions, enhances understanding of the influenza virus's potential impact, and reinforces the protective benefits of vaccination, even during times when attention is focused on other diseases.

To summarize, in this study, we analyzed the quality of disseminated messages along 2 dimensions: public responses to topics and the emotions and sentiments expressed in those responses. Mapping these reactions to messages posted by health organizations is important for evaluating public engagement with specific health-related issues. Identifying emotional gaps can also help assess the effectiveness of health-related messages, revealing potential discrepancies between the importance health organizations assign to certain topics and the public's perceived importance.

Our findings highlight gaps in fear responses regarding the influenza vaccine and wearing face masks during the COVID-19 pandemic, underscoring the need for transparent communication from health authorities and comprehensive education campaigns to address misconceptions and reassure the public. Understanding the psychological and social factors driving vaccine hesitancy after the pandemic is essential for tailoring effective public health strategies. Efforts must focus on fostering trust through consistent and clear messaging, transparency about vaccine development processes, and open forums for addressing public concerns. By doing so, it will be possible to mitigate misinformation, reduce fear, enhance public compliance, and improve vaccine uptake across populations.

Limitations

Our study may have some limitations. We collected data from Instagram, and therefore, our results and conclusions are based on the posts and interactions on this social media platform. Our data did not include specific information about the users who commented on the health organizations' posts. However, according to general information about Instagram users by Statista [126], Instagram had 2 billion monthly active users in 2024, with India leading the platform's user base at approximately 360 million, followed by the United States with 169 million and Brazil with 134 million users. Younger users dominate the platform, with the 18- to 24-year age group being the largest demographic, followed by the 25- to 34-year age group. Participation declines significantly among older age groups, particularly those aged ≥55 years, who represent only a small fraction of the audience. Moreover, most users in the 18- to 34-year age group are men, while most users >34 years are women.

XSL•FO
RenderX

The absence of detailed user characteristics in our dataset may limit the generalizability of our findings, as biases could arise due to age, gender, educational level, or other demographic factors that influence engagement and sentiment patterns. Certain user groups may be overrepresented or underrepresented in the data, potentially shaping the interpretation of public responses. Future research should aim to systematically characterize respondents' profiles, leveraging available metadata or incorporating external surveys to gain a clearer understanding of the audience engaging with health-related content.

The study also has limitations regarding the influence of social media algorithms on post visibility and engagement. The social media algorithms prioritize content based on user interactions, interests, and platform-specific ranking mechanisms, potentially introducing bias in public sentiment patterns. Nevertheless, the decision as to whether to engage and how to respond is left to the users. Therefore, although engagement data may not fully represent the broader public, it still offers insights into those actively participating in discussions. To mitigate bias, we ensured a diverse dataset by including a substantial number of posts from multiple health organizations.

It is important to acknowledge that the models used in this study may have limitations. Although BERTopic is an effective topic modeling technique, it assumes that each document (in our case, each post) is associated with a single dominant topic, which does not always reflect reality. As posts can discuss a variety of interconnected topics, it is often difficult to classify them accurately under a single theme. Furthermore, topic separation relies on clustering techniques, which may not always produce clear or optimal topic divisions, resulting in the merging of distinct topics or the fragmentation of related discussions, reducing interpretability.

Similarly, the sentiment and emotion models may inherit biases from their training datasets, influencing detection. These models are not always fully accurate and often struggle to capture context-dependent sentiment shifts, irony, and implicit emotional expressions, which may result in misinterpretations.

In addition, as previously mentioned, the health organizations in this study are predominantly US based, with limited representation from other countries. This concentration may influence the topics represented in the dataset, reflecting US-specific health priorities and cultural dynamics, as well as the public sentiment, emotional responses, and engagement observed in relation to those topics. Future research could incorporate data from a more geographically diverse set of health organizations, enabling cross-cultural comparisons and providing a broader understanding of global public health communication and audience responses.

Conclusions

This study demonstrates the value of our methodology in assessing public responses and emotions expressed regarding health-related messages. By identifying emotional gaps, particularly fear, we were able to uncover discrepancies between the fear health organizations assign to issues and the fear that the public expresses in response. The greatest gaps were revealed with regard to influenza vaccines and face masks during COVID-19.

These findings emphasize the need for transparent communication and trust-building strategies that consider the emotional and sentiment-driven responses of the public on social media. By understanding the psychological and social dynamics of public interaction with health information, particularly regarding vaccine resistance, organizations can support public health goals, foster trust and efficient engagement, counter misinformation, and encourage informed health behaviors.

In future research, we plan to apply our topic modeling and sentiment and emotion analysis approach on other social media platforms to gain a more comprehensive view of the public's response to the posts of health organizations across various digital platforms. In addition, we aim to extend our analysis beyond social media to offline settings, such as newspapers and television campaigns. Because public responses are essential to our method, we will also incorporate surveys to assess audience reactions and engagement with these campaigns. Investigating how fear-based messaging and public emotional responses manifest in both online and offline environments will provide deeper insights into the broader impact of health communication strategies. In addition, we plan to investigate misinformation within the comments on health organization posts and identify the topics where inaccuracies are prevalent.

Abstract

Background: The media has immense power in shaping public narratives surrounding sensitive topics such as substance use. Its portrayals can unintentionally fuel harmful stereotypes and stigma, negatively impacting individuals struggling with addiction, influencing policy decisions, and hindering broader public health efforts.

Objective: This study aimed to examine how the regional newspaper, The Philadelphia Inquirer, covered events related to illicit drug use between 2013 and 2022, focusing on linguistic patterns and themes associated with specific types of substances.

Methods: We collected a dataset of 157,476 articles published in The Philadelphia Inquirer between 2013 and 2022 and categorized mentioned substances into 8 classes: stimulants, narcotics, cannabis, hallucinogens, depressants, designer drugs, drugs of concern, and treatment medications. From these 157,476 articles, we identified 3661 (2.32%) that mentioned at least 1 substance with potential for misuse. Using dynamic topic modeling, we analyzed thematic evolution in coverage across different drug classes. We then applied aspect-based sentiment analysis to extract the most significant phrases mentioned in each distinct drug class annually and examined the sentiments around these aspects to understand shifting discourse patterns.

Results: Cannabis (1575/3661, 43.02%) and narcotics (1361/3661, 37.17%) dominated the coverage, with 2018 showing peak drug-related reporting (666/3661, 18.19%). Our substance co-occurrence analysis revealed that heroin was most frequently discussed alongside treatment medications (methadone, naloxone, and buprenorphine), reflecting evolving approaches to opioid use disorder. Topic modeling revealed distinct themes across drug classes: legislative and medical aspects dominated cannabis coverage, while narcotics coverage focused heavily on overdose deaths and safe injection sites, particularly during 2017 to 2018. Stimulant coverage centered on feature news and crime-related reporting, while treatment coverage showed an increasing focus on overdose prevention by 2021. The aspect-based sentiment analysis showed that 74.3% (165/222) of extracted aspects were portrayed negatively across all drug classes, with narcotics maintaining consistently negative sentiment throughout the period. However, some drug classes showed notable evolution: hallucinogens demonstrated a marked shift in sentiment score (SS) from negative coverage in 2013 (–0.79 SS) to positive coverage of therapeutic applications by 2021 (+0.47 SS), while cannabis coverage reflected complex societal debates, with industry and business aspects showing strong positive sentiment score peaks (0.64 SS in 2019) even as legislation and policy aspects remained volatile (–0.76 SS in 2013 to 0.61 SS in 2019 and declining to –0.31 SS by 2022).

Conclusions: Our analysis revealed a predominance of negative and punitive language in drug-related news coverage, with limited representation of harm reduction principles. While some drug classes, particularly cannabis and hallucinogens, saw evolving narratives toward medical applications and policy reform, coverage of narcotics remained primarily focused on crime and overdose. These findings suggest a need for more balanced reporting that incorporates harm reduction perspectives and avoids potentially stigmatizing language when covering substance use disorders.

Introduction

Background

The relationship between media representation and public perception is a complex interplay that has profound implications for societal attitudes and policies [1-3]. Media, as a primary source of information for many, has the power to shape, reinforce, or challenge societal norms and beliefs [4,5]. When it comes to issues of public health, such as substance use disorder (SUD), the media's portrayal can either support evidence-based interventions or perpetuate misconceptions and stigmas [6].

Previous research underscores the media's powerful role in shaping perceptions about drugs and issues related to SUD [7-10]. For instance, in the late 1990s in Australia, a program aimed at controlling heroin-related issues faced political defeat, largely due to the media's negative portrayal of heroin users as "deviants" [11]. Similarly, exaggerated media narratives around bath salts overshadowed clinical studies, leading to their prohibition [12,13]. Research by Denham [14] further highlights the media's propensity to motivate moral panics about drugs, even when actual use rates remain stable [14].

Moreover, the media's portrayal of stigmatized subjects, such as illicit drug use, can lead to stigma, discrimination, and reluctance to seek treatment [15,16]. For example, the media often emphasizes punitive measures against users and dealers, potentially influencing public attitudes and behaviors [17-19]. Caburnay et al [16] also found that media coverage can sway individual health behaviors, suggesting its potential impact on attitudes toward drug use.

Harm reduction, a public health strategy, seeks to mitigate the adverse effects of drug use without mandating complete cessation [20]. However, media coverage often lacks a comprehensive view of this approach. A study on Canadian news outlets revealed a tendency to focus on singular, controversial harm reduction strategies [21]. However, when conveyed appropriately, harm reduction messages can significantly diminish the societal repercussions of drug use, especially when they resonate with the audience's values and present a holistic solution [22]. These examples show the importance of critically assessing media representations of substance use, ensuring that they are both accurate and holistic.

Study Rationale and Aims

The pervasive issue of illicit drug use and its associated consequences has been a topic of concern in many urban areas across the United States. The city of Philadelphia has been at the forefront of this crisis, dealing with the devastating effects of drug addiction and its ripple effects on the community. Philadelphia has the second highest rate of overdose deaths (71 per 100,000) in the country [23] and is commonly known as one of the epicenters of the "opioid epidemic" in the United States [24]. In 2021, there were >1250 unintentional drug overdose deaths in Philadelphia [25], the highest number on record. Most of these deaths were caused by opioids, such as heroin and fentanyl [26]. Despite the city's efforts to address the problem, such as expanding access to social services in the hardest-hit neighborhoods, several challenges remain, including the lack of affordable housing and the stigma associated with drug use and SUDs [27]. These challenges can make it difficult for people to seek help [28].

Given Philadelphia's position at the epicenter of the US drug crisis, examining local media coverage becomes crucial for understanding how drug-related issues are presented to the public. The Philadelphia Inquirer, established in 1829, is the city's largest newspaper, with a daily circulation of >100,000 readers, and serves as a primary source of local news coverage. As the third oldest surviving daily newspaper in the United States, it has historically provided extensive coverage of the city's social issues, including public health challenges such as substance use. This study analyzed a decade of coverage (2013 to 2022) from The Philadelphia Inquirer, a period that encompasses significant shifts in drug policy and public health approaches, including the rise of the opioid crisis, the emergence of fentanyl as a dominant threat, and evolving attitudes toward cannabis legalization. This time frame allows us to capture both the intensification of the opioid crisis and the evolution of public health responses to substance use. Our study aimed to understand how The Philadelphia Inquirer's coverage of illicit substances has evolved over time, with particular attention to their framing and contextual portrayal. Specifically, our study addresses 3 research questions (RQs):

- RQ1: How have the characteristics and nuances of mentions related to commonly abused substances evolved over the decade?
- RQ2: In the context of these substances, which overarching themes and subtopics have dominated the discourse, and how have they shifted over time?
- RQ3: What are the multifaceted dimensions, sentiments, and narratives associated with the portrayal of commonly abused substances?

Through this analysis, we seek to understand how media coverage may influence public perception and policy responses to substance use in a major urban center particularly affected by the ongoing drug crisis.

Prior Work

Few studies have investigated the media coverage of illicit drugs and their change over time, particularly in the United States [15,16,29]. A recent study [7] investigating the coverage of illicit drug use by a Canadian newspaper found that it focused on basic social representations, such as attribution of the responsibility for the opioid crisis to a few collectives, including pharmaceutical companies and physicians, or the overall drug supply, and that a shift to less stigmatizing language could positively influence public perception. The study suggests that closer collaboration between the media and the research community is needed to achieve a better understanding of the issue. Ketamine, a psychoactive drug that has attained positive

XSL•FO
RenderX

outcomes in treating severe, treatment-resistant depression, was found to be most associated with themes of abuse, legality, and clinical utility as an anesthetic when it was reported in North American news outlets between 2000 and 2015 [30]. This finding suggests that changes in news media reporting could influence how substances, such as ketamine, are received as viable treatment options, and that guidance is required for journalists on objective reporting of medical research findings.

Google News Archives and cause-of-death records published by the National Center for Health Statistics between 1999 and 2005 were explored for patterns in mentions of the opioid epidemic, and a noteworthy correlation was discovered between the number of news articles and the rates of opioid-related overdose deaths over time [31].

To comprehend the dissimilarities and similarities of media coverage based on drug types, Hayden Griffin et al [19] analyzed 487 news articles published in a national media outlet in Malaysia over a 2-year period. They found that amphetamines, opiates, and cannabis received most of the media coverage, and the discussion of these drugs was primarily in relation to criminal justice. Similarly, Hughes et al [18] conducted a framing analysis of Australian news media coverage of illicit drugs between 2003 and 2008. The study found that criminal justice topics are dominant, but nonlegal issues are also highlighted. The media frames can differ between drugs, with amphetamines portrayed most negatively and cocaine most neutrally. Their findings suggest that sensationalized reporting of drug events is more prevalent during specific episodes and may not be representative of the norm. Our findings do not indicate that The Philadelphia Inquirer uses tactics that sensationalize the current state of drug use in Philadelphia; however, there is a lack of messaging framed around harm reductionist principles or that normalizes evidence-based approaches to substance use.

Methods

Data Collection and Substance Classification

We collected 157,476 news articles from The Philadelphia Inquirer from January 1, 2013, to December 31, 2022, using the *ProQuest* database platform. Each article in our dataset comprises the complete text along with metadata attributes, such as publication date, author, title, links, and subject keywords.

Drug Class Assignment

We compiled our list of substances using the Commonly Used Drugs Charts from the National Institute on Drug Abuse [32], which provides an overview of frequently used legal and illegal drugs. We then classified these substances according to the categories established by the Drug Enforcement Administration [33]. To ensure accuracy in our classifications, we manually reviewed and removed ambiguous terms with multiple meanings (eg, the term “pot” could refer to “flowering pot” or “cooking pot” in addition to marijuana). The Drug Enforcement Administration classifies drugs into 9 categories:

1. Cannabis: marijuana is a mind-altering (psychoactive) drug produced by the cannabis sativa plant. “Cannabis” and “marijuana” are often used interchangeably, resulting in the appearance of cannabis as both the drug class and the drug name.
2. Depressants: these are known to induce sleep, relieve anxiety and muscle spasms, and prevent seizures (eg, barbiturates and sedative-hypnotic substances, such as gamma-hydroxybutyrate).
3. Designer drugs: these are produced illicitly with a slightly altered chemical structure to mimic the pharmacological effects of controlled substances (eg, synthetic marijuana or synthetic cathinones).
4. Drugs of concern: these are unregulated drugs that can be harmful if abused (eg, kratom and xylazine).
5. Hallucinogens: these are derived from plants and fungi and renowned for their capacity to modify human perception and mood (eg, lysergic acid diethylamide, mushrooms, and ecstasy).
6. Narcotics: these refer to opium, opium derivatives, and their semisynthetic substitutes. “Opioid” is a more current and precise term to describe these drugs (eg, heroin, OxyContin, codeine, morphine, and fentanyl).
7. Stimulants: these are drugs that accelerate the body’s functions (eg, methamphetamine, cocaine, and amphetamines).
8. Treatment: these are substances aiding the treatment of opioid addiction (eg, methadone, Suboxone, and naloxone).
9. Miscellaneous: these are substances that can be abused but do not belong to any class (eg, steroids).

Using our mapped list of drug names, we identified news articles that mention any of these drugs in either their title or text. Subsequently, we grouped these articles into clusters based on the respective drug classes. If an article mentioned drugs from multiple classes, we assigned it to all relevant drug classes.

Topic Modeling

To investigate how drug-related topics evolved over time in news coverage, we used dynamic topic modeling [34] using bidirectional encoder representations from transformers topic modeling technique (BERTopic) [35], an advanced method that identifies themes in a corpus of texts. Unlike traditional approaches, such as latent Dirichlet allocation, BERTopic better captures the context and meaning of words, producing more coherent and interpretable results [35]. We analyzed each drug class separately to understand how the coverage of different substances changed over time. Before topic modeling, we implemented several text preprocessing steps to improve the quality of our analysis. We standardized the text by converting all characters to lowercase and expanding contractions to their full form (eg, “don't” to “do not”). We then removed elements that could interfere with the analysis, such as URLs and common stop words (eg, “the,” “and,” as well as “or”) that do not carry significant meaning. These preprocessing steps reduced noise in the data and improved the model’s ability to identify meaningful patterns and topics. A technical limitation of our analysis with bidirectional encoder representations from transformers (BERT) is its maximum token limit of 512 tokens, while the median length of our articles was 749 (SD 573; IQR 511-1014) tokens. However, this limitation aligned well with journalistic writing conventions. News articles typically follow

XSL•FO
RenderX

the inverted pyramid style [36], in which the most newsworthy information appears at the beginning of an article, followed by supporting details. This structure allowed us to confidently use the first 512 tokens of each article, as they typically contained the most salient information and key themes of the full text. This approach allowed us to work within the token limit and retain the essential content for our analysis.

To ensure high-quality results, we refined our analysis through multiple iterations following established topic modeling validation approaches [37,38]. We set specific parameters to optimize topic coherence, including capping the top number of words per topic at 10, and looked for words and phrases that commonly appear together (ie, n-grams) to provide richer context. We evaluated the quality of our results using 3 criteria: topic coherence (measured by a coherence score with a threshold >0.5), topic distinctiveness (minimal overlap in the top 10 keywords between topics), and human interpretability (clear thematic focus discernible from top keywords) [39]. Through iterative refinement, we systematically reduced the number of topics to 4 per drug class based on achieving maximum coherence scores, minimal thematic overlap, and clear interpretability [40].

To characterize and validate the topics generated by BERTopic, we conducted a detailed analysis of the representative articles. For each topic identified, 2 researchers independently examined the top 20 articles with the highest topic representation scores, noting common themes and key narratives. This human analysis helped us understand how the algorithmically derived topics appeared in actual news coverage and enabled us to develop more meaningful topic labels. For instance, when examining articles highly associated with what BERTopic initially labeled as “law enforcement” within the cannabis class, our review revealed a more nuanced focus on legislative processes and policy reform, leading us to refine this topic’s characterization. Disagreements in topic interpretation were resolved through discussion with a third researcher until a consensus was reached. This process of combining computational topic modeling with human analysis of representative articles enhanced our understanding of the thematic evolution in drug-related coverage.

Aspect-Based Sentiment Analysis

We used aspect-based sentiment analysis rather than traditional sentiment analysis because drug-related articles often contain multiple viewpoints and sentiments within the same text. While traditional sentiment analysis assigns a single sentiment score to an entire document, aspect-based sentiment analysis allows us to capture nuanced sentiments associated with specific aspects of drug discourse, for instance, distinguishing between sentiments about law enforcement approaches versus public health initiatives, even within the same article. To extract these aspects from the articles, we used key phrase extraction to identify words and phrases with the highest significance and relevance within each news article. As key phrases encapsulate the essence of an entire document, they serve as essential tools for retrieving critical information from large and diverse datasets [41].

While various tools and techniques are available for key phrase extraction from documents, it is notable that most of these models generally focus on the statistical properties of text rather than semantic similarity [42]. We selected KeyBERT [42] for phrase extraction because of its ability to capture context and identify meaningful phrases. The model combines 3 key components: the TextRank algorithm [43] (which ranks phrases based on their importance within the text), BERT embeddings [44] (numerical representations that capture the meaning of words and phrases), and cosine similarity [42] (a measure of how closely related 2 pieces of text are). To improve accuracy, we used vectorizers (tools that convert text into structured patterns) that analyze grammatical patterns to ensure that extracted phrases were linguistically meaningful. We analyzed articles within each drug class year by year from 2013 to 2022, allowing us to track how key phrases and their associated topics evolved over time. For each article, we compared the extracted phrases with the overall article content using cosine similarity scores, retaining only those phrases that reached a similarity threshold of 40%. We determined this threshold through careful testing, finding that it effectively balanced between capturing relevant phrases and excluding irrelevant or redundant information.

To analyze sentiment, we first located all paragraphs containing each identified aspect, allowing us to focus on relevant content and reduce noise. We then used the NewSentiment model [45], which is specifically designed for analyzing news content, to determine whether the discussion of each aspect was positive, negative, or neutral. This model was pretrained on a large dataset of political news articles [45], making it well suited for analyzing journalistic writing. For each aspect, we calculated a normalized sentiment score (SS) by subtracting the negative sentiment probability from the positive sentiment probability and dividing by their sum, resulting in scores ranging from –1 (most negative) to 1 (most positive). To facilitate interpretation and identify broader patterns, we manually grouped semantically similar aspects into thematic categories for each drug class (eg, “Legislation/Policy,” “Medical Use” for cannabis; “Overdose Prevention,” “Opioid Treatment” for treatment drugs). We then calculated mean sentiment scores and CIs for each aspect group per year, allowing us to track how sentiment toward different themes evolved over time.

Ethical Considerations

This study analyzed publicly available news articles from The Philadelphia Inquirer accessed through the ProQuest database platform. No data involving human participants were collected, analyzed, or stored during this research. All article data were handled in aggregate form, and no personally identifiable information was extracted or analyzed.

Results

Substance Distribution and Co-Occurrence Patterns

Of the 157,476 articles analyzed, 3661 (2.32%) referenced at least one drug class. The distribution of these articles across drug classes and years is shown in Table 1. We observed a steady increase in explicit substance mentions, followed by a decline (COVID-19 pandemic effect, presumably around 2020)

XSL•FO
RenderX

in The Philadelphia Inquirer over the past decade. Cannabis was the most frequently discussed drug class, followed by narcotics (ie, opioids). The annual count of news articles indicates that 2018 saw the highest frequency of drug-related mentions. Narcotics were the second most discussed drug class and the most prevalent in 2017 and 2018, suggesting that the opioid crisis was a major focus of news coverage during those years.

Further analysis of drug mentions by class shows that cannabis is primarily associated with marijuana (Figure 1). Despite the controversial origins of the term “marijuana” [46], it has been consistently used in news articles over the years. Among the depressant drugs, Xanax and Ambien were the most frequently mentioned, likely due to their widespread use for anxiety and sleep disorders and their potential for abuse. Similarly, cocaine and ecstasy were the most frequently mentioned drugs in the stimulant and hallucinogen drug classes, respectively, indicating their enduring popularity.

Table 1. Distribution of articles per drug classes by year.

Year	Cannabis (n=1575, 43.02%)	Depressants (n=106, 2.89%)	DD[a] (n=16, 0.43%)	DC[b] (n=11, 0.3%)	Hallucinogens (n=137, 3.74%)	Narcotics (n=1361, 37.17%)	Stimulants (n=627, 17.13%)	Treatment (n=449, 12.26%)	Total[c] (n=3661, 100%)

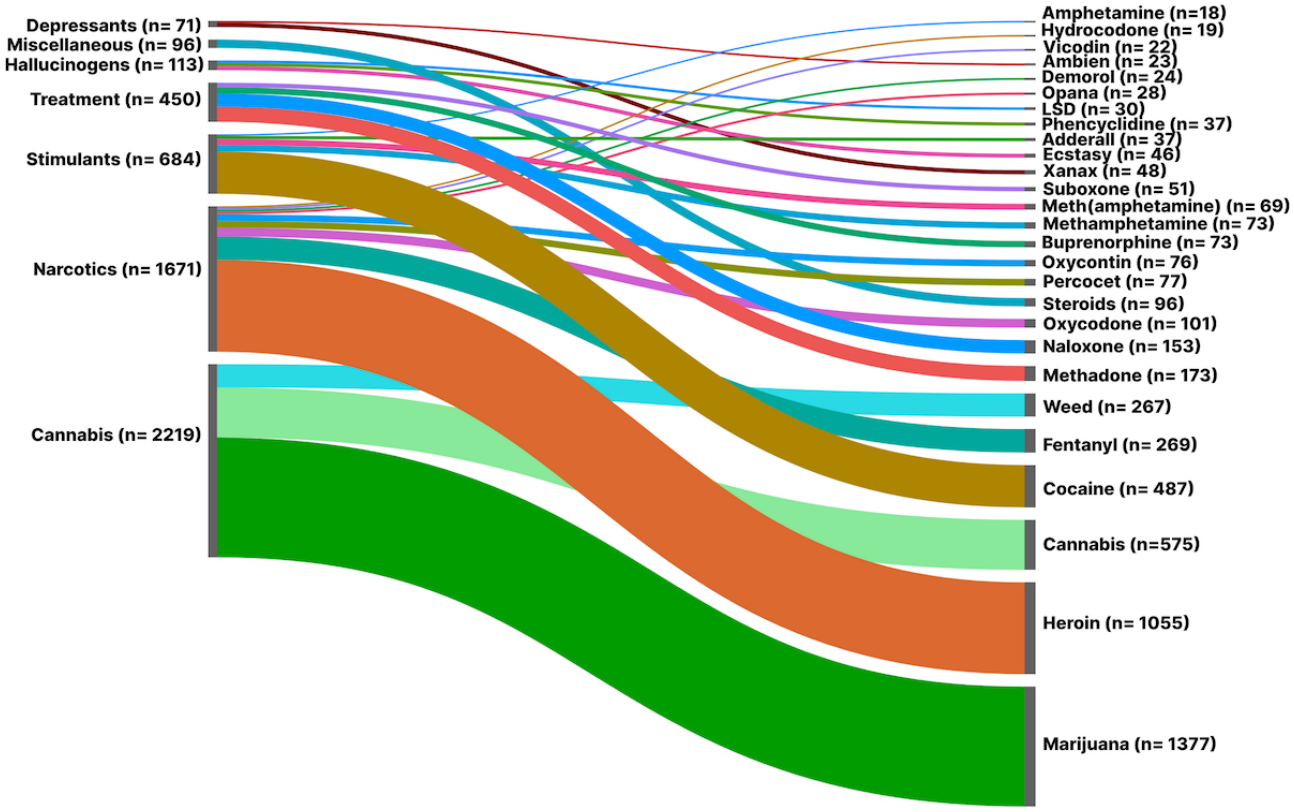
[a]DD: designer drug.

[b]DC: drug of concern.



[c]The total sum of all drug class mentions exceeds the number of unique articles containing substance mentions (n=3661) because individual articles may mention substances from multiple drug classes.

[d]Italicization indicates the most frequent drug class.

[e]Not applicable.

XSL•FO
RenderX

Figure 1. Number of substances per drug class in our dataset. LSD: lysergic acid diethylamide.

Our co-occurrence analysis revealed an association between the frequency with which certain substances are discussed and provisional overdose and use patterns. Table 2 shows that heroin, one of the most prevalent substances in Philadelphia, was overtaken by fentanyl in 2018, buprenorphine in 2021, and buprenorphine and fentanyl in 2022. Furthermore, our analysis indicated that narcotics and treatment drugs, such as methadone, naloxone, and buprenorphine, were the second most commonly colocated drugs in articles. Treatment drugs such as methadone, naloxone, and buprenorphine are viewed as positive and proactive responses to opioid use disorder (OUD) [47]. Buprenorphine, a safe and effective treatment for OUD, emerged in 2020 alongside heroin, followed by cannabis in 2021 and 2022.

Thematic Evolution by Drug Class

Our analysis revealed distinct thematic patterns across different drug classes (Figure 2). For hallucinogen-related coverage, we identified 4 main topics: phencyclidine (PCP) and criminal justice, music and film, feature news (eg, a human-interest story on how a local who experiences posttraumatic stress disorder [PTSD] uses lysergic acid diethylamide to treat their symptoms [48]), and decriminalization and treatment. Criminal justice coverage dominated early discussions in 2013 but showed a marked decline until a substantial spike in 2017. Feature news emerged as a consistent theme throughout the period, peaking in 2016, while coverage of hallucinogens in music and film maintained a relatively stable presence. Notably, discussions of decriminalization and treatment gained increasing prominence from 2019 onward, becoming a dominant theme by 2022.

Figure 2. Topic evolution per class of drug per year. PCP: phencyclidine.

Articles discussing depressants centered on 4 key themes: polysubstance overdose, drug charges involving benzodiazepine, treatment for OUD, and sexual assault cases. Coverage of sexual assault cases saw a dramatic spike in 2014 before steadily declining, while reporting on polysubstance overdose showed cyclical patterns with peaks in 2016 and 2018 to 2019. Benzodiazepine-related charges received heightened attention in early years (peaking in 2014) but diminished over time, while treatment discussions remained relatively steady before showing renewed interest in 2022.

Cannabis coverage demonstrated the most dramatic thematic shifts over the decade. The 4 main topics identified were the medical marijuana program, medical marijuana legalization, drug testing in sports, and marijuana depicted in films. Coverage of the medical marijuana program dominated from 2013 to 2020, peaking in 2018 with nearly 96% (120/125) of articles. However, a significant transition occurred around 2020, when legalization discussions began to overtake program-related coverage. By 2022, legalization had become the primary focus, with about 75% (60/75) of articles, while program-related coverage declined to approximately 20% (15/75) of articles. Sport-related drug testing and film depictions maintained a minimal but consistent presence throughout the period, rarely exceeding >5 articles per year.

Among articles that mentioned narcotics, we observed the following top 4 themes: overdose deaths, safe injection sites, film reviews, and feature news. Coverage around overdose deaths within the city consistently received the most coverage throughout the decade, starting at around 85% (60/70) of the articles in 2013, declining to approximately 66% (30/45) of articles through the mid-2010s, before showing significant spikes in 2018 (>60 articles) and 2022 (>60 articles). Coverage of safe injection sites emerged as a prominent theme around 2017, peaking in 2018 with >30 articles, before gradually declining through 2022. Film reviews (articles discussing a film where narcotics are present) and feature news maintained relatively low but steady coverage, rarely exceeding 5 articles per year.

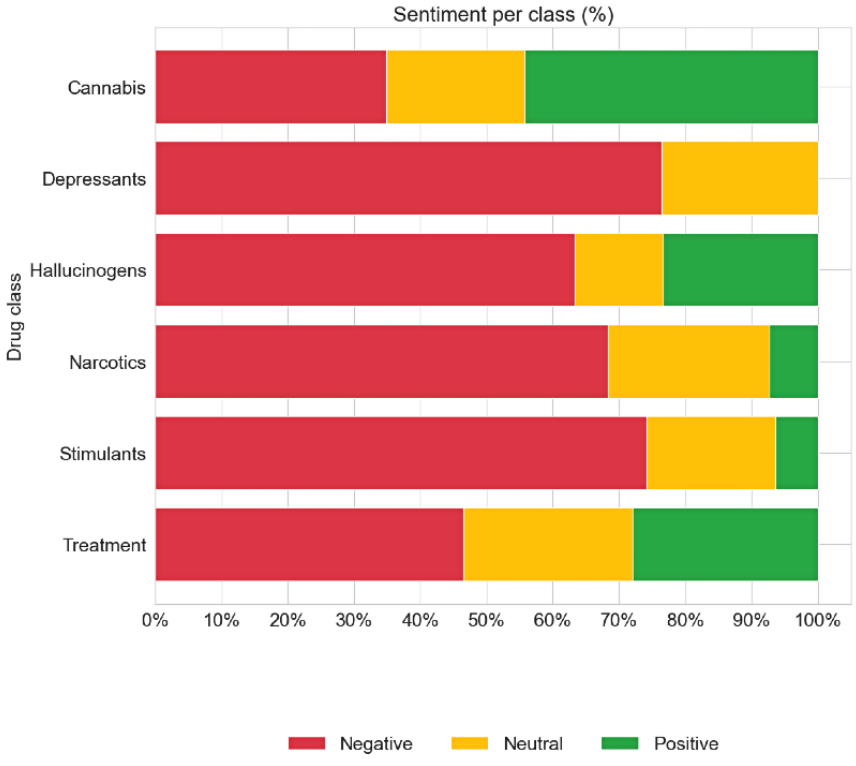
Stimulant-related coverage revealed 4 distinct themes: feature news, Hollywood, sports and substance misuse, and drug conviction. Feature news dominated the coverage, with higher frequency in earlier years (>30 articles in 2013) compared to later years (approximately 15/15, 100% in 2022), with notable fluctuations including a peak of 80% (25/30) of articles in 2016. Coverage related to Hollywood and sports showed higher prominence in earlier years (2013 to 2014) but maintained minimal presence afterward. Drug conviction coverage remained consistently low throughout the period, with slight increases in 2015 and 2019.

Treatment-related coverage demonstrated evolving priorities through overdose prevention, overdose narrative news, the Kensington neighborhood, and urban planning. Most notably, coverage of overdose prevention showed a dramatic increase from 2019 onward, reaching >20 articles by 2021. Overdose narrative news peaked around 2018 to 2019 with about 10 articles per year, while coverage of the Kensington

XSL•FO
RenderX

neighborhood showed heightened attention in 2017 (10/15, 66% of articles). Urban planning maintained relatively consistent but low coverage throughout the period.

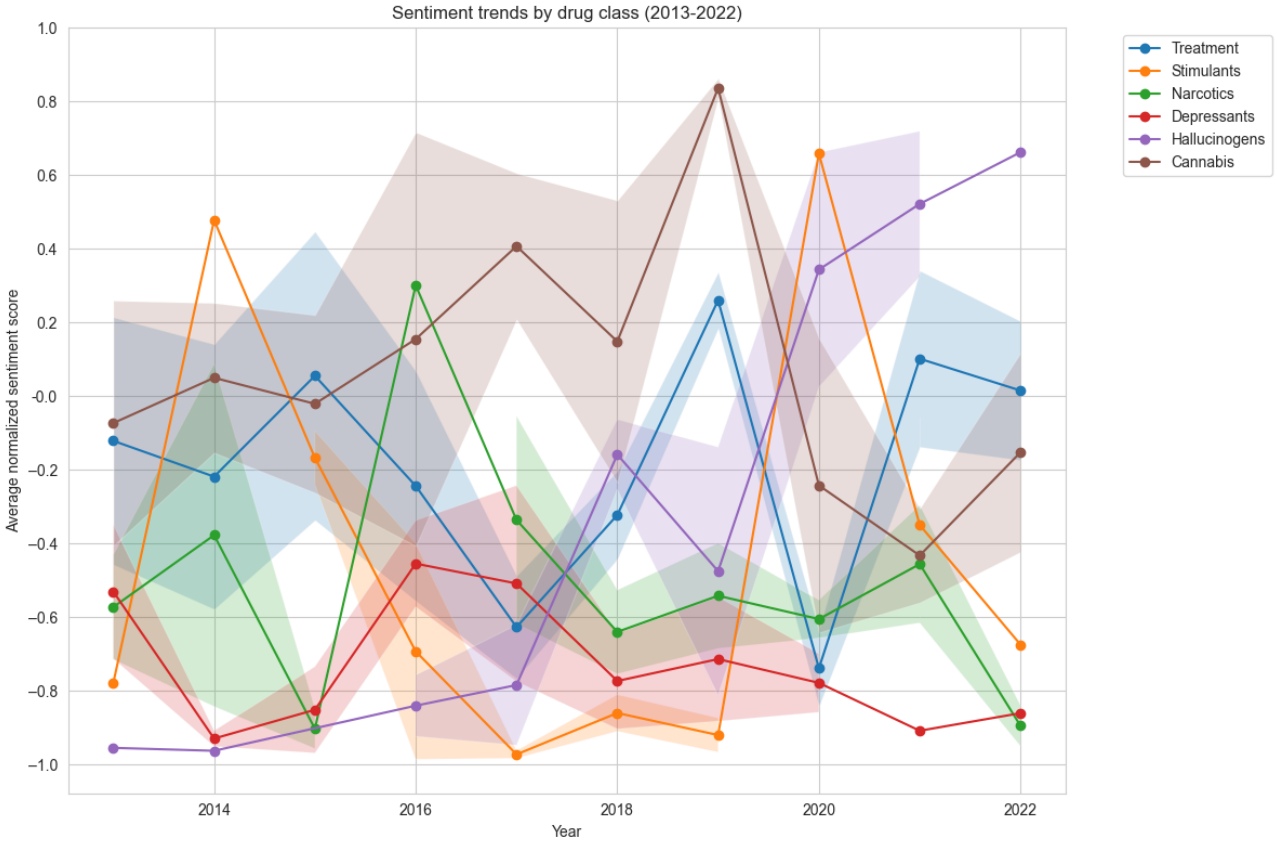
These patterns highlight how coverage of different drug classes responded to evolving public health concerns and policy initiatives. While narcotics coverage maintained a consistent focus on overdose deaths, treatment coverage showed a clear shift toward prevention strategies in recent years. Meanwhile, stimulant coverage demonstrated a broader focus on social and cultural aspects rather than public health concerns.



Sentiment Pattern and Aspect Analysis

Our sentiment analysis revealed distinct patterns across 3 dimensions: overall sentiment distribution by drug class, temporal changes in sentiment, and evolution of thematic aspect groups over time. The overall sentiment distribution (Figure 3) showed cannabis and hallucinogens having the highest proportion of positive aspects, while depressants and narcotics demonstrated predominantly negative coverage. Treatment-related coverage showed a more balanced distribution between positive and negative sentiments, reflecting the complex nature of intervention discussions.

Temporal sentiment patterns (Figure 4) revealed significant evolution in coverage tone across drug classes. Hallucinogens showed the most dramatic positive shift, moving from strongly negative coverage in 2013 to 2014 to increasingly positive coverage by 2022. Cannabis coverage demonstrated considerable volatility but maintained generally neutral to positive sentiment, while depressants consistently received the most negative coverage throughout the period.



Analysis of thematic aspect groups over time (Table 3) provided deeper insight into these sentiment patterns (Figure 5). To facilitate interpretation and discussion, we grouped aspects into thematic categories within each drug class based on semantic similarity. As shown in Figure 5, for cannabis, industry and business aspects showed strong positive sentiment score (SS) peaks in 2016 (0.49) and 2019 (0.64), while legislation and policy aspects evolved from highly negative (–0.76 in 2013) to positive (0.61 in 2019) sentiment scores before declining again (–0.31 in 2022). Medical use maintained a relatively stable, slightly positive sentiment, while regulatory and enforcement aspects remained predominantly negative.

Figure 3. Proportion of aspects with positive, negative, and neutral sentiments per class.

RenderX

Table 3. Aspect groupings by drug class.

Drug class and aspect group	Representative aspects
Cannabis	
Legislation or policy	marijuana legalization, cannabis legislation, marijuana reform, marijuana laws
Medical use	medical marijuana, medical cannabis, medicinal marijuana, medical marijuana program
Industry or business	marijuana dispensaries, cannabis industry, cannabis investments, nascent marijuana industry
Regulatory or enforcement	marijuana convictions, marijuana offenses, recreational marijuana, cannabis impairment
Treatment	
Overdose prevention	naloxone spray, narcan, overdose drug, lifesaving drug, reversal medication
Opioid treatment	buprenorphine prescription, methadone programs, buprenorphine program, prescribing buprenorphine
Crisis response	overdose fatalities, drug costs, opioid crisis, opioid epidemic, drug response
Medical or clinical	opioid painkillers, opioid prescriptions, prescription drugs, opioid use disorder
Narcotics	
Overdose	overdose crisis, overdose victims, fatal overdose, overdose deaths, fentanyl overdoses
Law enforcement	drug possession, federal drug laws, drug convictions, border protection, drug trafficking
Public health	opioid epidemic, aids crisis, public drug use, neonatal abstinence syndrome
Policy or treatment	new jersey drug policy alliance, opioid litigation, drug laws ease, opioid drugmakers
Hallucinogens	
Medical or therapeutic	new psychedelic therapies, psychedelic therapeutics company, new psychiatric medicines
Law enforcement	drug charges, drug arrests, smuggled drugs, illegal psychedelic drugs
Substances	lsd, cannabis, marijuana, psychoactive compounds, crack cocaine
Social context	party drug, prevalent drug use, favorite drug conversation
Depressants	
Medical use	sleep drug zolpidem, insomnia drugs, medical marijuana, lorazepam, using ambien
Overdose or safety	xanax overdose, overdose deaths, overdose statistics, opioid overdoses
Prescription	prescription opioids, benzodiazepines, morphine, zaleplon prescription
Law enforcement	homicide case, county district attorney, montgomery county prosecutors
Stimulants	
Law enforcement	drug violations, cocaine possession, large cocaine distribution ring, drug trafficking
Health or treatment	addiction treatment program, few medication options, antidepressant, methamphetamine use
Crime related	crime spree, customs officials, probation violation
Substance specific	illicit fentanyl, cocaine use, lehtera cocaine, crack cocaine buyer, largest cocaine seizure

XSL•FO
RenderX

Figure 5. Sentiment scores across aspect groups for the drug classes cannabis and depressants. Values represent average sentiment scores ranging from –1 (most negative: red) to 1 (most positive: blue), with white indicating neutral sentiment.

The evolution of cannabis-related sentiment is particularly evident in key legislative and policy aspects (Table 4). Coverage of recreational marijuana use and decriminalization shifted from predominantly negative sentiment in 2013 (with quotes expressing opposition to decriminalization) to increasingly positive coverage by 2019, when discussions focused on potential economic and social benefits. Similarly, marijuana legalization aspects evolved from skeptical coverage in 2013 to 2014 to more supportive framing by 2019, although this positive sentiment declined in later years as implementation challenges emerged. This transformation in coverage tone reflects broader societal shifts in cannabis policy discourse over the decade. This evolution in cannabis coverage is further reflected in the terminology used, where aspects associated with "marijuana" often carried negative connotations, while "cannabis" was framed more positively. For example, the Marijuana Opportunity Reinvestment and Expungement Act's discussion in 2019 used the term "cannabis" when describing positive policy developments (Marijuana Opportunity Reinvestment and Expungement Act of 2019 [49]), while earlier negative coverage of decriminalization by New Jersey Governor Christie used "marijuana" (Inquirer Staff, June 18, 2015, NEW JERSEY: Sharp increase in backing for legalizing marijuana, the Philadelphia Inquirer; Multimedia Appendix 1). Within the cannabis class, "medicinal marijuana" consistently received more positive coverage than "recreational use."

Depressants showed consistently negative sentiment across all aspect groups, with prescription-related aspects showing particularly negative sentiment (–0.87 in 2015 and –0.76 in 2022). Law enforcement aspects improved slightly from –0.52 in 2014 to –0.16 in 2019, while medical use aspects grew increasingly negative over time, reaching –0.59 by 2020 (Figure 5). The overdose or safety category emerged with negative sentiment (–0.26 to –0.54) in later years, reflecting growing concerns about safety risks. The consistently negative coverage of depressants was particularly evident in discussions of combined drug use, especially regarding benzodiazepines with opioids and their associated overdose risks. The sentiment toward "insomnia drugs" notably deteriorated between 2013 and 2016, influenced by growing concerns about prescription policies and pharmaceutical companies' transparency in warning labels (Multimedia Appendix 1).

Hallucinogen coverage showed the most dramatic thematic evolution (Figure 6). While law enforcement aspects maintained strong negative sentiment (–0.79 in 2013 and –0.75 in 2016), medical or therapeutic aspects emerged in later years with notably positive sentiment (0.47 in 2021). As detailed in Multimedia Appendix 1, this shift is particularly evident in the coverage transition from negative associations with crack cocaine (2014) and cannabis (2018) to increasingly positive framing of medicinal cannabis (2019) and new psychedelic therapies (2021). This positive shift in medical or therapeutic aspects may be attributed to recent studies on psychedelic drugs for treating mental health disorders, such as treatment-resistant depression and PTSD. Substance-specific aspects showed gradual improvement from highly negative sentiment (–0.90 in 2014) to slightly negative sentiment (–0.09 in 2021), while social context aspects appeared sporadically with negative sentiment (–0.66 in 2019). Table 5 provides an exemplar excerpt from The Philadelphia Inquirer that reflects this evolution, particularly the positive sentiment regarding the therapeutic potential of hallucinogenic drugs for treating PTSD.

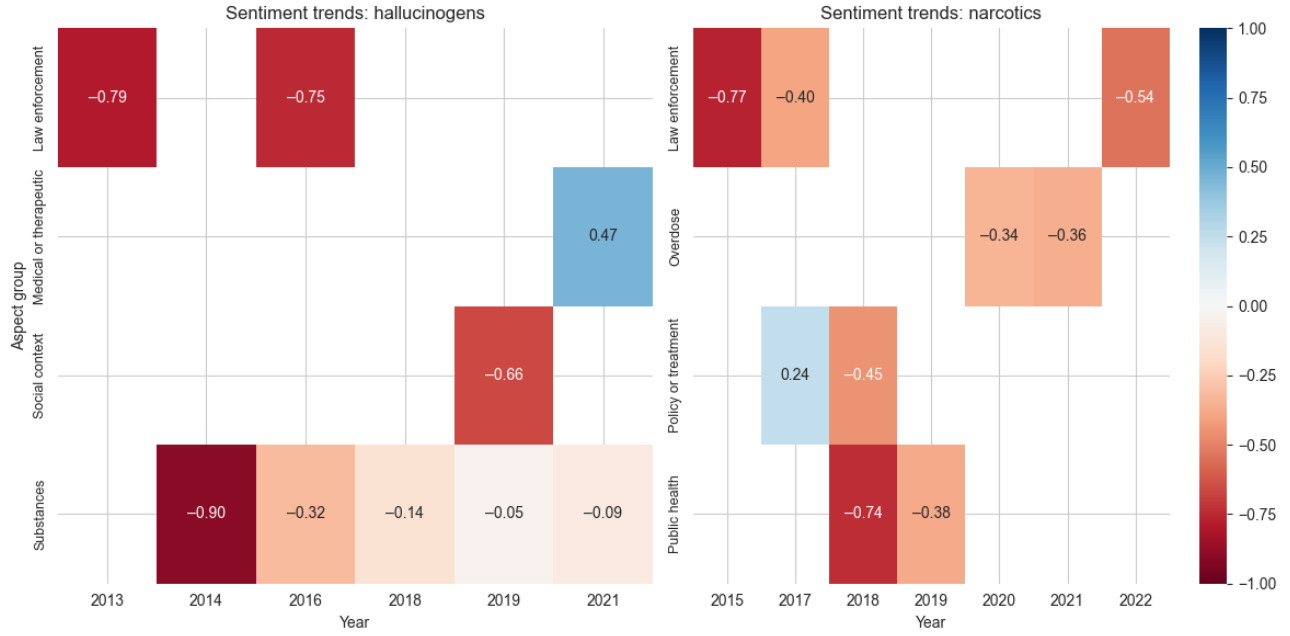
Building on these contrasting patterns, narcotics coverage maintained consistently negative sentiment across all aspect groups (Figure 6). Law enforcement aspects showed persistent negative sentiment, although improving slightly from –0.77 in 2015 to –0.54 in 2022. The overdose aspect group emerged in later years with moderately negative sentiment (–0.34 in 2020 and –0.36 in 2021), while public health aspects improved from –0.74 in 2018 to –0.38 in 2019. Policy or treatment aspects showed brief positive sentiment (0.24 in 2017) before turning

XSL•FO
RenderX

negative (–0.45 in 2018), reflecting the challenges in implementing treatment initiatives.

Similarly negative but with even stronger intensity, stimulant coverage demonstrated some of the most consistently negative sentiment patterns across all drug classes (Figure 7). Crime-related aspects maintained strongly negative sentiment throughout (–0.81 in 2013, –0.91 in 2017, and –0.63 in 2018), while law enforcement aspects showed similarly negative shifts (–0.93 to –0.66 between 2017 and 2019). Substance-specific coverage remained consistently negative (–0.84 to –0.85), although health or treatment aspects emerged in later years with slightly less negative sentiment (–0.22 in 2021).

Table 4. Changes of tone toward marijuana decriminalization.



Article	Aspect	Year	Sentiment
"...Craig T. Steckler, president of the police officers' conference, led his introduction of holder by criticizing the justice department's decision this year not to challenge state laws in Colorado and Washington that allow recreational marijuana use[a]..."	Recreational marijuana use	2013	Negative
"...One question he answered: he said that he disagreed with U.S. Attorney General Eric Holder's memo Thursday saying the Obama administration would not challenge the new marijuana decriminalization[a] laws in Colorado and Washington. 'I think it's a mistake for him to turn his back and essentially by fiat legalize marijuana in Colorado and Washington,' Christie said..."	Marijuana decriminalization	2013	Negative
"...New Jersey is one of 23 states that have legalized medical marijuana despite a longtime federal prohibition against selling or using the drug for medical or recreational reasons...'this federal policy toward state-level marijuana legalization efforts[b] creates a situation in which the medical marijuana industry is in existence, integrating into local, state, and national economies, and employing thousands of people, some of whom are represented by labor unions or involved in labor organizing efforts despite the industry's illegality,' the opinion said..."	Marijuana legalization efforts	2015	Neutral
"...marijuana is a schedule 1 drug, which means the federal government treats it as if it were as dangerous as heroin or lsd and has no medical benefit. The act would also require authorities to remove federal cannabis convictions from millions of criminal records. More than two-thirds of American voters support full [marijuana] legalization[c], according to poll results released Nov. 14 by the Pew Research Center... 'It's the first piece of marijuana cannabis legislation[c] in Congress to move this far. And this could lead to more local reform as well,' said Goldstein, a South Jersey-based organizer for the National Organization for the Reform of Marijuana Laws." Table 5. Example aspects and excerpts of article text with sentiment: "+" denotes a positive sentiment and "–" denotes a negative sentiment.

Type of drugs and aspect; year	Sentiment	Excerpt
Hallucinogens		
"New psychiatric medicines"; 2021	+	"...last summer, the University of North Carolina received nearly $27 million from DARPA, the research arm of the U.S. Department of Defense, to develop new psychiatric medicines from psychedelics...Hopkins, along with New York University, recently completed phase 3 clinical trials with the nonprofit multidisciplinary association for psychedelic studies for MDMA-assisted therapy for PTSD..."
Narcotics		
"Medical marijuana"; 2017	+	"...he said. marijuana helped him with sobriety, and also helped him get off oxycodone and several other medications he was prescribed over the years for the pain caused by his many parachuting missions and the anxiety that PTSD triggered, he said. Karpowich said he participated in at least a dozen protests at the statehouse in Trenton, holding signs and 'ambushing lawmakers' to get them to consider expanding the medical marijuana program. 'veterans have served their country, and no one should tell them they can't use marijuana if it helps them,'..."
"Border protection"; 2022	–	"...he unleashed the worst border crisis in U.S. history. u.s. customs and border protection reported more than 1.7 million encounters with illegal migrants at the southern border, nearly four times the number the year before, the highest annual total on record—including 378,000 who were not from Mexico, Honduras, El Salvador, or Guatemala. seizures of deadly fentanyl more than doubled in 2021, and is closely connected to a surge in overdose deaths, which reached a historic high."
Treatment		
"Drug costs"; 2016	–	"...basic lifesaving medicines that emergency workers use every day are getting so costly, officials are scrambling to figure out how to pay for them. and as patients struggle with drug costs, EMS workers and emergency room doctors are seeing the impact. the price paid by Philadelphia emergency medical services for naloxone, which reverses opioid overdoses, has risen 150 percent since 2013...the opioid epidemic rages and record numbers of people die of overdoses, the cost of generic naloxone has more than doubled..."

Figure 7. Sentiment scores across aspect groups for the drug classes stimulants and treatment. Values represent average sentiment scores ranging from –1 (most negative: red) to 1 (most positive: blue), with white indicating neutral sentiment.

In contrast to these predominantly negative patterns, treatment coverage showed the most varied sentiment patterns, with distinct patterns across different aspect groups (Figure 6). Overdose prevention maintained a positive sentiment in the early years (0.58 in 2013, declining to 0.09 by 2019), while crisis response fluctuated dramatically, shifting from positive sentiment (0.47 in 2013) to negative (–0.64 and –0.57 in 2016 and 2017, respectively), back to neutral (0.01 in 2018), and then negative again (–0.47 in 2020). Medical or clinical aspects showed generally negative sentiment but with notable improvement in 2021 (0.32) before declining again (–0.10) in 2022. Opioid treatment aspects emerged with negative sentiment (–0.47 in 2016) but showed modest improvement in later years (0.22 in 2019 and 0.07 in 2022), suggesting growing acceptance of medication-assisted treatment approaches. The evolution of treatment coverage is particularly evident in the changing focus

XSL•FO
RenderX

on positive aspects over time. Naloxone-related aspects (described as a "life-saving drug") dominated positive coverage from 2013 to 2016, while buprenorphine prescription emerged as a central positive aspect from 2019 to 2021, before shifting to negative coverage due to concerns about misuse and street value (Multimedia Appendix 2). Cost-related aspects, particularly regarding naloxone prices and their impact on emergency medical service workers, contributed to negative sentiment spikes in 2016 (Table 5).

These temporal and thematic patterns reveal distinct evolutionary trajectories in media coverage of different substances and treatments. While some substances, particularly stimulants and depressants, maintained consistently negative coverage focused on crime and risk, others showed notable transitions. Hallucinogens evolved toward increasingly positive coverage centered on therapeutic potential, while cannabis coverage reflected complex societal debates around legalization and medical use. Treatment-related coverage, although variable, suggested growing acceptance of evidence-based interventions despite persistent challenges in implementation.

Discussion

Principal Findings

This study aimed to identify narrative shifts, including topics and sentiment, of drug news reporting within The Philadelphia Inquirer over a 10-year period. By grouping the articles based on drug classifications set by the National Institute on Drug Abuse and using co-occurrence analysis, dynamic topic modeling, and sentiment analysis, we uncovered several key findings. The co-occurrence analysis identified an expected connection between opiate narcotics (heroin and fentanyl) and substances such as cannabinoids or methadone, which are commonly used to alleviate opioid dependency symptoms, such as cravings and withdrawal severity. These findings align with provisional drug use and rise in overdose reported both nationwide [50] and within Philadelphia [51]. The emergence of "cocaine" comentions in 2018 matches the growing concern of opiate or stimulant co-use trends [52], as unintentional overdose deaths often involve the combined use of fentanyl or a stimulant such as cocaine. Buprenorphine, a safe and effective treatment for OUD, emerged in the coverage in 2020, with the most mentions (17 articles that mention buprenorphine in 2022 divided by 94 articles mentioning buprenorphine total, 18.1%) in 2022, likely correlated to policy changes making it more accessible [53].

The dynamic topic modeling revealed a strong focus on overdose deaths in the narcotics class. While we do not find evidence of sensationalism reported in other media studies [7,18,19,54], our analysis revealed a persistent focus on overdose deaths in narcotics coverage. Beyond direct event reporting, we observed substantial coverage of drug portrayals in entertainment media [55,56], suggesting news media's dual role in both reporting and reflecting on drug-related narratives.

Sentiment analysis revealed distinct trajectories for different substances. Cannabis coverage showed a marked evolution from negative to predominantly positive sentiment, particularly around medical applications and legalization. This shift coincided with significant local developments, including public figures' advocacy [57,58] and institutional initiatives [59]. In contrast, depressants and narcotics maintained consistently negative coverage, focusing on risks and criminal justice aspects. Hallucinogens showed the most dramatic positive shift, driven by emerging therapeutic applications, while treatment coverage reflected the complex challenges of implementing harm reduction approaches. These findings highlight the evolving nature of drug-related news coverage and its potential to shape public perceptions and policy discussions, as elaborated in the Implications section.

Implications

These findings have several important implications for both journalism practice and drug policy. Research has established that news media plays a significant role in shaping public perceptions and attitudes [1-5]. Through our analysis of The Philadelphia Inquirer's drug coverage, we track how these potentially influential media narratives have evolved over time. The evolution of cannabis coverage, characterized by a shift from negative to predominantly positive sentiment, particularly regarding medical applications and legalization, demonstrates how media reporting reflects shifting narratives around drug use.

The shift in cannabis coverage coincided with several significant local events in 2018: the admission of cannabis use by a former Philadelphia Eagles player [57], advocacy for recreational legalization by Mayor Jim Kenney [58], and the inaugural Cannabis Opportunity Conference in Philadelphia [59]. These events and the media's increasingly positive coverage of them exemplify the interplay between social change, policy developments, and media narratives.

Conversely, the persistent negative framing of certain substances, particularly in narcotics coverage (eg, "overdose crisis," "overdose victims," and "public drug use"), potentially reinforces stigma that can hinder public health approaches. The rare positive aspects (eg, the "New Jersey Drug Policy Alliance"; Multimedia Appendix 2) in narcotics coverage emerged only in relation to harm reduction initiatives, highlighting the potential challenge of incorporating harm reduction narratives into mainstream media discourse. While fear-based narratives can contribute to moral panic [60], our analysis suggests that balanced reporting can help normalize evidence-based interventions, as seen in the evolving coverage of cannabis and psychedelic therapies [61-63].

The pattern of coverage evolution raises important questions about the media's role in normalizing certain substances [64] while potentially stigmatizing others [65,66]. While cannabis coverage has grown increasingly nuanced and accepting, particularly regarding medical applications, coverage of narcotics remains predominantly negative, often emphasizing criminal justice aspects rather than public health approaches. News outlets have the potential to influence public discourse by providing more balanced coverage that includes harm reduction perspectives while maintaining responsible reporting on public health concerns.

XSL•FO
RenderX

Furthermore, our study found an increasing discussion of naloxone, an overdose prevention medication, and buprenorphine, a safe and effective treatment for OUD. Similar to previous work [67], the increasing coverage of these treatments suggests that news outlets can help to educate the public about evidence-based approaches to drug treatment and policy, which is important in the context of the ongoing opioid overdose crisis [67].

Finally, news outlets can impact policy by reporting on the work being done to reduce harm versus criminality aspects of drug use [17,66,68]. Our findings suggest that shifting news coverage from focusing on law enforcement to emphasizing prevention-oriented solutions may change the public's and nonexpert policy makers' views on drug issues, shifting from blame to more health-focused and harm reduction perspectives [22]. This shift mirrors a broader historical trajectory: while the stigmatization of drug users in the United States historically resulted in punitive policies [69], recent years have seen movement toward public health–oriented policies, such as expanding treatment and supporting overdose prevention laws [70].

However, our analyses reveal that discussions on harm reduction are still limited and have not been a prominent aspect of drug-related news in the past decade. As media coverage continues to evolve, it is hoped that future coverage will increasingly focus on compassionate and effective harm reduction strategies for affected communities and people who use drugs. By avoiding fear-based strategies and promoting balanced narratives, the media can greatly contribute to fostering a more empathetic and informed public discourse on drug use, ultimately influencing policy decisions and reducing harm in affected communities [65,66].

Limitations

Our findings should be interpreted in the context of several limitations. First, our analysis relies on articles from ProQuest's database of The Philadelphia Inquirer, which may not represent the complete set of articles published during this period. This limitation stems from potential gaps in digital archiving and database coverage. Future studies could incorporate multiple database sources or direct newspaper archives to ensure comprehensive coverage.

Second, our study focused solely on news articles published in The Philadelphia Inquirer, and therefore, our findings are specific to this source and its coverage of substance use within Philadelphia and the United States. While this focus provides valuable insight into local media coverage in a city significantly impacted by drug use, it limits generalizability to other regions or media outlets. Further research is needed to explore how the portrayal of substance use in the media varies across different regions and cultures.

Third, while previous research has established connections between news media coverage and public attitudes, our analysis of news did not enable us to evaluate the impact of this news exposure on public opinion regarding the issues. Future studies could combine media content analysis with public opinion surveys to directly measure these relationships.

Finally, the findings of our study do not correlate or imply popularity in use. As shown in Table 1, *designer drugs* and *drugs of concern* are mentioned in only 16 (0.43%) and 11 (0.3%) of the 3661 articles, respectively. Owing to the sparse data on these topics in our corpus, we excluded them from further analysis. Future work could specifically target coverage of emerging substances to better understand their media representation.

Conclusions

This study aimed to explore how The Philadelphia Inquirer, a prominent local newspaper covering Philadelphia, a city known nationwide for its ongoing drug crises, mentions commonly abused substances and how the narrativity and sentiment around these drugs change over time. To do so, we analyzed news articles published in The Philadelphia Inquirer between 2013 and 2022, using co-occurrence analysis, dynamic topic modeling, and aspect-based sentiment analysis, and found that cannabis was the most frequently discussed drug class, followed by narcotics. Aspects reported with hallucinogenic drugs tended to have a more positive tone compared to other categories of drugs, while articles on narcotics were the most negative. We also observed a significant focus on overdose and death-related aspects, but there was a noticeable lack of coverage related to harm reduction principles. This study highlights the linguistic shifts reported across various drug classes. It provides compelling evidence of the influence that news media outlets have in shaping discourse around drug use. This, in turn, contributes to creating a more informed and compassionate society, ultimately reducing the harm associated with drug use.

Acknowledgments

We gratefully acknowledge Dr Shahin Jabbari for his valuable support. This work was supported in part by the Institute of Museum and Library Services (IMLS) under grant number RE-246450-OLS-20. We also appreciate the reviewers for their thoughtful and constructive feedback.

Data Availability

The metadata of our dataset, codes, and results of this study are available in the Drugs in Inquirer repository [71].

Abstract

Background: Abortion access in the United States has been in a state of rapid change and increasing restriction since the *Dobbs v Jackson Women's Health Organization* decision from the US Supreme Court in June 2022. With further constraints on access to abortion since *Dobbs*, the internet and online communities are playing an increasingly important role in people's abortion trajectories. There is a need for a broader understanding of how online resources are used for abortion and how they may reflect changes in the sociopolitical and legal context of abortion access. Research using online information and leveraging methods to work efficiently with large textual datasets has the potential to accelerate knowledge generation and provide novel insights into changing abortion-related experiences following *Dobbs*, helping address these knowledge gaps.

Objective: This project sought to use natural language processing techniques, specifically topic modeling, to explore the content of posts to 1 online community for abortion (r/abortion) in 2022 and assess how community use changed during that time.

Methods: This analysis described and explored posts shared throughout 2022 and for 3 subperiods of interest: *before the Dobbs leak* (December 24, 2021-May 1, 2022), *Dobbs leak to decision* (May 2, 2022-June 23, 2022), and *after the Dobbs decision* (June 24, 2022-December 23, 2022). We used topic modeling to obtain descriptive topics for the year and each subperiod and then classified posts. Topics were then aggregated into *conceptual groups* based on a combination of quantitative and qualitative assessments. The proportion of posts classified in each conceptual group was used to assess change in community interests across the 3 study subperiods.

Results: The 7273 posts shared in r/abortion in 2022 included in our analyses were categorized into 8 conceptual groups: abortion decision-making, navigating abortion access barriers, clinical abortion care, medication abortion processes, postabortion physical experiences, potential pregnancy, and self-managed abortion processes. Posts related to navigating access barriers were most common. The proportion of posts about abortion decision-making and self-management changed significantly across study periods (P=.006 and P<.001, respectively); abortion decision-making posts were more common before the *Dobbs* leak, whereas those related to self-management increased following the leak and decision.

Conclusions: This analysis provides a holistic view of r/abortion posts in 2022, highlighting the important role of online communities as abortion-supportive online resources and changing interests among posters with abortion policy changes. As policies and pathways to abortion access continue to change across the United States, approaches leveraging natural language

XSL•FO
RenderX

processing with sufficiently large samples of textual data present opportunities for timely monitoring, with the potential to reflect a broad range of abortion experiences, including those of people who have limited or no interaction with clinical abortion care.

Introduction

Overview

Abortion access in the United States has been in a state of rapid change and increasing restriction since the *Dobbs v Jackson Women's Health Organization* (*Dobbs*) decision in June 2022 [1]. While many people across the United States faced various challenges to accessing abortion before *Dobbs*, with this decision, the legal protection of abortion at the federal level in the United States was removed, returning control to individual states [2]. Since this change, >20 states have entirely or largely banned legal abortion [3], abortion clinics have closed across the United States, remaining and emerging clinics have struggled with the burden of demand resulting in long wait times, and many people have been unable to access in-clinic abortions [4-6]. Given the relative recency of *Dobbs*, the progressive and rolling impacts that have resulted from that decision, and the potential for a national ban on abortion, researchers seek to monitor the impacts of *Dobbs* to provide timely insights [5,7,8]. Research using online information and leveraging methods to work efficiently with large datasets of user-generated text has the potential to accelerate knowledge generation and offer meaningful insights into online behaviors and changing interests related to abortion. We present background describing the importance of online health communities related to abortion and research exploring people's use of these communities, with a specific interest in how natural language processing (NLP) techniques can further this area of research.

Use of the Internet and Online Health Communities for Abortion

People experienced various challenges to abortion access before *Dobbs*, and as such, they sought support to help navigate the processes of abortion decision-making and access [9]. Many people discover pregnancies and make decisions about abortion outside of clinical contexts [10]. In addition, there are many people considering, seeking, and having abortions in the United States who never interact with formal clinical abortion care [11-13]. The internet, particularly with increasing accessibility in recent decades, plays an important role in people's abortion decision-making and navigation. Research has shown that the internet is an important source of abortion information among adults in the United States, particularly for people living in contexts with more abortion restrictions [10,14-18]. With further constraints on abortion access, the internet is likely playing an increasingly important role in people's abortion trajectories as a source of information, peer interaction, social support, health services, and medication [10,14-17]—but more information is needed about the specifics of its use since *Dobbs*.

Online health communities, or online groups of people with a common health interest or purpose governed by a set of policies or norms, are one internet-based resource that people use for abortion-related support [19]. Reddit is a popular social networking site used by approximately one-quarter of adults in the United States in 2022 [20]. Within Reddit, user-generated content is aggregated and dispersed across millions of user-created and monitored message boards on specific subjects (or subreddits; r/subject) to which users can subscribe as members. Members can post material (text, images, videos, or links) with generous character count limits (40,000 characters, approximately 5000-10,000 words), which other members interact with using comments and an upvote and downvote system. Each subreddit is governed by a set of moderators elected from within the community who set subreddit-specific guidelines for posting content, review posts to ensure that those guidelines are being met, and have the option to delete noncompliant posts and ban deviant users. Some subreddits have developed around health topics and function as online health communities.

We chose Reddit as the focus for this research given its popularity and the uniquely valuable window that it offers into how people discuss health concerns outside of formal research settings or clinical encounters. Reddit provides anonymity with its use of pseudonyms and usernames, lack of requirement for users to share personal information in the creation of profiles, lack of collection of IP address information, and lack of restriction on the use of "throwaway" accounts (ie, temporary accounts created for a specific, single use or short-term purpose). These features allow users to engage in more open and honest discussions than they might on other social networking sites [21-23] or with family members or health care providers [24-26]. As a public, user-driven platform, Reddit enables peer-to-peer information exchange and emotional support, often among individuals who may face stigma or lack access to trusted clinical support. This makes it particularly appealing for communication about stigmatized and politicized health experiences such as abortion.

The r/abortion subreddit is a community that aims to "offer support and advice to people who are seeking or have had an abortion." In 2022, r/abortion had almost 45,000 members and was actively moderated by the Online Abortion Resource Squad (OARS), a group that trains volunteers and works to offer consistent, quality information and support to people coming to r/abortion [27]. The group of moderators working with OARS also actively enforces the r/abortion community rules. Previous research has established that people use online communities, particularly those on Reddit, to communicate about abortion decision-making; challenges to abortion access; taking action to end a pregnancy outside of clinical contexts, or self-managed

XSL•FO
RenderX

abortion (SMA); sharing experiences and advice; and needs for support [28-37]. These studies have used qualitative methods to analyze a defined subsample of content, with either a topical query (eg, mention of "abortion" [33]) or a narrow temporal focus (eg, posts from the previous 2 weeks [28,34]). While these qualitative analyses have allowed researchers to explore the nuances of abortion experience and communication in online communities, their scopes provide limited information about the range of uses for this community or any changes in use over time.

Abortion Research Using Machine Learning and NLP Techniques

Researchers with an interest in health behaviors and outcomes have quantitatively explored the use of online communities, including subreddits, for some topics related to sexual and reproductive health, including patient perceptions of prenatal diagnostic testing [38], disclosure and use of throwaway accounts when posting about parenting [39], perceptions of the human papillomavirus vaccine [40], discussion of sexually transmitted diseases [41], the use of message boards related to miscarriage and stillbirths [42], and discussions of contraception [43]. Some of these analyses have used machine learning tools to analyze the textual data. Similarly, other projects have used computational methods to explore discussions of abortion on social networking sites with an interest in assessing and improving research approaches, often using abortion as a test case for a polarizing and complex topic of communication in these spaces [44-47]. In addition, a recent study by Valdez et al [48] explored a subset of posts to r/abortion and r/AbortionDebate in early 2022 and found that these online communities were used differently, with r/abortion often serving as a place to seek and share abortion support and r/AbortionDebate as a platform to debate abortion attitudes. These quantitative analyses and the qualitative approaches described previously demonstrate that data from online communities can provide insights into population interests and needs, as well as into how these communities serve as sexual and reproductive health resources.

However, research using machine learning tools with an explicit interest in abortion as a health concern impacted by sociopolitical context is lacking. Machine learning tools present a particularly compelling opportunity to advance public health research, providing timely and holistic information about how people have used online communities for abortion. Machine learning has a range of applications, including speech recognition, medical diagnosis, and NLP [49]. NLP seeks to process and analyze large amounts of language data—both text and spoken—to understand, interpret, and generate human language meaningfully and with consideration of context. There are many techniques within NLP, including tokenizing text into smaller units, recognition and tagging of parts of speech, text classification, topic modeling, and word embeddings [49,50]. Similar to other machine learning techniques, NLP can be carried out with varying levels of human input. However, when human expertise is particularly crucial, a "human-in-the-loop approach"—or a collaborative approach in which humans and machines work together—can be used [51]. NLP techniques create the potential for accelerated analyses of large samples of language data compared to traditional qualitative analyses and have been leveraged by public health researchers to explore a range of topics [38,39,41,43,45,52-56]. However, to date, there are no applications of NLP techniques to analyze online communication about abortion focused on the *Dobbs* decision as a public health concern, leveraging content expertise with a human-in-the-loop approach.

Research Aims

With ongoing changes to abortion access in the United States and people's use of online communities for abortion, research exploring how people use these communities can provide important insights for researchers, care providers, advocates, and policy makers. Past research has explored relatively narrow aspects of online community use related to abortion or as a topic for a research case study. However, there is a need for a broader understanding of how this type of online community is used for abortion and how it may reflect changes in the sociopolitical and legal context of abortion access. Particularly given the rapidly changing landscape of abortion policy and access in 2022, with uncertainty and increasingly constrained pathways to care, online resources likely play a key role in providing access to information, support, and services. In addition, exploring people's use of online communities for abortion has the potential to provide timely insights from populations that may be hard to reach and not well represented by much of the research on abortion experiences [57-59].

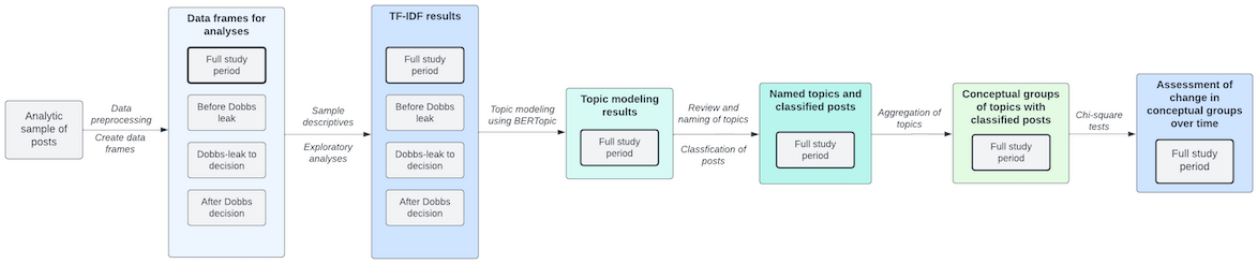
Using NLP techniques to analyze text shared in online abortion communities can help address these gaps, allowing for efficient analysis and pattern detection in the large bodies of user-generated narratives shared in these digital spaces. As such, this research sought to use NLP techniques to explore the content of posts to 1 online community for abortion (r/abortion) in 2022 and assess whether the use of the community changed during that time. Specifically, we used unsupervised topic modeling on posts submitted during the year surrounding the *Dobbs* decision (6 months before and after June 24, 2022) to inductively discover the topical content of posts, integrating a human-in-the-loop approach in the quality review, naming, and aggregation of topics.

Methods

Overview

Reddit data have historically been accessible through free, publicly available application programming interfaces (APIs). Researchers have often used Pushshift's Reddit API and Reddit's official API to obtain compiled information about content shared on Reddit, including creation date, submission (post or comment) text, community interactions (likes, upvotes, and downvotes), and more. Each API had different capabilities but generally provided access to organized and cataloged Reddit data that could be queried to obtain datasets for analysis.

A previous analysis of r/birthcontrol used data obtained from Pushshift's Reddit API [60], as have various other analyses focused on health-related use of Reddit [54-56,61-63]. Given changes to Pushshift's Reddit API in December 2022, specifically issues preventing direct access to any post



XSL•FO
RenderX

submission data from before November 3, 2022, we used 2 different data access approaches to obtain data for this analysis—one for data from December 24, 2021, to August 23, 2022 (gathered and stored for cleaning and analysis in 2022), and another for data from August 23, 2022, to December 23, 2022 (gathered and stored for cleaning and analysis in 2023). Notably, in April 2023, Reddit changed its data access policies, so public access to complete Reddit data through APIs, and the methodology outlined in this manuscript, is obsolete. We chose a start date of December 24, 2021, for this analysis to provide data for 6 months before and 6 months following the Dobbs decision. Details of the data collection approach and methods used for this analysis are presented in Multimedia Appendix 1 [64-68].

A visual overview of the analytic approach used in this research is presented in Figure 1. After procuring complete data from Reddit's API, we implemented additional restrictions to obtain the analytic sample used for this research. These restrictions aimed to provide a sample of posts theoretically within the public domain, containing sufficient text to support contextualized NLP analysis. Sequentially, we excluded posts if they were removed, were deleted, contained only an image, contained only a link, or contained <30 characters. We then cleaned content in this analytic sample to remove usernames, which were replaced with a unique submission ID created for this analysis. These deidentified data were used for the analyses described. The broad sample of posts obtained provides a holistic view of the topics discussed by r/abortion community members in relation to their abortion-related questions, experiences, challenges, and more following the Dobbs decision and related changes in abortion access in the United States in 2022. Comments responding to original posts were not included in this analysis.

To prepare our data for NLP analyses, we cleaned data from posts using part-of-speech tagging, removing links, removing punctuation, changing all text to lower case, removing words with ≤2 characters, and removing stop words.

Figure 1. Methods process flow for natural language processing of posts to r/abortion from December 24, 2021, to December 23, 2022. TF-IDF: term frequency–inverse document frequency.

Analysis

We began this analysis by counting all included posts submitted to r/abortion during the study period by date to summarize the community's overall use during the year. We then described the textual data from posts in our analytic sample for the year-long study period using the following: count of posts (by day and study period), average word count of text in posts, number of unique accounts that posts were made from, and average number of posts per author.

We determined distinctive words and phrases in posts using count vectorization [64,65], applying word frequency analysis to posts from the year and within 3 subperiods of interest in 2022 for this research: *before the Dobbs leak* (December 24, 2021-May 1, 2022), Dobbs leak to decision (period from the *Dobbs* leak to the decision; May 2, 2022-June 23, 2022), and *after the Dobbs decision* (June 24, 2022-December 23, 2022).

Topic Modeling

Overview

Topic modeling can discover latent topics, or themes, in documents. For this analysis, each post was defined as a document for topic modeling, and each data frame represented a set of documents. BERTopic was used given its capacity to account for the contexts of words in sentences in text, extending traditional topic modeling approaches that do not account for the semantic relationships between words [66]. It also provides various opportunities to explore topic hierarchies, topic visualization, and topic analyses. BERTopic was applied to preprocessed post text. Topic numbers, labels (top 10 words), and associated documents were reviewed by a research assistant and the lead researcher to assess model coherence. We manually reviewed a random sample of approximately 20% of all posts for a topic unless a topic had <50 posts, in which case review was completed for all posts in that topic. During this review process, we also developed and assigned a descriptive name for each topic based on the topic label and the raw text of representative submissions. Outlier documents were grouped into an outlier topic group (labeled as −1) in the modeling process and excluded from further review and analysis [67].

While BERTopic generates topics under the assumption that documents can include multiple topics, our categorization approach only assigned each submission to the topic that it had the highest probability of being in (rank 1 topic classification). This approach provided a single topic assignment for each document, reflecting the single most dominant topic describing that post. We reviewed posts classified under each topic to check the quality of assignments and then obtained counts to ascertain the number of posts classified under each topic. Using the trained models, we categorized all r/abortion posts using predictions in BERTopic [68]; classification was conducted using raw post text.

XSL•FO
RenderX

Topic modeling was carried out inductively, yielding results that we reviewed to determine a rigorous and consistent approach to topic aggregation. After reviewing topic labels and representative documents, it was clear that, while many topics used distinctive words, they described similar concepts. As such, we were interested in aggregating topics into *conceptual groups*, or clusters of related topics grouped into broader themes or domains that described key concepts represented by the topics in each model. Conceptual group assignments were manually determined for all topics using an approach that combined dendrogram results (quantitative) with a manual review of submission texts (qualitative), with a focus on defining conceptually meaningful and interpretable groups of topics. Post counts for each conceptual group were obtained based on the summed rank 1 classification assignments for topic modeling results, summarizing the commonality of submissions in each conceptual group.

Assessing Changes in Conceptual Group Frequency Over Time

We used counts of posts in each conceptual group for the year to assess the proportion in each group and differences between the subperiods of interest (*before the Dobbs leak*, *Dobbs leak to decision*, and *after the Dobbs decision*). We assessed statistically significant differences in the proportion of posts in a conceptual group using chi-square tests in R (*chisq.test* package; R Foundation for Statistical Computing). This compared the proportion of posts in a conceptual group versus those not in that conceptual group across the 3 study subperiods, assessing whether there was a change in the frequency of posts primarily focused on that concept throughout 2022. This component of the analysis sought to describe any changes in the primary focus of r/abortion submissions during 2022 considering the dramatic changes to the legal and social environment for abortion during the year

Ethical Considerations

The collection and analysis of these data was exempted from review by the Committee for Protection of Human Subjects at the University of California, Berkeley (2022-08-15585). As data were publicly available and Reddit content is accessible without an account, we did not obtain informed consent from r/abortion users. However, users may still engage with this platform with the expectation of privacy, and ethical principles related to informed consent, participant confidentiality, and privacy still arise when using data from Reddit [69-71]. These are of particular concern given the sensitivity of abortion narratives and the potential for digital data to be used to support abortion-related prosecution [72,73]. While past research using Reddit data has used techniques such as the exclusion of usernames and rephrasing or paraphrasing of post text to protect user identities [53,74,75], these approaches have generally been found to be insufficient to protect user identities, with the capabilities of various online search tools to discover users through the content they posted [76]. The current best practice when conducting research using Reddit data is to engage in a "heavy disguise" process with rigorous testing to produce disguised stories, as described by Reagle [76]. These concerns are especially pressing in the post-*Dobbs* era, where digital information may be weaponized in legal proceedings.

To mitigate these risks, we adhered to the current best practices for ethical internet research using sensitive data on health topics. We maintained the name of the subreddit that the data were obtained from given its visibility as an abortion community on Reddit and its relatively high number of members, offering some level of shielding for individual users [69]. While all analyses were carried out using complete text from submissions, we used an ethical fabrication process to develop representative narratives called "composite quotes" [76,77]. We gathered representative posts for a specific topical area of our findings and used them to generate a composite narrative related to that particular facet of an abortion experience. We replaced keywords, adjusted sentence ordering, and combined details of experiences across individuals. Once a composite quote was generated, its discoverability was checked by searching the overall quote and each sentence on Google (including the terms "Reddit AND abortion AND [the searched text]"), Reddit, and the Pushshift Reddit Search Tool [76,78]. Once composite quotes were checked via searches, a plagiarism checker was used as a final check to ensure that these stories were effectively nondiscoverable using current tools [79]. As such, all stories presented throughout this paper are composite quotes intended to reflect and represent the narratives shared in r/abortion but include a degree of ethical abstraction. This approach reflects a broader ethical stance that recognizes the public and private ambiguity of online data and the evolving legal risks of sharing abortion experiences online. Research in this area must not only comply with institutional review board standards but also grapple with new forms of digital vulnerability, especially in politically charged contexts.

An interdisciplinary team of researchers and advocates conducted this research, grounded in the principles of reproductive justice and the premise that abortion access is a health and human rights concern. To ensure transparency and provide context for our perspectives, we offer individual positionality statements. EP is a female-identifying individual who resided in an abortion-protective US state during the research. She is a Reddit user who primarily reads content. NP is a female-identifying individual who lived in an abortion-protective US state at the time of the study. She does not use Reddit but brings extensive experience working on sexual and reproductive health in abortion-restrictive countries. CM is a female-identifying person who lived in an abortion-protective US state at the time of this research; she is not a Reddit user. UU is a female-identifying person who lived in an abortion-protective US state at the time of this research; she is a Reddit user who primarily reads content. CC is a male-identifying individual who resided in an abortion-protective US state during the research period. He is an active Reddit user.

Our team brought varying levels of experience with Reddit, which enriched our engagement with data from r/abortion and informed our analysis. While all team members were living in abortion-protective states during the study, several of us have personal or professional ties to regions with more restrictive abortion policies. These experiences influenced how we

XSL•FO
RenderX

approached the data, interpreted the results, and framed our findings.

Results

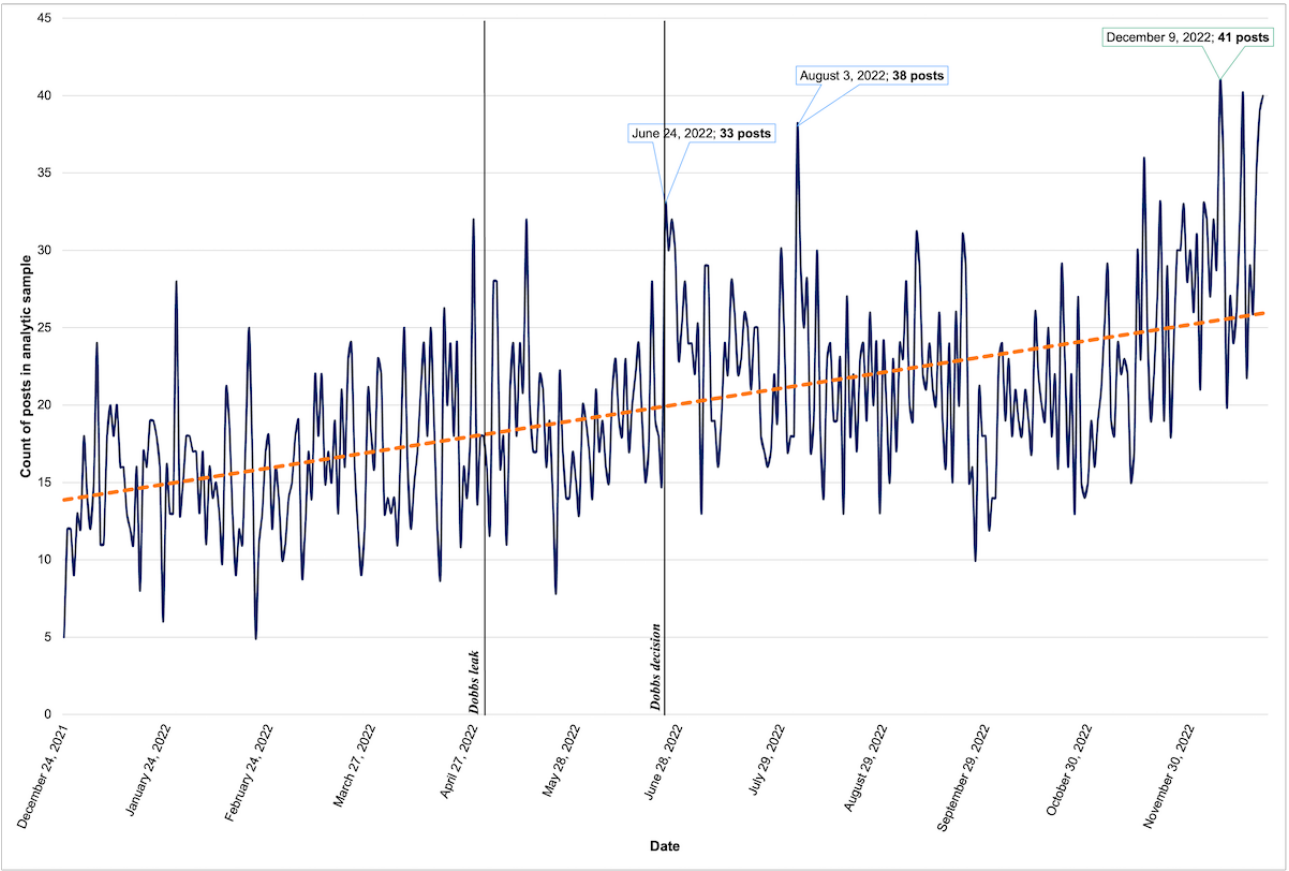
Descriptive Statistics

Of the 12,509 posts shared in r/abortion during the study period (December 24, 2021-December 23, 2022), 2351 (18.79%) were deleted by the users, 1349 (10.78%) were deleted by the user and removed, and 1484 (11.86%) were removed (Table 1). Therefore, 41.44% (5184/12,509) of all posts were elided content and not eligible for analysis. Of the eligible posts, only 0.01% (1/12,509) contained only a link, and a small portion (51/12,509, 0.4%) contained <30 characters. This provided an analytic sample of 7273 eligible posts for the study year.

Table 1. Analytic samples of posts for the year and each subperiod, with counts of elided and excluded submissions (N=12,509).

	Before the *Dobbs* leak (December 24, 2021-May 1, 2022; n=3650)	*Dobbs* leak to decision (May 2, 2022-June 23, 2022; n=1828)	After the *Dobbs* decision (June 24, 2022-December 23, 2022; n=7031)	Year total
Elided content[a], n (%)	1586 (43.45)	829 (45.35)	2769 (39.38)	5184 (41.44)
Deleted by user[b]	572 (15.67)	267 (14.61)	1512 (21.5)	2351 (18.79)
Deleted by user+removed[b]	867 (23.75)	288 (15.75)	194 (2.76)	1349 (10.78)
Removed[b]	147 (4.03)	274 (14.99)	1063 (15.12)	1484 (11.86)
Posts excluded from the sample, n (%)	11 (0.3)	4 (0.22)	37 (0.53)	52 (0.42)
Contained only an image	0 (0)	0 (0)	0 (0)	0 (0)
Contained only a link	1 (0.03)	0 (0)	0 (0)	1 (0.01)
<30 characters	10 (0.27)	4 (0.22)	37 (0.53)	51 (0.41)
Elided+excluded posts, n (%)	1597 (43.75)	833 (45.57)	2806 (39.91)	5236 (41.9)
Posts in sample, n (%)	2053 (56.25)	995 (54.43)	4225 (60.09)	7273 (58.14)
Posts per day, median (IQR)	16.0 (5.5)	18.0 (5.0)	23.0 (8.0)	19.0 (8.0)

[a]The proportion of content removed by Reddit in this case aligned with previous accounts from Reddit on their removal of content (6% in 2020). While there is no systematic accounting of content deleted from Reddit, research on the 3 most popular sensitive-topic subreddits found that approximately half of the content was deleted by users [80], a higher proportion than that observed in these data from r/abortion.



[b]Deleted content refers to posts removed from Reddit by the original poster. Removed refers to posts that were removed by Reddit or r/abortion moderators, and Deleted by user+removed refers to content that was both removed by Reddit or r/abortion moderators and then deleted by the user. Categories are exclusive.

The highest daily volume of posts was on December 9, 2022, with 41 eligible submissions (Figure 2). As there were no substantive policy, political, or social events related to abortion at this time (except for the legalization of abortion in Argentina), we believe that this peak is a random date in a larger upward trend. Other peak dates for post submissions were June 24, 2022 (33 posts; the date of the *Dobbs* decision), and August 3, 2022 (38 posts). The median number of eligible posts throughout the year was 19 (range: 5-41, IQR 8) per day, and the median number of posts per period increased throughout the year, with 16 posts per day before the *Dobbs* leak, 18 posts per day between the leak and the decision, and 23 posts per day following the *Dobbs* decision. Posts in the analytic sample had a median of 53 words per submission across the year (range 2-3204).

Posts were shared from 4468 unique accounts during the year, with posts made by 1379 users before the leak, 702 users between the leak and the *Dobbs* decision, and 2620 users following the *Dobbs* decision. On average, posters shared <2 posts in the r/abortion community during the year from a single Reddit user account (mean 1.6; IQR 0.5-1.6), with slight variation across subperiods.

XSL•FO
RenderX

Figure 2. Line graph showing daily volume of posts to r/abortion in 2022, with markers for the dates of the Dobbs leak and decision (N=7273 posts). The highest daily volume of posts was observed on December 9, 2022 (n=41 posts). Other peak dates for post submissions were June 24, 2022 (n=33 posts; the date of the Dobbs decision), and August 3, 2022 (n=38 posts).

Analyses of Cleaned Submission Text

Exploratory Data Analyses: Count Vectorizer Results

We obtained distinguishing sequences of consecutive words of different lengths, known as uni-, bi-, and trigrams ("n-grams"), from posts. These topics included abortion decision-making timing and feelings, which commonly included "feel," "want," "baby," "know," "pregnant," and other words (see Multimedia Appendix 2) [81] for the year and by study period in relation to the *Dobbs* leak and decision. For the year overall (N=7273 posts), n-grams reflect discussions of pregnancy and pregnancy confirmation, abortion timing and decision-making, and access through clinic-based and online care. Throughout 2022—in yearly results and across subperiods—n-grams reflect discussions of pregnancy and abortion decision-making and experiences during abortion processes. These n-grams also highlight consideration of changes related to *Dobbs* and the overturning of *Roe v Wade*, particularly access while living in a restrictive setting, with the emergence of related language starting from *Dobbs* leak.

Topic Modeling

Overview

Posts from the yearly sample (N=7273) were described through 55 inductively generated topics with 3 outlier topics (in the −1 outlier group, see Table 2). These topics contained between 10 and 472 words, reflecting a range of word density across topics. On the basis of a review of topic labels and representative documents, these topics reflect that the analyzed posts described a wide range of abortion-related experiences and concerns—summarized through topic names. These topics included *abortion decision-making timing and feelings*, which commonly included "feel," "want," "baby," "know," "pregnant," and other words. *Appointments and cost barriers* was another topic describing yearly posts, including "abortion," "help," "get," "get abortion," and "appointment" as common words. In addition, people posted about *medication abortion, physical process bleeding, and clots* using words such as "bleeding," "clots," "cramps," "took," "passed," and "blood." There were also topics such as *Aid Access shipping*, where posters used words such as "package," "customs," "tracking," "usps," and "aid access."

Document Classification Using Topics and Aggregation Into Conceptual Groups

Topics describing posts from the study year (n=55) were used to classify all posts (N=7273) into their highest-probability topic. The count and proportion of posts classified under each topic are presented in Table 2. Topics with the highest number of classified posts were *seeking access to medication abortion* (2408/7273, 33.11% of posts); *abortion decision-making, sharing stories, and seeking support* (657/7273, 9.03% of posts); and *medication abortion process, timing of pills* (328/7273, 4.51% of posts).

We aggregated these topics into 8 conceptual groups: *abortion decision-making*, *navigating access barriers*, *clinical abortion*

XSL•FO
RenderX

care, *medication abortion process*, *postabortion physical experiences*, *potential pregnancy*, and *SMA process*. On the basis of conceptual group classification counts (summed topic classification counts), *navigating access barriers* was the conceptual group with the largest number of posts (2446/7273, 33.63% of all posts), which included posts describing various experiences with challenges seeking and having an abortion. Posts focused on aspects of the *medication abortion process* were the second most common (1807/7273, 24.85%), followed by *abortion decision-making* (974/7273, 13.39%), *postabortion physical experiences* (672/7273, 9.24%), *clinical abortion care* (670/7273, 9.21%), *potential pregnancy* (550/7273, 7.56%), and *SMA process* (151/7273, 2.08%).

Composite versions of representative posts for each conceptual group are presented in Multimedia Appendix 2. Select quotes for each conceptual group are presented in this section, representing the content of posts in each group for the year overall and the comparable subperiods. Some posts in the *navigating access barriers* conceptual group described difficulty obtaining an appointment at an abortion clinic, sharing stories such as the following:

> *My boyfriend and I live in the south with our 9-month-old baby, and we just found out I'm pregnant again. We really can't afford to and aren't prepared to have another child. Abortion is illegal in our state and we live 4 hours from the nearest clinic in the nearest legal state. Do we have any other options?* [Composite quote]

Others focused on challenges in accessing medication abortion, often describing specific barriers and sometimes asking for information and resources to help them access it, as with posts such as the following:

> *My girlfriend and I are in urgent need of abortion pills. She's about 3 or 4 weeks pregnant and we want to get through this asap and for not a lot of money, preferably for a few hundred dollars or less. Can anyone provide some info and walk us through the process?* [Composite quote]

Others specifically referenced concerns or issues with abortion access related to *Roe v Wade* and the *Dobbs* decision, with narratives such as the following:

> *I think I might be pregnant and I'm really scared, especially after hearing Roe v Wade might be overturned. I'm thinking of having an abortion but I live in a state where abortion will likely become illegal right away. Does anyone know if I will still be able to get an abortion somehow? I've been trying to research online and have been seen a lot of different information. Are there any online clinics? Would it be illegal to travel to another state to go to a clinic in-person? I've heard that Colorada or Illinois might be safe options but I'm just really terrified. I just want to be sure I can access an abortion no matter what happens.* [Composite quote]

Among posts describing the *medication abortion process*, there were many asking questions about or descriptions of the use of pills to have a medication abortion. These posts sometimes included specific questions about correct timing in the use of medication abortion, sharing stories such as the following:

> *I ordered pills through AidAccess and they arrived today. I've seen online that you're supposed to wait 24 hours after you take the mifepristone to then take the misoprostol, but on the box it doesn't mention timing and the instructions are very vague. I don't want to screw this up at all so can someone clarify the timing and what exactly I should do?* [Composite quote]

People also commonly posted about *abortion decision-making*. In these posts, people often described their pregnancy experiences and abortion story while seeking community support, with narratives such as the following:

> *Can anyone share about their experiences during and after their abortions around 6 weeks? I'm trying to pick between medication or surgical. My last abortion was surgical and it was not a great experience. I just want this to be over with because ideally, I wouldn't want to have to go through this, but I am not in a place to support a child financially.* [Composite quote]

Posters also wrote about making their abortion decision in relation to their relationship dynamics, with narratives such as the following:

> *I can't take this anymore, I'm going to get an abortion. I'm just not ready to have a baby and I know that this will be for the best. I'm not looking forward to having to face my partner after this. I'm afraid he's going to hate me for having an abortion and break up with me.* [Composite quote]

Posts asking questions about and describing *postabortion physical experiences* were also common, with posters describing experiences with bleeding or clots after their abortion and often seeking input from the community on how normal their experiences were:

> *I took my miso last night and have been bleeding for almost 12 hours now. I had cramping for the first few hours then a big flow of blood where I passed two big clots the size of small lemons. But those are the only clots I've had and I haven't been bleeding any more. I know you're supposed to pass a lot of clots based on what I've been reading. Should I be worried?* [Composite quote]

Posts also described aspects of *clinical abortion care*, including specific facets of clinical care—particularly ultrasound—and fears and concerns about having an abortion. Posts also focused on *potential pregnancy*, sometimes describing sexual experience and possible risk of pregnancy. In contrast, others focused on potential pregnancy after an abortion in relation to still testing positive weeks later. In addition, some posts described *experiences with SMA*, often focused on the process of ordering medication and having it shipped while asking for support from the community in navigating those processes.

RenderX

Assessing Changes in Conceptual Group Frequency Over Time

Counts and proportions of posts in each conceptual group across study subperiods based on the highest-probability (rank 1) classification, along with comparisons of proportions, are presented in Figure 3, with additional information in Multimedia Appendix 2. Overall, the number of posts to r/abortion increased after *Dobbs*. The proportion of posts related to *abortion decision-making* changed significantly across study periods (*P*=.002); with 974 posts in this group, 33% were from before the *Dobbs* leak (n=321); 13% from *Dobbs* leak to decision (n=129); and 54% after the *Dobbs* decision (n=524). In addition, while posts related to SMA were the least common, the proportion of posts in this group also changed significantly across study subperiods (*P*<.001), with 151 posts in this group, 13% were from before the *Dobbs* leak (n=20), 12% from *Dobbs* leak to decision (n=18), and 75% after the *Dobbs* decision (n=113). Changes across the study subperiods were not significant for other conceptual groups: *navigating access barriers* (*P*=.60), *medication abortion process* (*P*=.13), *post-abortion physical experiences* (*P*=.85), *clinical abortion care* (*P*=.19), *potential pregnancy* (*P*=.80).

Figure 3. Bar graph showing the proportion of r/abortion posts in each conceptual group (7 in total) in each study subperiod—before the Dobbs leak, Dobbs leak to decision, and after the Dobbs leak. The largest proportion of posts was in the navigating access barriers conceptual group, followed by medication abortion process and abortion decision-making. The proportion of posts about abortion decision-making changed significantly across subperiods, decreasing over time. Posts about self-managed abortion were the least common, but the proportion also changed across subperiods—increasing over time (N=7270 posts). *Indicates that the proportion of posts for this conceptual group varied significantly across study subperiods based on a Pearson chi-square test.

Discussion

Principal Findings

Given the rapidly changing landscape of abortion policy and access in 2022, with uncertainty and increasingly constrained pathways to care, online resources play a key role in providing access to abortion information, support, and services. Online communities in particular provide unique support for members of the public, as well as opportunities for researchers to understand emerging concerns and experiences of populations that may be hard to study through other methods [57-59]. We sought to contribute to the body of research that uses online information and leverages methods to work efficiently with large datasets to accelerate knowledge generation and provide novel insights into changing abortion-related experiences surrounding the *Dobbs* decision in 2022.

People posted on r/abortion about many different abortion-related concerns in 2022, coming to the community at various stages in their abortion trajectories. This ranged from posts seeking community input on pregnancy confirmation, abortion decision-making, pathways to access abortion, assessing abortion completion and postabortion experiences (physical and emotional), and support during and after their abortion in managing the process. Overall, the volume of posts and the breadth of content shared in them reflect that r/abortion is a community used abundantly and in alignment with its stated mission: “If you’re pregnant and don’t want to be, we can help you get an abortion. This is a proabortion, stigma-free space to ask questions, get information, and share your experiences” [82]. Given the increases in the use of r/abortion throughout 2022, this pseudonymous community may be an increasingly important online resource as abortion access continues to be restricted after *Dobbs*. Notably, other subreddits have

XSL•FO
RenderX

substantially larger volumes of community members and posts; for example, r/TwoXChromosomes had >13 million members and between 80 and 450 posts per day in 2022 compared to r/abortion with 34,000 members and between 5 and 41 posts per day [83,84]. However, r/abortion is an active and uniquely abortion-supportive community on Reddit facilitated by an active network of moderators (with the OARS), playing an important role in the landscape of abortion resources.

Overall, we observed that the conceptual group with the highest volume of posts focused on navigating barriers to abortion access, and the proportion of posts in that group did not change significantly across subperiods in 2022. This illustrates that r/abortion posters described barriers to abortion access even before *Dobbs* introduced national challenges to the legality of abortion. Previous research extensively documents pre-*Dobbs* barriers to abortion access and their adverse impacts on timely abortion access and the health of birthing people and their children; our findings illustrate the sustained influence of barriers on the experiences of r/abortion posters [10,28,29,85-101]. Posts describing navigating barriers to abortion access largely described challenges in accessing medication abortion based on topic modeling results, with some discussing the *Dobbs* decision, appointments and travel barriers, and costs. The overwhelming focus on challenges in accessing medication abortion in our sample may reflect broader trends, with use of medication abortion increasing since it became available in the United States in 2001 and now accounting for >60% of all abortions [102]. It may also reflect the unique priorities of the population using r/abortion and the potential for online resources to facilitate direct access to medication abortion. These findings are echoed and expanded by a qualitative analysis by our team using a subset of data from r/abortion following the *Dobbs* leak, which found that people described a variety of structural and social barriers to abortion access, including emerging challenges such as concerns about legal risks associated with accessing abortion. These findings also highlight the negative impacts of barriers on timely access to the desired modality of abortion care and mental health, as well as self-management of abortion out of necessity [36].

We also found that the proportion of posts related to SMA and abortion decision-making changed significantly throughout 2022. Abortion decision-making posts were more common before the *Dobbs* leak, whereas those related to self-management increased following the leak and decision. The relative decrease in posts related to decision-making may reflect shifting interests in the community when faced with increasing challenges. The increasing interest in SMA in our sample is notable, highlighting increasing interest in this abortion modality following the *Dobbs* leak and echoing other research indicating increased online interest in medication abortion and use of SMA during this time [103-105]. Taken together, these findings suggest that, as legal access to abortion is increasingly constrained, people may be focusing less on *whether* to have an abortion and more on *how* to access it under legal constraints. The rise in discussions about SMA implies that more individuals may be pursuing abortion outside formal health care systems, often due to legal, logistical, or financial barriers, raising concerns about legal risks and equitable access to preferred, supported abortion care.

In the SMA conceptual group, posts covered a range of topics related to procuring and receiving medications, including concerns about the credibility of online ordering platforms. The topics in the SMA conceptual group align with previous research describing the experiences of using online platforms (often Aid Access), highlighting concerns about scams, ordering, shipping, and potential surveillance [106]. Additional work by our team expands these findings related to SMA, highlighting the many questions posted about accessing and using medications to self-manage and critical gaps in posters' access to medical and legal information [107]. Notably, in the time since this study, the number of online platforms for ordering abortion medications has grown substantially, and abortion providers have started offering these medications legally from some states within the United States under shield laws [108]. As SMA becomes increasingly common and facilitated by more diverse pathways for obtaining medications, which is expected particularly in areas where abortion access is restricted [11,109], continued research is needed to understand emerging needs and challenges for people using online platforms to facilitate safe and satisfactory abortion experiences at home with limited clinical support. The experiences of people using the array of platforms facilitating access to medications for abortion are relatively unknown and warrant further research, particularly given likely differences in customer support and service quality across websites. In addition, efforts to protect and expand access to accurate online SMA information are critical as people rely on fully digital pathways to access services and face stigma, isolation, and legal risks that further limit access to information from nondigital sources.

This research explores abortion as a health and social concern on Reddit, with discussions influenced by the changing sociopolitical context in the United States. Previous qualitative research has explored how Reddit and r/abortion have been used for specific abortion-related concerns (eg, abortion costs and self-management barriers [28-33]), finding that analysis of Reddit data can provide meaningful insights into these concerns grounded in the unsolicited narratives shared in publicly available data. In addition, a recent study by Valdez et al [48] used NLP (specifically topic modeling with BERTopic) to describe discussions in a subset of posts to r/abortion and another Reddit community focused on abortion debate (r/AbortionDebate) and found that r/abortion was commonly used to seek and share social support, in contrast to r/AbortionDebate being used to discuss changing views on abortion. However, this analysis presents a novel approach to working with a theoretically complete sample of data from r/abortion during a period of sociopolitical changes that generated extreme uncertainty, fear, and constraint regarding abortion access in the United States. Our findings speak to the changing use of r/abortion during 2022 and the power of leveraging innovative research approaches grounded in content expertise to explore abortion as a critical public health concern.

Strengths and Limitations

There are several important limitations to keep in mind when interpreting these findings. First, while using data from an abortion subreddit leverages the power of Reddit as a pseudonymous platform known to invite discussion of sensitive

XSL•FO
RenderX

health concerns [24-26], we have no systematic demographic information about the r/abortion posters contributing to our sample. While most Reddit users across the entire platform are aged between 18 and 29 years (64%), male (64%), White individuals (70%), and based in the United States (52%) [110], research indicates that the demographics of members vary across subreddits, and in r/abortion, most users identify as female (86.1%) [111]. We also know that the population of Reddit and r/abortion users is unique [110,111] and likely does not represent people considering, seeking, and having abortions across the United States. As such, our findings cannot be interpreted as reflective of population-level experiences or concerns beyond r/abortion. Notably, in the post-*Dobbs* context, the access experiences of young people and those of a lower socioeconomic status are likely uniquely challenged as the impacts of *Dobbs* are experienced more intensely in these groups compared to others [1]. While the lack of demographic information limits our ability to determine who used r/abortion in 2022, there were stories shared in the community that represented a range of abortion experiences—including people who had not yet reached clinical abortion care, deciding between clinical abortion and SMA, and who never interacted with health care providers during their abortion processes. This representation of a diverse set of abortion experiences is a substantial contribution to our knowledge based on user-driven narratives and priorities.

Furthermore, although almost half of the users on Reddit live in the United States [20], it is a global platform. In qualitative analyses of a random subsample of these data, posts from people living outside of the United States were identified and excluded, accounting for 9% of the posts [37]. However, we took no similar steps for the current NLP analysis, introducing uncertainty about the connection of our results to the US abortion access context and policy change assuming that approximately 10% of all posts to r/abortion were from outside the United States. Despite this, we believe that US policy has a large enough impact on global perceptions of abortion access that this limitation does not substantially detract from our findings.

In addition, not all posts were correctly classified by BERTopic into topics, and perfect accuracy in classification is not expected. There are also methodological concerns related to our decision to use BERTopic model results to classify posts into a single topic as BERTopic operates under the assumption that documents can fall into multiple topics simultaneously. Choosing classification into a single topic allowed us to effectively make direct comparisons in the volume of posts per topic and conceptual group across subperiods but reduced consideration of the nuanced ways in which people talk about these topics within posts—often discussing multiple concerns that fall under different topics and perhaps different conceptual groups within 1 submission. It is plausible that this approach resulted in a substantial underestimation of the commonality of some topics within the corpus based on classification. However, in choosing to classify based on the topic with the highest probability for each post, we effectively captured the topics discussed most substantively in each submission—providing a simple and interpretable representation of the most dominant topic and related conceptual group described in each post.

Furthermore, while we attempted to be rigorous and precise in creating topic titles and aggregating topics into conceptual groups, the process was based on content expertise applied during subjective manual review guided by quantitative measures of topic similarity. Division of topics into conceptual groups was sometimes difficult, with posts in topics sometimes not exclusively describing clear concepts, underscoring concerns about using a single classification approach for each post. Delineating between topics related to medication abortion and SMA was conservative, erring on the side of only considering a topic as pertaining to SMA if it was very clearly focused on accessing, ordering, shipping, and receiving medications from an online platform. As such, this classification and aggregation approach likely underestimated the commonality of posts about SMA and perhaps the relative increase in those posts following the *Dobbs* leak and decision. This is further supported by the likelihood that people, despite the protection provided by pseudonymity on Reddit, may have limited their public sharing of information that overtly indicated that they were self-managing out of fear of prosecution [72,73].

Furthermore, the conceptualization of 3 subperiods in 2022 was based on key moments in national abortion policy but does not account for the rolling changes in abortion access within each of those periods. Even before the *Dobbs* leak, states were implementing abortion restrictions. Following the *Dobbs* decision, the enactment and enforcement of restrictions and bans across states has been progressive rather than the *Dobbs* decision functioning as a clear change point in all policies. As such, aggregating data into subperiods makes assumptions about the homogeneity of experiences of r/abortion users. Despite this concern, under the premise of exploring use of r/abortion and changes over time in the impacts of national abortion policy and related uncertainty about abortion access across states, using 3 subperiods as we did is a sound approach.

Conclusions

Our analysis provides a holistic view of the content of post submissions to r/abortion in 2022. In this research, we were able to merge content expertise and machine learning tools to describe people's posts to an online community for abortion during a time of extreme change and uncertainty in abortion access in the United States. Our findings highlight the critical role of r/abortion as an abortion-supportive resource, providing an online community for people to voice a vast array of concerns, questions, and experiences. They also illustrate how the use of r/abortion changed in 2022, speaking to the increased importance of SMA following the Dobbs leak. Overall, our findings highlight the need for further research exploring this trend across online platforms facilitating access to abortion information, support, and services—with particular focus on those providing access to abortion medications. As policies and pathways to abortion access continue to change across the United States, approaches leveraging NLP with sufficiently large samples of textual data present opportunities for timely monitoring, with the potential to reflect a broad range of abortion experiences, including those of people who have limited or no interaction with clinical abortion care.

Abstract

Background: User demographics are often hidden in social media data due to privacy concerns. However, demographic information on substance use (SU) can provide valuable insights, allowing public health policy makers to focus on specific cohorts and develop efficient prevention strategies, especially during global crises such as the COVID-19 pandemic.

Objective: This study aimed to analyze SU trends at the user level across different demographic dimensions, such as age, gender, race, and ethnicity, with a focus on the COVID-19 pandemic. The study also establishes a baseline for SU trends using social media data.

Methods: The study was conducted using large-scale English-language data from Twitter (now known as X) over a 3-year period (2019, 2020, and 2021), comprising 1.13 billion posts. Following preprocessing, the SU posts were identified using our custom-trained deep learning model (Robustly Optimized Bidirectional Encoder Representations From Transformers Pretraining Approach [RoBERTa]), which resulted in the identification of 9 million SU posts. Then, demographic attributes, such as user type, age, gender, race, and ethnicity, as well as sentiments and emotions associated with each post, were extracted via a collection of natural language processing modules. Finally, various qualitative analyses were performed to obtain insight into user behaviors based on demographics.

Results: The highest level of user participation in SU discussions was observed in 2020, with a 22.18% increase compared to 2019 and a 25.24% increase compared to 2021. Throughout the study period, male users and teenagers increasingly dominated the SU discussions across all substance types. During the COVID-19 pandemic, user participation in prescription medication discussions was notably higher among female users compared to other substance types. In addition, alcohol use increased by 80% within 2 weeks after the global pandemic declaration in 2020.

Conclusions: This study presents a large-scale, fine-grained analysis of SU on social media data, examining trends by age, gender, race, and ethnicity before, during, and after the COVID-19 pandemic. Our findings, contextualized with sociocultural and pandemic-specific factors, provide actionable insights for targeted public health interventions. This study establishes social media data (powered with artificial intelligence and natural language processing tools) as a valuable platform for real-time SU surveillance and prevention during crises.

Introduction

Overview

Substance use (SU) prevalence varies across demographics such as age, gender, race, and ethnicity. During the COVID-19 pandemic, these differences became more pronounced. The pandemic not only increased global SU, with overdose deaths rising by 29.4% [1], but also exacerbated societal and racial inequalities [2,3] and significantly impacted mental health [4-7]. As people often turn to substances as a coping mechanism during crises [8,9], the pandemic likely led to increased SU [10], particularly among populations considered vulnerable [11]. Investigating how these trends shifted across different demographic groups during the pandemic is crucial for understanding public health challenges and developing targeted interventions.

Background

Gender, Age, and Racial Disparities in SU

According to the National Center for Drug Abuse Statistics (NCDAS) [12], men are more likely than women to use illicit drugs. In 2020, 22% of male individuals and 17% of female individuals used illegal drugs or misused prescription drugs within the last year, and the highest prevalence was among individuals aged 18 to 25 (39%), followed by those aged 26 to 29 (34%) [13]. Racial and ethnic disparities have always been prevalent in the history of drug use. For instance, White individuals were more likely to misuse prescription drugs, while other races were more likely to use other illicit drugs [14]. Similarly, opioid overdose death rates were higher in Black individuals [15]. Furthermore, the disparities by race and ethnicity were also found to be varied with age. For most SU disorders, estimated prevalence was higher for White participants at younger ages and Black participants at older ages [16].

Importance of Studying SU During the COVID-19 Pandemic

Given the preexisting disparities in SU, the COVID-19 pandemic likely exacerbated these trends. According to the Centers for Disease Control and Prevention [1], COVID-19 mortality rates from January 1, 2020, to May 31, 2024, varied significantly by age, gender, race, and ethnicity. Non-Hispanic White individuals accounted for 67% of deaths, individuals aged ≥75 years represented approximately 54% of deaths, and male individuals comprised 54% of the mortality rate. Simultaneously, the COVID-19 pandemic brought significant social and economic changes, disproportionately affecting minoritized populations and those considered underprivileged [16,17]. The rapid spread of the virus overwhelmed health care services, leading to lower priority for treatment for racial and ethnic minority people and individuals considered economically disadvantaged [18,19]. This discrimination exacerbated mental health issues [4], also highlighted by the US Centers for Disease Control and Prevention [1], which noted disparities in mental health and substance misuse among racial and ethnic minority populations due to unequal access to care, psychosocial stress, and social determinants of health. Given the disparities in COVID-19 mortality rates by age, gender, race, and ethnicity and the social and economic challenges exacerbated by the pandemic, studying SU trends across different demographic groups requires high attention. The disproportionate impact on minoritized populations and those considered underprivileged highlights the need to understand how these factors influenced SU, which will aid in developing targeted public health strategies to address the specific needs of populations considered affected.

Natural Language Processing and Its Application in Health Care

The advent of advanced natural language processing (NLP) techniques, particularly deep learning models, has revolutionized the health care field, enabling researchers to extract meaningful insights from vast and complex datasets for advanced decision-making. Health care data, which include unstructured sources such as medical reports, electronic health records, clinical trials, and social media, has traditionally posed significant challenges for analysts due to its volume, variability, and complexity. Recent advancements in NLP have addressed these challenges by facilitating tasks such as health information retrieval and extraction, text summarization, sentiment and emotion analysis, and the construction of medical ontologies and knowledge graphs. For instance, studies have demonstrated the utility of NLP in analyzing social media data to monitor public health trends, such as SU and mental health discussions during crises [20]. Similarly, NLP has been applied to identify patterns in clinical texts and patient narratives, enabling personalized health care interventions and improved decision-making [21]. These applications highlight the transformative potential of NLP in health care, particularly in leveraging unstructured data to address pressing public health challenges.

Related Study

The study of SU prevalence across demographics has predominantly relied on survey-based research conducted by national agencies such as the Substance Abuse and Mental Health Services Administration (SAMHSA) [13] and the National Institute on Drug Abuse (NIDA) [22]. For example, the National Survey on Drug Use and Health (NSDUH) [12], administered by SAMHSA, provides comprehensive data on SU and mental health issues among the US population aged ≥12 years. Similarly, the Monitoring the Future [23] survey, funded by NIDA, focuses on SU patterns among youth by surveying middle and high school students (grades 8, 10, and 12). Both surveys provide detailed reports on the use of illicit and nonillicit drugs, disaggregated by age, gender, race, and ethnicity at a national level. In addition to these national surveys, various individual studies [16,24] have also explored SU disparities across demographics such as age, gender, race, and ethnicity.

While these surveys offer valuable insights, their scope is often limited by the diversity of true populations and the duration of the studied period. Traditional survey methods often rely on self-reported data, which can be affected by social desirability bias and recall errors. In addition, surveys are typically conducted annually or biennially, providing only periodic snapshots of SU trends. Moreover, the COVID-19 pandemic

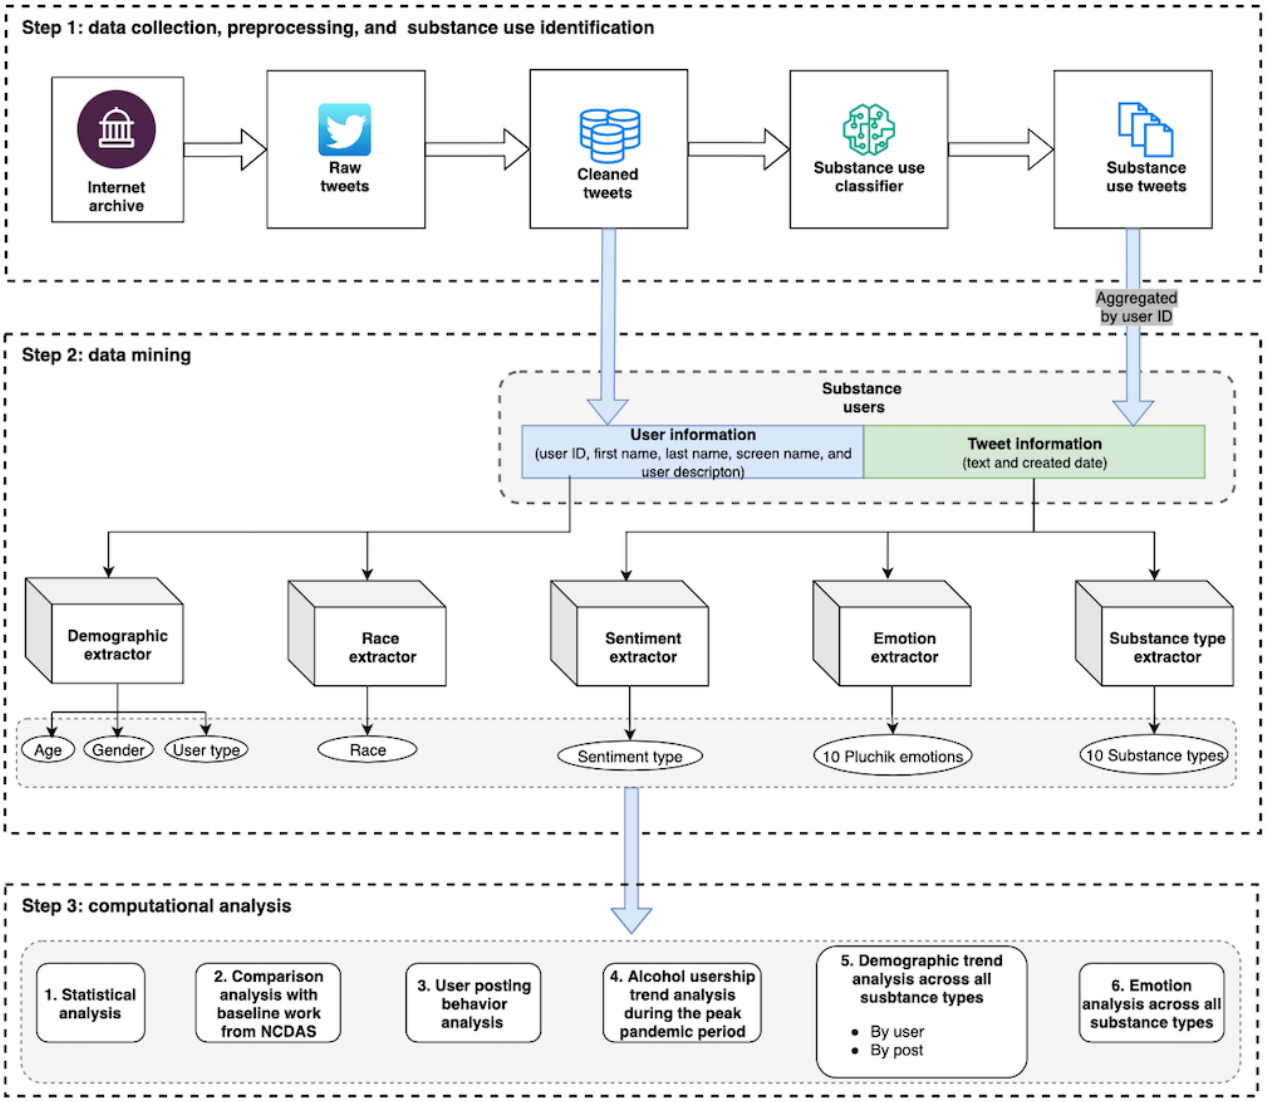
XSL•FO
RenderX

posed additional challenges for data collection; for example, SAMHSA 2020 was only able to collect data for the first and fourth quarters due to restrictions on in-person activities [13].

In contrast, social media data addresses many of these limitations. Social media platforms capture real-time, user-generated content that often reflects more authentic behaviors and sentiments. In addition to this, researchers have also shown the prevalence of SU discussions on social media [25-32], possibly due to its anonymity feature. Likewise, the continuous stream of data allows researchers [26,28,33-35] to monitor trends as they evolve, providing insights that are not possible with traditional survey methods. In addition, the vast amount of data available on social media enables a more detailed analysis across a large population [34], including those that might be underrepresented in surveys [32,36].

Despite the extensive research on SU trends, there remains a gap in understanding how these trends vary across different demographic groups, especially in the context of the COVID-19 pandemic. Existing studies have primarily relied on less diverse survey data or short-term real-time data, often overlooking the dynamic and nuanced shifts in SU behavior during global crises. This study aimed to address this gap by leveraging a large-scale social media dataset to provide a more granular and continuous analysis of SU trends across diverse demographics before, during, and after the pandemic. The following research questions (RQs) are designed to explore these trends in detail, offering insights into how age, gender, race, ethnicity, and emotional factors have influenced SU patterns during the study period:

1. What are the statistical distributions of overall SU posts and their users, categorized by key demographic variables in prepandemic, pandemic, and postpandemic periods?
2. To what extent do the SU patterns and demographic distributions observed in Twitter (now known as X) discourse from 2019 to 2021 correspond with or differ from the baseline trends reported by the NCDAS and other research?
3. What are the temporal trends in SU posts across different substance types throughout the study period, and how does the frequency of user posting behavior vary over time for each substance type?
4. How did the number of individuals discussing alcohol change within the first 2 weeks following the pandemic declaration compared to other users, and what short-term trends in user behavior emerged across different age groups, genders, races, and sentiments during this period?
5. What are the trends in user participation across different demographics for each substance type?
6. What emotional expressions are prevalent across all substance types?



Methods

Overview

This study extends our previous research [37], which developed and validated a SU classifier using Robustly Optimized Bidirectional Encoder Representations From Transformers Pretraining Approach (RoBERTa) model [38] to identify SU posts from a cleaned dataset of 1.13 billion English-language posts (2019-2021). While our previous research [37] focused on analyzing SU at the post level, this study focuses on the user level. Thus, the key task of this study is to formulate the user base of SU posts from the previous study, followed by data mining (step 2) and computational analysis (step 3). As illustrated in Figure 1, step 1 encompasses the data collection, preprocessing, and SU identification modules. Step 2 involves user base formation and data mining methods for extracting demographic and emotional information associated with users and posts. Finally, step 3 involves computational analysis of the extracted data for users across various dimensions.

Figure 1. Methodology of the study design. NCDAS: National Center for Drug Abuse Statistics.

Data Collection, Preprocessing, and SU Identification

We downloaded the raw tweet data from the Internet Archive [39], covering the period from January 2019 to December 2021. Unlike our previous study, which extracted only tweet information, this study also retrieved user information necessary for user-level analysis. Thus, the downloaded tweets had 2 types of information: tweet information and user information. The text information comprises text and the created date of a tweet, while user information comprises user ID, screen name, first name, last name, and user description.

The data processing of tweets was carried out in multiple steps. Initially, we filtered out all non-US tweets and duplicate or retweeted tweets to focus our research on English-language tweets and reduce redundancy, respectively. Then, we cleaned the text data by removing punctuation and stop words using the Natural Language Toolkit package and converted all characters to lowercase to maintain uniformity and prevent discrepancies caused by case sensitivity. Subsequently, we also replaced all the usernames, URLs, and hashtags in the post with the keywords *USER*, *HTTPURL*, and *HASHTAG* to hide the users' identity and ease semantic understanding. Then, we performed lemmatization using the Natural Language Toolkit package to reduce words to their base form (eg, *drinking* to *drink*) to standardize text and improve consistency. Finally, we removed tweets containing <3 words, as these were deemed too brief to provide substantive insights. This comprehensive preprocessing approach resulted in a refined dataset of 1.13 billion cleaned tweets (3.1 million /1.13 billion, 26.84% in 2019; 4.5 million/1.13 billion, 40.05% in 2020; and 3.8 million/1.13 billion, 33.11% in 2021).

The cleaned tweets were then analyzed using a deep learning–based SU classifier, a pivotal element of our earlier research. This classifier was developed using a state-of-the-art model, RoBERTa [40], in conjunction with various techniques, such as transfer learning and a human-in-the-loop approach [41], to enhance its performance, achieving an accuracy rate of 80%. The successive validation on the sample data is also presented in the study by Maharjan et al [37]. The entire workflow for data collection, preprocessing, and SU identification is depicted in step 1 of Figure 1. This comprehensive phase concluded with 2.8 million, 3.5 million, and 2.5 million SU posts identified for the years 2019, 2020, and 2021, respectively, which we used in this study.

RenderX

Data Mining

Overview

Data mining constitutes a critical initial phase for conducting this research. At first, we formulated the SU dataset by users (or user base dataset) required in this work. Subsequently, we used this user base dataset to extract additional variables, where we used 5 different analytical modules: 2 focused on demographic variables (M3-Inference [35] and Ethicolr [40]) and 3 targeted at other relevant variables (Valence Aware Dictionary and Sentiment Reasoner [VADER] [42], SpanEmo [43], and a substance type extractor developed in our previous research [37]). Specifically, M3-Inference [44] and Ethicolr [40] were used to extract demographic information, such as age, gender, user type, race, and ethnicity from the user SU dataset. Alongside, VADER [42], SpanEmo [43], and the substance type extractor [37] were used to extract sentiment, emotional content, and substance type, respectively, from the post SU dataset. In the following sections, we provide detailed descriptions of the user base dataset and each of the 5 extraction modules.

SU User Base Dataset

For this study, we considered unique users who had posted at least 1 SU-related post. If the user has never posted any SU-related posts, their posts would never be included in SU posts, and the user would not be considered a substance user. We used a metadata field called *user ID* which served as a unique identifier for all users on the Twitter platform. Technically, we used identified SU posts from step 1 and aggregated them by unique user IDs to obtain the unique user base for this study, as shown in Figure 1. For example, if we had 10 SU posts, where 3 posts belonged to user A, 2 posts to user B, and 5 posts to 5 distinct users (C, D, E, F, and G), then we aggregated these posts by unique user IDs, such that there would be 7 unique SU users—A, B, C, D, E, F, and G. This step resulted in user base datasets of 2,131,457 for 2019, 2,604,123 for 2020, and 2,553,235 for 2021. After the user dataset was formulated, we further retrieved the user metadata for each user by performing a joint operation on the aggregated user base dataset and the original cleaned dataset. Thus, the final dataset used in this study included both tweet and user information. Tweet data included the content and creation date, while user data comprised user ID, first name, last name, screen name, and other profile details. This information served as an input for successive modules to extract additional variables such as age, gender, race, sentiment, and emotion.

Demographic (Age, Gender, and User Type) Extraction Using M3-Inference

In this study, we implemented the M3-Inference model [35] to extract demographic information, specifically age group, gender, and user type, from Twitter accounts. M3-Inference is an open-source Python implementation of a multimodal deep learning system, trained on extensive datasets, including Twitter, IMDB, and Wikipedia. The model's architecture enables it to simultaneously predict 3 key demographic attributes: multimodal capabilities, which allow processing of both image and text features (we only used text features to perform our work); multilingual support, which includes 32 languages; and multiattribute prediction, which facilitates simultaneous forecasting of age, gender, and user type.

In terms of classification, the model treats gender (female or male) and user type (human or organization) as binary classification tasks, while age is categorized into 4 distinct groups: ≤18, 19 to 29, 30 to 39, and ≥40 years. For our analysis, we used a text-only pipeline to derive demographic predictions. This pipeline involved generating character-based embeddings for each textual input (username, screen name, and biography) and passing them through a 2-layer bidirectional character-level long short-term memory network.

To validate the M3-Inference model's efficacy in predicting demographic attributes, we collected profile information from 50 known Twitter users (as detailed in Table S1 in Multimedia Appendix 1). For the age classification, we combined the 19 to 29, 30 to 39, and ≥40 years age groups into a single nonteenager category, thereby reformulating the age prediction as a binary classification task. The model's performance metrics on the collected validation data indicated an accuracy of 99.05% for user type, 95% for gender, and 89% for age classification, with corresponding F_1-scores of 0.98, 0.94, and 0.73, respectively.

Race and Ethnicity Extraction Using Ethnicolr

To infer the racial and ethnic backgrounds of individuals from their names, we used the Ethnicolr Python library [40]. This tool leverages several models based on different datasets, including US census data, Wikipedia entries, and Florida voter registration records, to predict the likelihood of an individual's race and ethnicity. The model has 3 models depending on the type of dataset it is trained on. In our case, we used the Census Last Name Model, which was trained on US census data [45] from the years 2000 and 2010. This model estimates the percentage likelihood that an individual belongs to 4 main racial and ethnic categories, such as White, Black, Asian or Pacific Islander, or Hispanic. The predictions are appended as additional columns in the dataset, providing a probabilistic breakdown of racial composition. We verified the model on our sample data, where the model achieved an accuracy of 90%. The sample-predicted data are presented in Table S2 in Multimedia Appendix 1. However, in our study, we were able to extract the race information for only those posts that had the first name and last name present in the tweets; otherwise, the identification was not accomplished. Hence, approximately 65% (4.3 million/6.6 million) of the total users were identified, as detailed in Table S6 in Multimedia Appendix 1.

Sentiment Extraction Using VADER

VADER [42] is an open-source sentiment analysis tool designed specifically for analyzing social media text. It combines a lexicon-based approach with contextual rules to determine the sentiment of text as positive, negative, or neutral. VADER's lexicon assigns sentiment scores to words on a scale from −4 (very negative) to +4 (very positive). Contextual adjustments are made through several mechanisms; punctuation, such as exclamation points, can amplify sentiments; capitalization highlights intensity, with all-caps being more emphatic; degree modifiers, such as "very," strengthen sentiment; and

XSL•FO
RenderX

conjunctions, such as "but," can alter sentiment direction. The tool calculates a compound score, ranging from −1 (very negative) to +1 (very positive), by summing these adjusted scores. This method enables VADER to effectively capture both explicit and nuanced emotional expressions, providing a quick and reliable measure of overall sentiment in large volumes of text. The predicted sentiments for sample tweets are presented in Table S3 in Multimedia Appendix 1.

Emotion Extraction Using SpanEmo

SpanEmo [43] is a deep learning–based multilabel emotion recognition model. It analyzes text segments (spans) and classifies each span according to the emotions it conveys. The keywords associated with each emotion class are presented in Table S4 in Multimedia Appendix 1. This is particularly useful in complex texts where different parts may express different emotions. The tool uses NLP techniques to understand the context and semantic meanings of words and phrases, which allows it to accurately detect emotions even in nuanced or mixed emotional content. The model is based on bidirectional encoder representations from transformers, which takes the number of emotion classes (|C|=10) and a sequence "s" as inputs formatted with standard tokens (start_of_token [CLS] and separator_token [SEP]) as [CLS] + [C] + [SEP] + s. The encoding of emotion classed in the input makes the model learn the association between the emotion classes and the words in the input sentence, which is why it outperforms existing emotion classifiers. The model outputs 10 multiemotion classes, namely, anger, anticipation, disgust, fear, joy, love, optimism, pessimism, sadness, surprise, and trust. Before using this module, we finetuned this model on the SemEval-2018 multilabel emotion classification dataset [45] and achieved a F_1-micro score of 0.70. The predicted emotions for sample tweets are presented in Table S5 in Multimedia Appendix 1.

Substance Type Identification

The substance type identification module is also based on our previous research [37]. In previous research [37], we considered the 10 primary substance types categorized together based on their pharmacological and behavioral effects and used the list of keywords from NIDA [22] to formulate keyword-based identification. The 10 types of substances were tobacco, alcohol, cannabinoids, opioids, stimulants, club drugs, hallucinogens, dissociative drugs, prescription medications, and other compounds.

Theme Identification

In this study, we used 6 key themes that we formulated in our previous study [37]. The 6 key themes were COVID-19, economic factors, social influences, mental health, supply chain disruptions, and health care disruptions. The themes were formulated using latent Dirichlet allocation token analysis and were based on significant COVID-19 factors, such as stress and concerns related to COVID-19, economic instability, social dynamics, mental health issues, and disruptions in drug supply and health care services.

Computational Analysis

In this study, we used 2 primary statistical techniques: trend and comparison analysis, along with sentiment and emotion analysis.

Trend and Comparison Analysis

To explore temporal patterns in SU discussions, we conducted a trend analysis, examining the frequency of posts over time. This allowed us to compare SU trends before, during, and after the pandemic. We further performed comparative analysis to assess differences in SU discussions across demographic categories, including age, gender, and race, identifying key disparities and dominant trends.

Sentiment and Emotion Analysis

We applied the VADER model to perform sentiment analysis, classifying the overall tone of posts (positive, negative, or neutral) related to SU. In addition, the SpanEmo model was used for emotion detection, allowing us to identify and categorize emotional expressions (eg, joy, anger, and sadness) linked to specific substances.

These methods provided insight into both the temporal dynamics of SU discussions and the emotional context in which they occurred.

Ethical Considerations

To ensure the privacy and confidentiality of individuals whose data were analyzed, all study data underwent a rigorous deidentification process before analysis. The data for this study were sourced from publicly available platforms [39], containing no identifiable personal information. In addition, the sample posts were preprocessed to transform them into tokens, effectively obscuring any details that could reveal users' identities. Our research was supported by the SAMHSA Strategic Prevention Framework-19 (grant 6H79SP081502), which was approved by the institutional review board at Kent State University (IRB20-182).

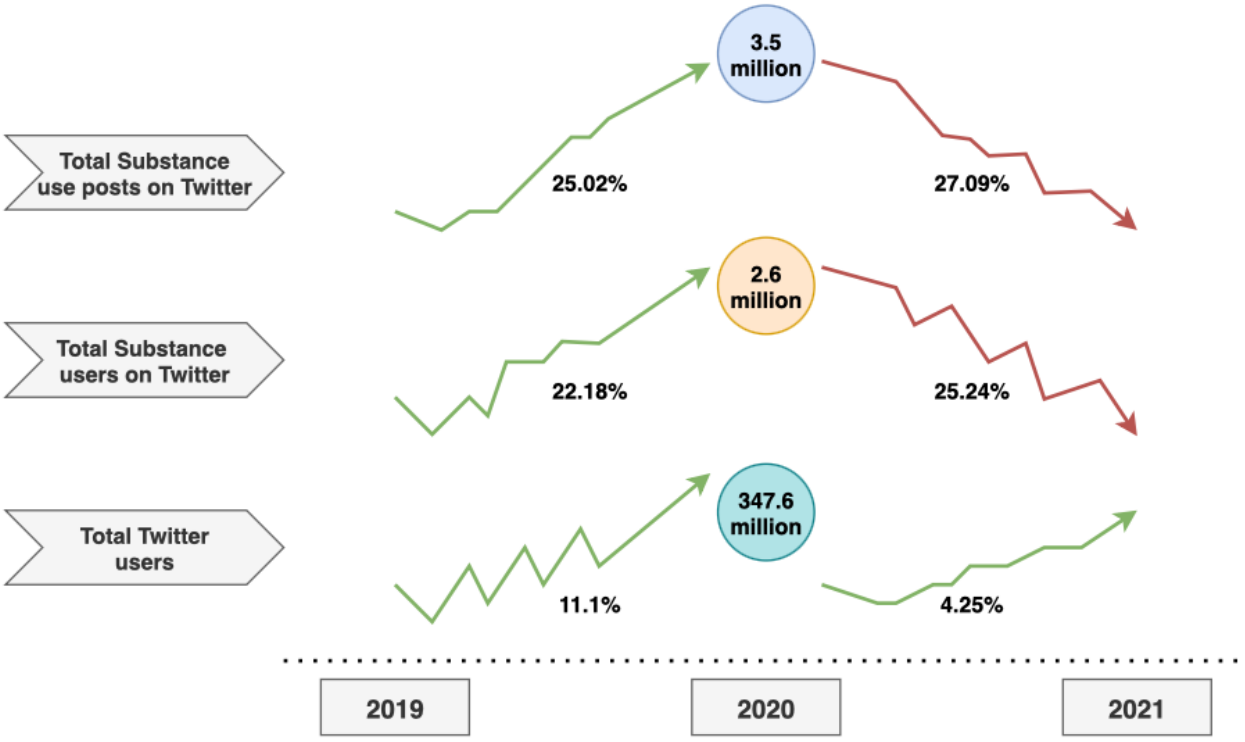
Results

Overview

In this study, we present a fine-grained demographic analysis of SU discourse on Twitter from a dual perspective: by post and by user. After preprocessing and identifying SU-related content, our final dataset included 2,799,726; 3,502,171; and 2,553,235 posts and 2,131,457; 2,604,123; and 1,946,742 users in 2019, 2020, and 2021, respectively. In the following sections, we first present a substantial summary of SU trends across all demographic dimensions: user type, gender, age group, race and ethnicity, and sentiment. Then, we compare our results with survey-based baseline research from NCDAS. Furthermore, we analyze the user trends on different substances, where alcohol users were found to be the prime users during the peak pandemic (March 2020 to June 2020) period. Hence, we performed a detailed analysis of alcohol users and posts during this time. In addition to this, we present the trends of all SU by users across 5 dimensions for each substance type. Finally, we present radar

XSL•FO
RenderX

plots to understand the associated emotions with each substance type.



RQ 1: What Are the Statistical Distributions of Overall SU Posts and Their Users, Categorized by Key Demographic Variables in Prepandemic, Pandemic, and Postpandemic Periods?

Our key findings from the statistical analysis are presented in Table S6 in Multimedia Appendix 1, which summarizes the distribution of identified SU posts by both posts and users, further segmented by various categories, including user type, gender, age group, sentiment, race, and ethnicity. The Twitter user base has been expanding annually, with increases of 11.1% in 2020 and 4.25% in 2021 [46]. This growth is contextualized in Figure 2, where we illustrate the trends in the Twitter user base and SU in 2020, comparing both posts and users to prepandemic and postpandemic years. Notably, despite the increase in Twitter users, the marginal decline in SU posts and users in 2021 implies that SU was significantly higher in 2020.

Figure 3 presents the line plots depicting SU among the Twitter user base, categorized by gender, age group, race, and ethnicity. Statistics from Twitter users by gender [46] revealed that male users consistently outnumber female users on Twitter, with a distribution of 68% male users and 32% female users in 2020. In contrast, our analysis indicates that among substance users in 2020, 52% were male users and 48% were female users. This suggests that, despite a smaller female user base, female substance users represent a significant proportion of the overall female demographic on Twitter. As shown in Figure 3 (by gender), SU among female users increased from 2019 to 2021, whereas male users showed a declining trend over the same period.

Similarly, according to statistics from Twitter users [46], the highest levels of user engagement are found in the age group of 18 to 35 years. Moreover, our analysis also revealed a similar trend in substance users, as shown in Figure 3 (by age group), where a greater number of younger users were identified as substance users. Notably, our analysis indicated an increasing trend in SU among teenagers (≤18 years), alongside a decline among individuals aged 19 to 29 years. Our analysis identified race and ethnicity for 64.71% (1,811,516/2,131,457) of users in 2019, 64.99% (2,275,943/2,604,123) in 2020, and 66.51% (1,723,470/1,946,742) in 2021, representing approximately two-thirds of the total user base. Among these identified users, White individuals were the most prevalent across all years, as shown in Figure 3 (by race and ethnicity). The potential reasons and mitigation techniques are further discussed in the Limitations section. In addition to this, the sentiment distribution of SU posts revealed that the posts during 2019 and 2020 were highly associated with negative comments compared to 2021, as shown in Figure 4. Nevertheless, the increasing trend in positive and neutral comments after the pandemic suggests that 2020 was marked by relatively higher negative influences on SU.

RQ 2: To What Extent Do the SU Patterns and Demographic Distributions Observed in Twitter (Now Known as X) Discourse From 2019 to 2021 Correspond With or Differ From the Baseline Trends Reported by the NCDAS and Other Research?

Overview

To evaluate the extent to which the SU patterns and demographics observed in Twitter discourse align with or deviate from baseline trends reported by NCDAS, we conducted a comparative analysis of both datasets. The NCDAS provides comprehensive annual reports on SU across various demographics, which serve as a benchmark for understanding broader trends. Our analysis focuses on comparing these established trends with the data extracted from Twitter posts spanning 2019 to 2021. This comparison aims to identify consistencies or discrepancies in SU trends and demographic patterns between the 2 sources.

Key Findings From Twitter Discourse

The user distribution identified substance types and highlighted cannabinoids, stimulants, and opioids as the top 3 illicit substances discussed on Twitter (Figure 5). Demographically, male users dominated all substance types in all studied periods (Figure 6). Across the age group, SU was observed to be highest in teenagers aged ≤18 years (Figure 7). User participation in cannabinoid discussions remained the highest among all substance types, though it showed a declining trend among both adults and teenagers. Teenagers (aged ≤18 years) showed declines of 0.29% and 0.07% from 2019 to 2020 and 2020 to 2021, respectively, while adults (aged >18 years) showed declines of 0.52% and 0.07% over the same periods. For both opioids and stimulants, adults aged ≥40 years were observed to be highly involved among all age groups in all studied periods. Teenagers (aged ≤18 years) showed a decline in opioid use from 2019 to 2021. Similarly, the effect of the COVID-19 lockdown was evidenced in alcohol users profoundly (also supported by biweekly distribution charts in RQ 3; Figure 9), which increased by 80% in just 2 weeks after the global pandemic was declared on March 15, 2020.

RenderX

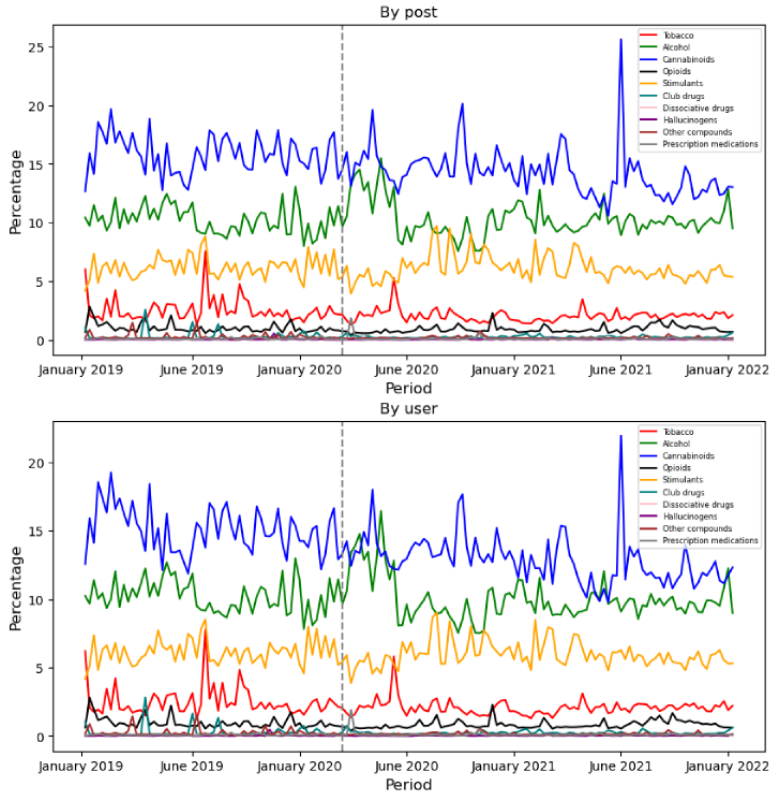
Comparison With NCDAS Trends

Both the reports from NCDAS and our analysis have highlighted cannabinoids and stimulants as the top 2 illicit drugs in the study period. While these alignments suggest convergent validity, we note that Twitter discourse reflects both personal experiences and public commentary, whereas NCDAS measures self-reported use through standardized surveys. Although opioid-related usership on Twitter did not rank among the top substance discussions, as reported in NCDAS [12], both our study and the SAMHSA 2020 report [13] showed a declining trend. From 2019 to 2020, opioid mentions declined by 8.1% in the SAMHSA report and by 25% in our study. This difference in magnitude may reflect Twitter's real-time sensitivity to news events versus surveys' annualized behavioral data. Our result shows that opioid use was mostly prevalent in adults (aged >30 years) compared to teenagers (aged <18 years). This is likely supported by the overdose deaths report [22], where 75% of overdose deaths in adults were from opioids. Likewise, club drugs are widely known to be more commonly used by young people in higher-income settings. The same can be seen in this study, where teenagers were observed to be highly involved compared to other age groups. A similar trend of SU in terms of gender was observed in both studies. Male users were actively involved in all substance types, except for a few. The exception was prescription medication, which showed a higher prevalence among female users in both studies as shown in Table 1.

Table 1. User demographics in 2020.

Drug	By gender, (n=2,604,123), n (%)		By age group (y), (n=2,604,123), n (%)	
	Female users	Male users	≤18 years	>18 years
Cannabinoids	160,668 (6.17)	192,436 (7.39)	145,801 (5.6)	207,303 (7.96)
Alcohol	111,308 (4.27)	128,797 (4.95)	77,319 (2.97)	162,786 (6.25)
Stimulants	66,939 (2.57)	80,283 (3.08)	58,848 (2.26)	88,374 (3.39)
Tobacco	22,044 (0.85)	27,554 (1.06)	20,619 (0.79)	28,979 (1.11)
Opioids	7315 (0.28)	10,441 (0.4)	6235 (0.24)	11,521 (0.44)
Club drugs	2785 (0.11)	2805 (0.11)	1952 (0.07)	3638 (0.14)
Other compounds	2227 (0.09)	1900 (0.07)	1885 (0.07)	2242 (0.09)
Prescription medications	1751 (0.07)	1649 (0.06)	1378 (0.05)	2022 (0.08)
Dissociative drugs	618 (0.02)	657 (0.03)	480 (0.02)	795 (0.03)
Hallucinogens	260 (0.01)	348 (0.01)	252 (0.01)	356 (0.01)

Trend in Alcohol Users in 2020 From Other Survey-Based Research



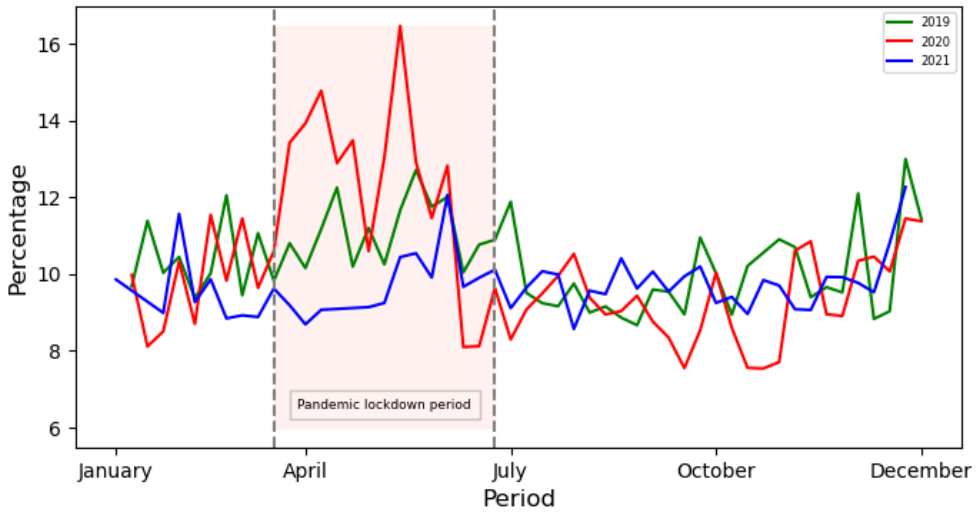
The rise in alcohol use observed in our analysis during the peak pandemic period is supported by multiple studies [45,47]. Notably, our social media data detected this surge within weeks, while surveys [45,47] reported it months later, highlighting Twitter's value for rapid monitoring, though with different population biases. A study by the United States Census Bureau [45] reported that alcohol consumption was observed to be highest as soon as college was closed during the pandemic lockdown. The study found that alcohol use was high for the users with mental health issues and low for those who received social support during the peak time; however, these patterns did not persist over time. A similar result was observed from our theme analysis detailed in RQ 4, where both social and mental health themes were observed as highly associated with alcohol posts during the peak pandemic period, March 15, 2020, to March 31, 2020. Likewise, a study by Lechner et al [48] also demonstrated that alcohol consumption was high during the peak pandemic period, which they associated with COVID-19–related stress, followed by availability of alcohol and boredom.

RQ 3: What Are the Temporal Trends in SU Posts Across Different Substance Types Throughout the Study Period, and How Does the Frequency of User Posting Behavior Vary Over Time for Each Substance Type?

The temporal trend analysis gives the nuance of change of proportions with respect to time. In our study, we plotted weekly trends for all substance types for both users and posts (Figure 8). First, we identified substance type for each post using our keyword-based methods, as detailed in our previous research [37]. Moreover, to further analyze user posting behavior, we aggregated posts by unique users. Our analysis covers the period from 2019 to 2021 and presents data on a weekly basis, capturing both short-term fluctuations and long-term trends. The plot highlights cannabinoids as the most constantly discussed substance among all, followed by alcohol, stimulants, tobacco, and others. While the cannabinoid posts were the most frequent across all study periods, the alcohol users' proportion increased sharply after the pandemic declaration day (March 15, 2020; as shown after the dotted gray line in Figure 8), demanding a detailed focus. Therefore, we present a detailed analysis of alcohol users during this period in our next question.

XSL•FO
RenderX

Figure 8. Weekly distribution across all substance types at the post and user level.



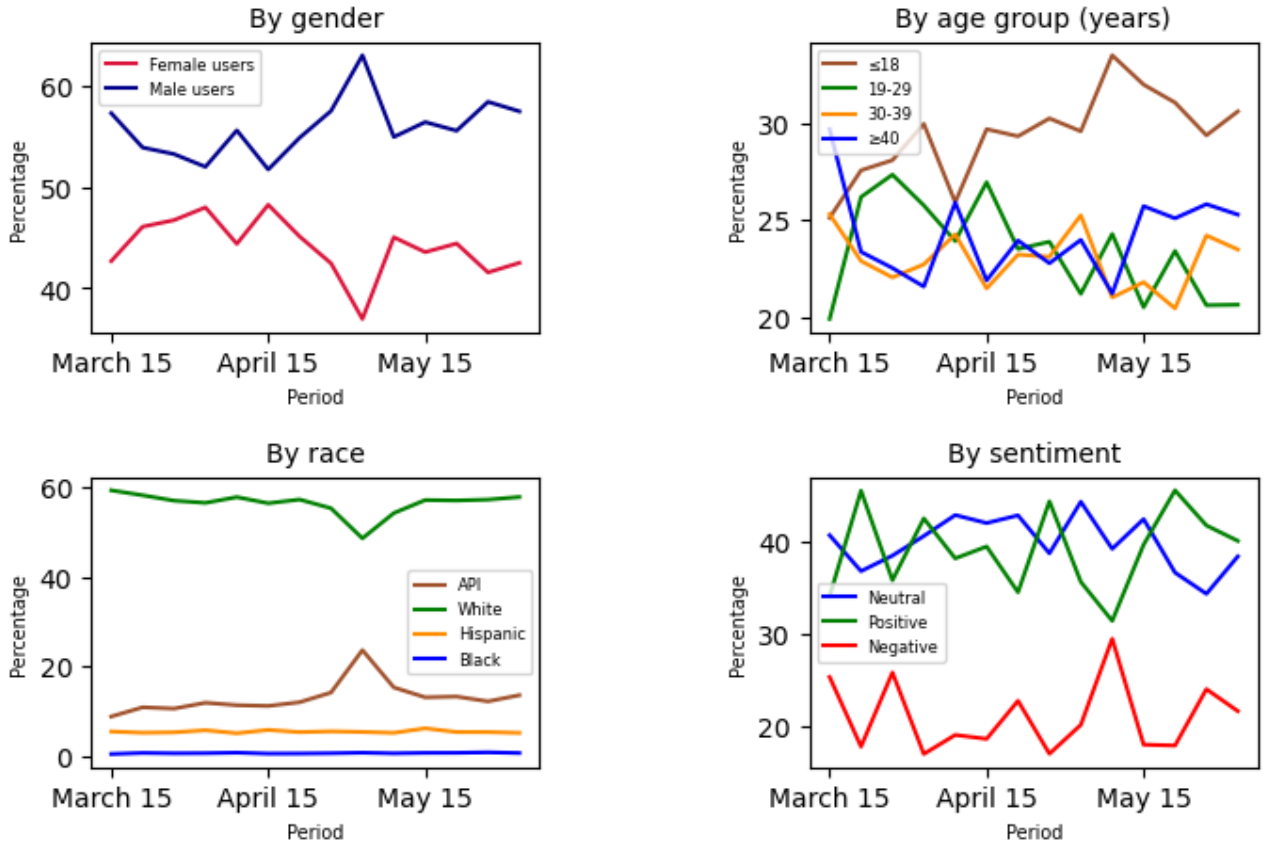
RQ 4: How Did the Number of Individuals Discussing Alcohol Change Within the First 2 Weeks Following the Pandemic Declaration Compared to Other Users, and What Short-Term Trends in User Behavior Emerged Across Different Age Groups, Genders, Races, and Sentiments During This Period?

Trend Analysis on Alcohol Users During the Peak Pandemic Period

Our weekly trend analysis from RQ 3 highlighted that after the pandemic declaration, alcohol users surpassed all other substance users, including cannabinoid users (which was the highest discussed substance throughout the study period). Hence, we drill down on the alcohol users to understand if the increase in trend is associated with COVID-19.

First, we compared weekly user trends during the pandemic year with the preceding year (2019) and following year (2021), as shown in Figure 9. The highlighted period from March 15 to June 15 marks the “pandemic lockdown period.” The visualization shows a dramatic increase in alcohol-related users during the pandemic year, while proportions in other periods remained consistent with the preceding and following years.

Figure 9. Alcohol: weekly user distribution in 2019, 2020, and 2021.



XSL•FO
RenderX

Demographic Trends on Alcohol Users During the Peak Pandemic Period

To further analyze patterns among alcohol users, we examined the pandemic lockdown period (from March 15, 2020, to June 15, 2020) in a weekly manner, segmented by age group, gender, race, and sentiment, as shown in Figure 10. Each subplot allows a comparative analysis within these specific demographic or sentiment groups. The gender and age analysis during this period show that male users and teenagers aged ≤18 years) were more involved in alcohol discussions compared to female users and other age groups, respectively. Likewise, increasing trends were observed among male users and teenagers, as well as among White users in the race analysis. However, the sentiments during this period were mostly neutral and positive.

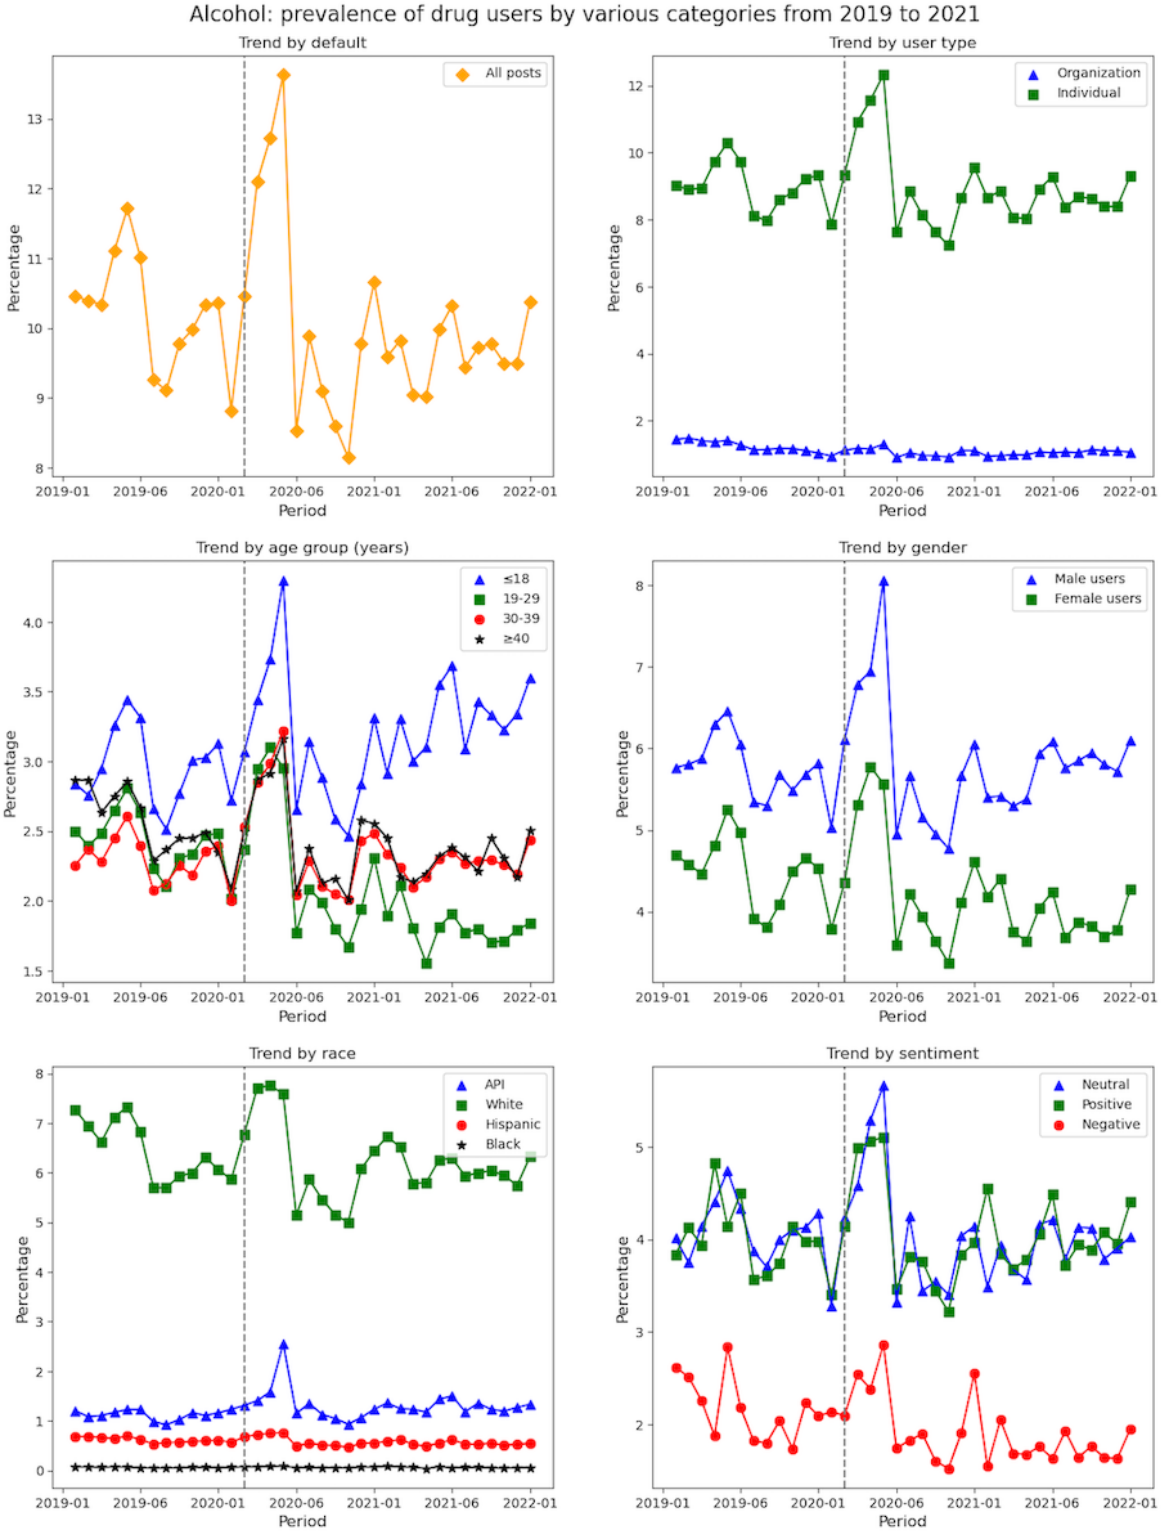
Figure 10. User distribution during the peak pandemic lockdown period (March 15, 2020, to June 15, 2020). API: Asian or Pacific islander; neg: negative; neu: neutral; pos: positive.

Posts' Content (Theme and Topic) Analysis on Alcohol Use During the Peak Pandemic Period

We performed a detailed analysis on the content of posts, where we derived the underlying themes (COVID-19, economic, social, mental health, supply disruption, and medical disruption) associated with the posts using a keyword method from our previous research [37]. The weekly distribution of alcohol posts in each theme is presented in Table 2. The distribution showed that alcohol-related discussions on peaked during the second week of March (March 15, 2020) across all themes, except the economic theme. Further analysis showed a significant increase in alcohol-related discussions during the week of March 15, 2020, particularly within the themes of social impact, mental health, supply disruption, and medical disruption.

XSL•FO
RenderX

Table 2. Weekly distribution of alcohol-related posts across all themes from February 2020 to May 2020.



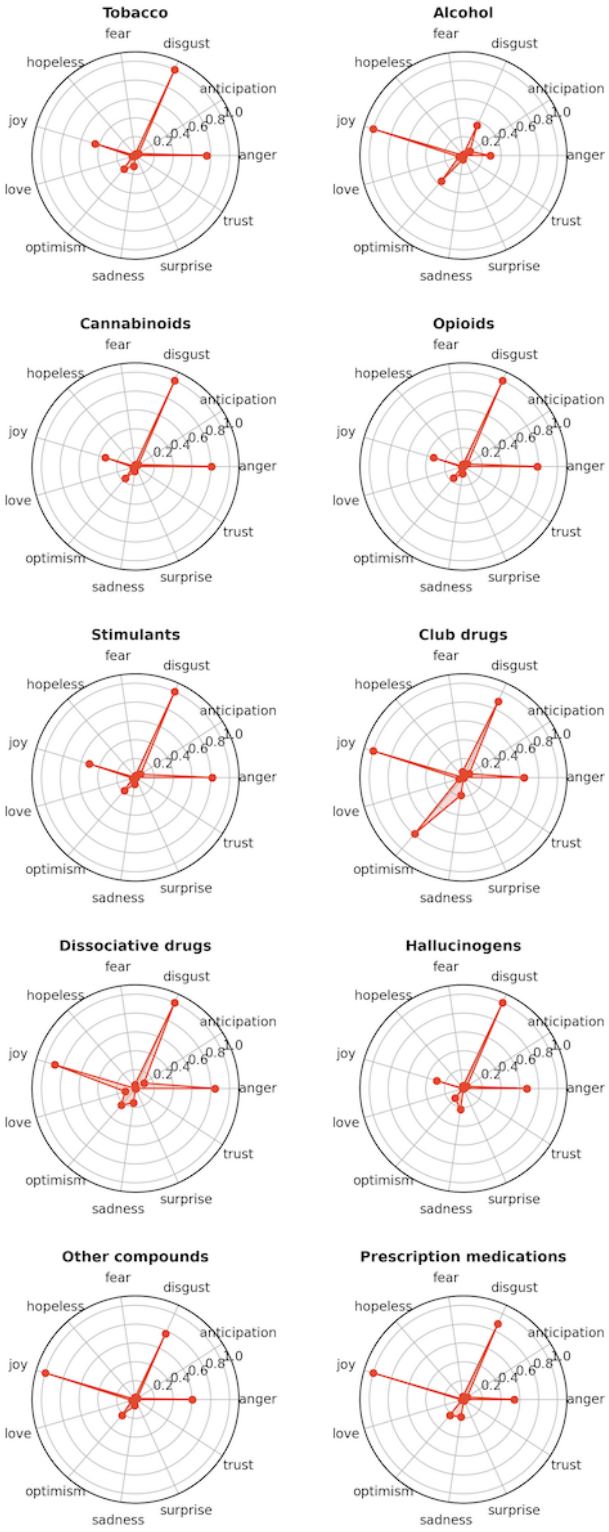
Week	COVID-19, n (%)	Economic, n (%)	Social, n (%)	Mental health, n (%)	Supply distribution, n (%)	Medical disruption, n (%)
February 1, 2020 (n=6635)	95 (1.45)	120 (1.81)	43 (0.65)	48 (0.72)	189 (2.85)	20 (0.3)
February 15, 2020 (n=5383)	81 (1.5)	73 (1.31)	38 (0.71)	35 (0.65)	153 (2.84)	17 (0.32)
March 1, 2020 (n=12,863)	1434 (11.15)	606 (4.71)	245 (1.9)	157 (1.22)	374 (2.91)	41 (0.32)
March 15, 2020 (n=26,550)	3213 (12.1)	427 (1.61)	2275 (8.57)	1226 (4.62)	1966 (7.4)	1091 (4.11)
April 1, 2020 (n=20,772)	1105 (5.32)	323 (1.55)	706 (3.4)	219 (1.05)	789 (3.8)	131 (0.63)
April 15, 2020 (n=21,027)	1022 (4.86)	389 (1.85)	871 (4.14)	198 (0.94)	787 (3.74)	97 (0.46)
May 1, 2020 (n=20,571)	2151 (10.46)	593 (2.88)	795 (3.86)	202 (0.98)	1145 (5.57)	106 (0.52)
May 15, 2020 (n=18,128)	505 (2.79)	293 (1.62)	286 (1.58)	132 (0.73)	654 (3.61)	82 (0.45)

RQ 5: What Are the Trends in User Participation Across Different Demographics for Each Substance Type?

The monthly trend diagram shown in Figure 11 provides the nuance of user trend in alcohol use by 6 dimensions, namely, overall (or by default), user type, age group, gender, race, and sentiment. The trend for other substance types can be found in Figures S2-S10 in Multimedia Appendix 1. Similarly, the trends of SU (by posts) across 6 dimensions can be found in Figures S11-S20 in Multimedia Appendix 1.

XSL•FO
RenderX

Figure 11. Alcohol users' distribution across 6 categories from 2019 to 2021. API: Asian or Pacific islander.



RQ 6: What Emotional Expressions Are Prevalent Across All Substance Types?

We applied the SpanEmo [35] model to perform emotion detection based on Plutchik Emotion Theory [36], which includes 10 main emotion categories (ie, "anger," "anticipation," "disgust," "fear," "hopeless," "joy," "love," "optimism," "sadness," "surprise," and "trust"). The detected emotions were processed further to calculate the mean intensity scores, which are presented in the radar plot in Figure 12. In our results, we present emotions for each substance type. Our results showed that SU-related discussions most frequently expressed emotions of joy, disgust, and anger.

XSL•FO
RenderX

Figure 12. Plutchik emotion analysis across all substance types.

Discussion

Principal Findings

This study established a foundation for analyzing SU across different demographics using web data, with a particular focus on the COVID-19 pandemic year. In addition to the substantial findings as a result, we made a comprehensive comparison with existing survey-based reports from NCDAS and other research works. Successively, our work has found a notable alignment with survey-based reports, as discussed in RQ 2. Notably, users' involvement in SU-related discussions surged in 2020, with users increasing by 22.18% compared to 2019 and 25.24% compared to 2021. Demographically, male users overtook female users in discussions, with their share of posts increasing from 48.87% before the pandemic to 53.4% after the pandemic. The youngest age group (aged ≤18 years) remained the most active, with their proportion growing over time, from 39.56%

XSL•FO
RenderX

in 2019 to 41.72% in 2021. Among posts with identified racial and ethnic data (64.7%-66.5% of total posts), White users predominated; however, this likely reflects platform demographics and limitations in inference methods rather than actual population distributions.

Each year, cannabinoids, alcohol, stimulants, and tobacco were the most frequently discussed substances (in ascending order), while dissociative drugs and hallucinogens were the least discussed. An overall annual decline was observed across all top substances, except for opioids, which showed a 20% drop only in 2020. A demographic breakdown for 2020 revealed that adults (aged >18 years) and male users dominated discussions on most substances. However, prescription medications and other compounds (edible substances) were more commonly discussed by female users, while tobacco use was more prevalent among teenagers (aged ≤18 years).

An increase in alcohol users was observed following the global pandemic declaration. In just a 2-week period, the alcohol users grew by 80%. Most male teenagers (aged ≤18 years) were involved in alcohol discourse, which is also supported by 2 studies [45,48]. Both studies highlighted that alcohol consumption increased during the peak pandemic lockdown period, driven by factors such as mental health challenges, social isolation, COVID-19–related stress, boredom, and easy availability. These findings are supported by our thematic analysis of alcohol-related discussions.

Another remarkable pattern was observed in the discussion of prescription medication, where female users were more involved in social media discourse. This finding is supported by Peteet et al [28], who reported that female users are more likely to use prescription medication compared to other recreational drugs.

Furthermore, our emotion analysis revealed that alcohol was the only substance strongly associated with the emotion of joy, while all other substances were mostly linked to emotions of disgust and anger. This suggests that alcohol use may be driven by positive or celebratory motives, while other substances are more often associated with negative emotional contexts.

Interpretation and Public Health Implications

Overview

This study provides critical insights into SU discourse on Twitter during the COVID-19 pandemic, revealing key demographic trends, emotional associations, and substance-specific patterns. By contextualizing these findings within sociocultural, behavioral, and pandemic-specific factors, we offer actionable strategies for public health stakeholders to design targeted interventions and policies.

Teenagers (Aged ≤18 Years): Early Exposure and Prevention

The youngest age group demonstrated the highest engagement in discussions about alcohol, tobacco, and cannabinoids. This trend may be attributed to increased screen time during lockdowns, amplified peer influence via social media, and the normalization of SU in popular culture. These findings underscore the need for age-specific prevention programs, such as school-based interventions, peer education initiatives, and social media campaigns tailored to teenagers. Addressing the accessibility of substances and providing structured recreational activities during crises are essential to reduce early exposure and experimentation.

Male Users: Gender Norms and Coping Mechanisms

Male users dominated discussions about alcohol and opioids, potentially reflecting sociocultural norms that associate SU with masculinity, as well as behavioral responses to pandemic-related stress. Men may have turned to substances as coping mechanisms due to societal expectations that discourage emotional expression and help-seeking behaviors. Male-centric messaging should emphasize healthy coping strategies and challenge harmful gender norms. Community-based programs, such as sports and recreational activities, can provide alternative outlets for stress relief and reduce reliance on substances. This aligns with NSDUH gender disparities but may be amplified by Twitter's male-skewed user base (estimated 62% male users in 2021).

Female Users: Prescription Medication Misuse

Female users were more likely to engage in discussions about prescription medications, aligning with existing research on higher rates of prescription drug misuse among women. This pattern may be influenced by higher rates of chronic pain conditions, greater likelihood of being prescribed medications, and pandemic-related stressors such as increased caregiving responsibilities. Gender-specific educational programs should address the risks of prescription drug misuse and promote alternative pain management strategies. Health care providers should be trained to recognize and address gender-specific risk factors during patient consultations.

Alcohol: Positive Perceptions and Social Coping

Alcohol was uniquely associated with the emotion of joy, suggesting it is often perceived positively and used as a social and coping mechanism. This perception may be reinforced by social media content that glamorizes alcohol consumption. Public health campaigns should reframe societal perceptions of alcohol, highlighting its negative health consequences and promoting nonalcoholic alternatives for stress relief and social interaction. Policies limiting alcohol accessibility, particularly for underage individuals, should also be considered.

Opioids and Other Substances: Distress and Self-Medication

Substances such as opioids, cannabinoids, and stimulants were linked with negative emotions, indicating that their use may be driven by distress or self-medication for underlying mental health issues. Harm reduction strategies, such as increasing access to addiction treatment services and mental health support, are critical. Integrating mental health screening into SU prevention programs can help identify individuals considered to be at risk and provide early intervention.

Leveraging Social Media for Public Health

This study highlights the potential of social media as a real-time surveillance tool for monitoring SU trends. Platforms such as Twitter can be leveraged to disseminate prevention messages, identify emerging trends, and engage populations considered

XSL•FO
RenderX

to be at risk. Policies such as stricter alcohol regulations for underage individuals and enhanced prescription drug monitoring programs can further mitigate substance misuse. Integrating mental health support into SU prevention and treatment programs is also essential, given the strong link between negative emotions and SU.

By connecting these patterns to sociocultural, behavioral, and contextual factors, this study not only advances the understanding of SU discourse during the COVID-19 pandemic but also provides a road map for public health stakeholders to design targeted interventions, policies, and campaigns. Future research should explore the integration of multiplatform data and multilingual analyses to further enhance the generalizability and applicability of these findings.

Limitations

This study builds upon our previous research [37]. As in our previous research, there is data skewness in certain months due to missing data in the original source [39]. This could potentially deviate from the actual results. Likewise, the SU identifier developed in our previous research [37], which used advanced deep learning tools such as RoBERTa and human-in-the-loop methods, achieved an accuracy of 80%. Thus, the user base analysis studied in this study does not account for all the substance users.

Second, we recognize that our study's focus on English-language posts may have limited the generalizability of our findings. By excluding non–English-speaking populations, we may have overlooked diverse racial groups and specific age groups in SU discourse. The focus on English-language content, combined with the lack of geocoding analysis, likely overrepresents English-speaking regions, particularly the United States, while underrepresenting global SU patterns. In addition, the user base identified in the study does not investigate the frequency of posts. Analyzing retweeted posts or frequent users could reveal deeper insights that may help public health policy makers develop more targeted and effective strategies.

Third, for the demographic identification, we relied on various machine learning models, such as m3inference and EthicolrM. Although we validated the tools with our ground data, the bias in these models still exists. For age and gender, we only achieve 80% validation accuracy using the m3inference model, which perhaps is due to the specific training dataset that did not fully capture the diversity of Twitter users. For race, our Ethicolr-based pipeline classified only on average of 65% (4.3 million/6.6 million) of users across study years, with unclassified users potentially skewing results if racial groups differed in their likelihood of providing identifiable metadata. This limitation is compounded by the model's training on US census data, which may not generalize to global or non-Anglicized naming conventions, and our reliance on only English-language posts. Thus, we acknowledge that these tools may have introduced biases in the extraction of age, gender, and race. This could have potentially affected the representativeness and accuracy of our findings.

Fourth, we acknowledge that the observed demographic trends (eg, male vs female participation) may be confounded by the inherent demographic distribution of Twitter users. Normalizing these trends by Twitter user base proportions for each demographic could provide a more accurate representation; however, such data are not publicly available, limiting our ability to perform this analysis.

Fifth, our analysis is limited to a single platform, Twitter, which might not fully represent the broader spectrum of SU discourse across other social media platforms such as Facebook, Instagram, TikTok, and Reddit.

Sixth, we acknowledge limitations regarding comparative analyses with survey data. While our findings show meaningful alignments with reports such as NSDUH and NCDAS, important methodological differences must be considered: our real-time social media data capture immediate discourse rather than the annualized behaviors reported in surveys; clinical surveys use validated screening tools such as Alcohol Use Disorders Identification Test, whereas our classifier detects broader public discourse, including news and advocacy content; and NSDUH's nationally representative sampling contrasts with Twitter's self-selected user base. These factors suggest that our temporal trends should be interpreted as complementary to, rather than confirmatory of, survey findings.

Finally, we acknowledge the limitation of the studied themes. While we referenced key COVID-19 factors derived from our primary study [37], the trends could have been influenced by other societal factors such as political tensions. Furthermore, the keywords used in identifying themes may have been too narrow, potentially leading to an overrepresentation of certain themes in our results.

Future Work

This study focused on analyzing SU differences from the perspectives of age, gender, and race. To enhance understanding, future work could incorporate geolocation data to analyze trends and patterns, enabling exploration of region-specific influencing factors. This would enable the development of targeted intervention strategies to prevent SU based on geographic location. Furthermore, extracting additional information, such as socioeconomic, mental, and physical health status, could significantly enhance the use of social media as a prominent platform for studying public health–related issues. In addition, analyzing user-based personality traits could provide valuable insights for the public health sector, allowing for the identification of specific characteristics that can inform prevention strategies, even in the absence of demographic information.

To address the limitations identified in this study, future research could also expand the analysis to include multiple languages, leveraging multilingual NLP models to capture a more comprehensive understanding of SU discourse across diverse linguistic and cultural contexts. Developing and using more robust, inclusive, and transparent demographic inference models trained on diverse datasets would further enhance the representativeness of findings. Future studies could also explore normalizing demographic trends by the underlying user base proportions of social media platforms, if such data become available. This would provide a more accurate representation

XSL•FO
RenderX

of demographic participation and strengthen the generalizability of findings. In addition, expanding the scope to include other social media platforms (eg, Facebook, Reddit, and Instagram) and offline data sources (eg, surveys and interviews) would provide a more holistic view of SU discourse during public health crises. Collaborations with researchers fluent in non-English languages, as well as social scientists and ethicists, could help refine these tools and methodologies to better account for intersectional identities, cultural contexts, and global perspectives.

Conclusions

Social media platforms, combined with advanced NLP technologies, offer a valuable alternative research space for uncovering insightful trends and patterns in SU discourse. This study has successfully demonstrated the potential of leveraging Twitter's data to analyze SU trends during the COVID-19 pandemic, aligning our findings with notable survey-based reports, such as NCDAS and Monitoring the Future. Our results highlight significant demographic shifts, such as the increased engagement of teenagers and male users in substance-related discussions, as well as substance-specific patterns, including the rise in alcohol discourse and the gender disparities in prescription medication discussions.

These insights offer actionable strategies for public health stakeholders, enabling targeted interventions for groups considered to be high risk and substance-specific harm reduction. By leveraging social media as a real-time surveillance tool, stakeholders can monitor trends, disseminate prevention messages, and engage populations considered to be at risk without relying on traditional surveying methods. This study underscores the potential of social media data to inform public health strategies, particularly during global crises, and emphasizes the need for future research to include multiple platforms and languages to enable more inclusive and impactful interventions.

Abstract

Background: By increasing exposure to drug-related advertisements, the illicit digital drug trade promotes drug normalization and eases access to substances, increasing the likelihood of initiation. Social media platforms play an increasingly important role in facilitating the online substance trade by leveraging encrypted communications and user-friendly interfaces to advertise a large variety of readily available substances. Despite its growing importance, there is a paucity of research conducted in Thailand that aims to determine the types of substances, marketing strategies, and public health risks linked to drugs advertised on social media.

Objective: This study aimed to inductively explore the content of tweets on the social media platform X (formerly known as Twitter) advertising drugs in the Thai language.

Methods: Tweets advertising psychoactive substances in the Thai language were collected manually between April and July 2024. A qualitative content analysis was performed on the collected tweets. Tweets were coded based on 5 themes: types of substances advertised, marketing strategies, delivery methods, number of substances per tweet, and location references. The intercoder reliability for each theme was assessed using Krippendorff α, achieving substantial agreement across most codes.

Results: A total of 3832 tweets advertising drugs were collected and analyzed. Most tweets (2424/3832, 63.26%) mentioned 5 or more substances, with depressants such as opioids (2807/3832, 73.25%), antihistamines (2394/3832, 62.47%), and benzodiazepines (2009/3832, 52.42%) being the most frequently advertised. Common marketing techniques included direct contact information (2848/3832, 74.32%) and fast delivery (1216/3832, 31.73%). Delivery methods primarily involved courier services but generally offered multiple options. Tweets that mentioned at least 1 sex-performance enhancer were frequently (422/543, 77.7%) advertised in combination with benzodiazepine.

Conclusions: The results of this study suggest the presence of a large number of substances advertised for sale on the X platform in the Thai language. This digital form of drug trading is facilitated by possible direct messaging and the large number of courier services existing in Thailand. Our findings call for the development of real-time monitoring systems that harness drug-related data from social media to inform public health practitioners about emerging substances and trends and address the challenges posed by the digital drug trade.

Introduction

Background

The rapid and constant development of digital technologies has gradually facilitated the transactions of illicit substances, from the first transaction in 1972 between university students using their institutions' Arpanet accounts (email predecessor) [1] to current social media–based purchases. In the early 2000s, Clearnet or Surface websites sold semi-illicit substances, such as pharmaceutical drugs without a prescription and novel substances listed as "plant food," "research chemicals," or "spice" and advertised as "not for human consumption" [2-4]. A decade later, in the early 2010s, most of the online drug distribution transitioned to darknet markets, also called "cryptomarkets." Cryptomarkets are online marketplaces located within the "Darknet" that rely on advanced encryption techniques and cryptocurrencies (eg, Bitcoin and Monero) to provide anonymity to merchants and buyers [5].

More recently, results from several international studies suggest that psychoactive substances are now increasingly advertised on the "clearnet" (ie, the portion of the internet that can be accessed through classic web browsers). Since the end of the 2010s, messaging services offering advanced encryption and real-time group messaging [6-10], as well as social media applications allowing interactions and user-generated content sharing, have started taking an important role in digital drug trading [11-15]. It is important to note that in the Thai context, social media platforms tend to be used as advertising platforms. Substances are advertised using images and specific keywords that can be searched or directly seen in the user's feed, while "messaging services" (eg, Line) are ultimately used as communication means, allowing encrypted direct messaging between the seller and potential buyer [16]. More precisely, drug dealers have started using Discord servers [13] or messaging services such as Signal and WhatsApp to directly reach out to their customers or repetitively advertise their products on popular social media platforms, such as X (formerly known as Twitter), Telegram, TikTok, and Instagram [16-21]. The ease of access to online markets combined with a friendly user interface and integrated anonymity tools has transformed "classical" drug buying experiences by limiting the chance of arrest, reducing violence, and offering convenient options for drug purchase [22,23].

In addition, the illicit distribution of drugs through online media has rapidly expanded during the COVID-19 pandemic. The pandemic has accelerated the development and use of e-commerce and delivery or courier systems (eg, Grab, Lineman, etc), offering new alleys for drug distribution. The combination of quarantine and increased accessibility of drugs online has led numerous drug users to purchase their drug of choice through the internet. Results from the Global Drug Survey indicate that the percentage of respondents who have used any online platforms to purchase drugs went from 4.7% in 2014 to 15% in 2020 [24]. Meanwhile, the number of online pharmacies and websites advertising pharmaceutical products has also grown rapidly in the past decade, increasing the likelihood of potential misuse of pharmaceutical products with psychoactive effects [25]. Overall, online media facilitates the distribution of a wider variety of drugs by making them readily available and easier to access by having the products come to the buyer rather than the user going to the dealer [7].

Although the number of studies investigating the digital drug trade has drastically grown in recent years, these studies were generally conducted in Western settings, while a limited number of such studies focused on Asian countries. For example, in Thailand, only 2 studies have investigated the illicit distribution of drugs through online media. Thaikla et al [26] collected Facebook posts related to kratom and cannabis in the Thai language from 2015 to 2016. Their results suggested that most Facebook users had a positive attitude toward both cannabis and kratom, that they were advertised online, and that posts did not contain warnings concerning potential negative health effects linked to cannabis or kratom [26]. Pinyopornpanish et al [27] studied the availability of sedatives and analgesics on websites and Facebook. Their results indicate that these drugs were advertised on a large number of Thai websites and 14 Facebook pages. None of these pages or websites contained information about potential harms linked to sedative or analgesic use, and several advertised these substances as potential "date-rape drugs" [28]. These 2 investigations were pioneers in Thailand and provided early snapshots of how online distribution has penetrated Thai social media. However, these 2 studies did not aim to characterize the type and volume of substances advertised on Thai social media. These studies have not been followed by more extensive research aiming to deepen and broaden our understanding of this phenomenon.

This Study

Despite the growing volume of psychoactive substances advertised and purchased online, there is a dearth of research on the types and characteristics of substances available online in Thailand, as well as the semantic content of such advertisements. This study aimed to provide initial insights into the content of tweets illicitly advertising psychoactive substances on X in the Thai language. X is frequently used for substance use surveillance as it contains unedited casual disclosures of "day-to-day" drug encounters as well as illegal or deviant behaviors [17,29-37]. Moreover, X users are mostly young and young adults (Insider Intelligence [38]), which constitute the main age groups consuming psychoactive substances in Thailand [39]. Indeed, X has grown in popularity in recent years, with over 14.7 million active users in early 2024, representing 20.4% of the Thai population [40].

Methods

Data Collection

Tweets illicitly advertising psychoactive substances on X in the Thai language were collected from April 1, 2024, to July 31, 2024. As collecting data from X for free is now limited to a maximum of 1500 tweets per month, and that X robot [41] explicitly forbids the use of any automated "bot" to collect most data from its website, a research assistant was tasked to manually collect tweets based on Thai drug-related keywords weekly. These keywords were selected based on a snowballing technique consisting of 3 steps: first, several tweets were queried based

XSL•FO
RenderX

on a few initial drug-related Thai search terms (eg, [HiCool], "" [green-yellow], "" [Xanax], "" [sell drugs], and "" [Promethazine] [42,43]); second, keywords and hashtags used to describe substances in the collected tweets advertising drugs were identified, and; third, accuracy of new potential keywords was checked by a Thai native speaker (NM) and added to the list of search terms if deemed accurate. This process was repeated until no new drug-related keywords were identified. A total of 88 keywords were identified through this process (Multimedia Appendix 1). This inductive process does not allow for the list of psychoactive substances used as keywords to be exhaustive, but it does allow for the search terms to be contextualized; therefore, they are more likely to be accurate in the X environment. Moreover, manual search does not allow for filtering of tweets according to language; therefore, the list of search terms aimed not to include terms in English to avoid noise.

Tweets were collected based on several inclusion and exclusion criteria. Inclusion criteria were as follows: tweets that (1) were publicly available, (2) contained mention of at least 1 psychoactive substance illicitly advertised, and (3) clearly indicated an intention to sell a product (eg, mention of gram per Thai Bhat, delivery methods, or sale-related terms) were collected. Tweets advertising solely cannabis were excluded from this study as both the medical and recreational use of cannabis were legal in Thailand at the time of data collection [44-46]. In addition, tweets describing user experiences, prevention messages, or news media articles were also excluded.

The research assistant connected to X weekly to retrieve tweets of interest based on the aforementioned inclusion and exclusion criteria, manually copying the text and date and time of each identified tweet in a single CSV file. Duplicated tweets were discarded based on the date and time and text of collected tweets at the end of the data collection period. Tweets advertising solely e-cigarettes (or tobacco cigarettes) were also removed from this analysis due to their large number requiring a separate study dedicated to the topic. It is also important to note that the manual data collection was not limited to tweets posted during the data collection period but also contains tweets before May 2024.

Data Analysis

Texts manually extracted from collected tweets were then analyzed using a qualitative content analysis approach. This type of analysis is conducted in three overlapping stages: (1) development of a coding scheme by a team of coders, who have read and reread an initial sample of tweets; (2) consistent application of codes to the entire body of the tweets, ensuring that meanings are not lost; and (3) an interpretation and analysis phase that aims to establish a pattern for the whole by relating the codes to one another [47]. The "coding scheme" was developed by coding a subset of 500 random tweets from the total dataset of 3832 collected tweets. This subset was used to explore meanings, discuss discrepancies, and develop and refine the coding rules. The inductive approach in qualitative coding, which is also referred to as "open coding" [48], moves from the specific to the general (bottom-up approach) and allows examination of phenomena within their own context rather than from a predetermined conceptual basis. Intercoder reliability was tested for each category using Krippendorff α [49]. Krippendorff α of 0.667 to 0.80 indicates moderate agreement, and greater than 0.80 indicates substantial agreement. On the basis of the preliminary discussion among coders, the coding scheme included the codes shown in Textbox 1.

XSL•FO
RenderX

Textbox 1. Coding schemes and codes.

Number of substances advertised

- Collected tweets tend to advertise several substances in the same post. The number of substances was categorized as "1," "2 to 4," and "≥5."

Marketing strategies

- Five selling techniques were detected during the initial discussion among coders.
  - Discount: sellers offered a discount for higher purchase volumes.
  - Credibility: sellers specified that the ordered products will be delivered.
  - Fast delivery: sellers described 1 or several methods for the products to be delivered in a short period.
  - Direct contact: sellers provide their Line ID or telephone number to be directly contacted by potential buyers.
  - Quality: sellers describe their products as high quality, potent, and pure.

Location

- During their initial exploration of 500 random tweets, the coders noticed that some tweet texts contained a mention or specification of a province (eg, Chiang Mai and Nonthaburi) or a town or a location (eg, Pattaya and Sukhumvit Soi 4), most likely to provide information regarding the area or town where the dealer can meet or send the purchased products by courier.

Types of drugs

- The substances advertised in the 500 initial tweets were categorized into 11 classes
  - Amphetamine-type substances: "Yaba" (methamphetamine in a pill form) and "YaIce" (methamphetamine in crystal form)
  - Opioids: both illicit (eg, opium or heroin) or medical (eg, Tramadol or Neocodion)
  - Benzodiazepine: by chemical name (eg, alprazolam and flunitrazepam), brand name (eg, Xanax), and slang terms (eg, zolam)
  - Antihistamine: promethazine and Procodyl
  - Hallucinogens: magic mushrooms and lysergic acid diethylamide
  - Cannabis (in addition to other substances)
  - Sex-performance substances: Viagra, Kamagra, gamma-hydroxybutyrate, and gamma-butyrolactone
  - Cocaine
  - Ketamine
  - Ecstasy or 3-methoxy-4,5-methylenedioxyamphetamine
  - Others

Methods of delivery

- Three main types of delivery methods were found in the initial tweets
  - Courier: sellers indicate that the purchased products can be delivered at the doorstep of the buyer using a courier service, such as Lineman or Grab
  - Postal: seller would post the substances bought using one of the tracking postal services available in Thailand (ie, Kerry Express or Express Mail Service)
  - Face-to-face: the seller proposed to meet the buyer if located in the same vicinity
- Because a large part of the initial 500 tweets offered the 3 aforementioned options cumulatively, a "multiple" code was created to complete this theme.

Ethical Considerations

The Mahidol University Social Sciences Institutional Review Board approved the research (2024/032.2202).

Results

Data Collection

Over the 4 months of the data collection period, 3832 unique tweets were collected. These 3832 tweets were divided among 3 Thai native coders for content analysis.

XSL•FO
RenderX

Intercoder Reliability Results

The results of the intercoder reliability assessment are displayed in Table 1.

To the exception of the marketing strategy "quality" code and to a lesser extent "antihistamine" type of substance, the 3 coders achieved a Krippendorff α score greater than 0.8 across all other codes, indicating substantial agreements.

Table 1. Intercoder reliability assessment results.

Themes	Average pairwise agreement (%)	Krippendorff α
Number of drugs advertised	90	0.84
Location	96	0.83
Marketing strategies		
Discount	97.1	0.89
Credibility	95	0.82
Fast delivery	97.1	0.89
Direct contact	97.8	0.95
Quality	93.4	0.65
Delivery method	97.2	0.93
Types of substances		
Amphetamine-type substances	98.3	0.88
Opioid	94.2	0.87
Benzodiazepine	94.1	0.87
Antihistamine	89.2	0.74
Hallucinogens	99.9	0.88
Cannabis	98.4	0.80
Sex-performance substances	97.3	0.81
Cocaine	99.8	0.88
Ketamine	99.4	0.80
MDMA[a]-type substance	99.3	0.94

[a]MDMA: 3-methoxy-4,5-methylenedioxyamphetamine.

Qualitative Content Analysis Results

Multimedia Appendix 2 displays the overall results of the qualitative content analysis based on the codes and themes that emerged during initial exploration.

Most collected tweets (2424/3832, 63.3%) advertised 5 or more substances (Table 2). This can denote that either online sellers are generally advertising a wide range of substances or that they intentionally added drug-related hashtags or keywords to increase the range of X users that will be exposed to their advertisements. Specific locations or provinces were advertised in slightly more than a third (1322/3832, 34.5%) of collected tweets. This percentage can be explained by the different methods of delivery used by X sellers (described subsequently).

Most marketing strategies were found in less than half of the collected tweets, with the exception of "direct contact." In total, 74.32% (2848/3832) of the collected tweets contained a Line ID or a telephone number to enable direct messaging or communication between potential buyers and sellers.

Nearly half (1895/3832, 49.45%) of collected tweets did not specify any delivery method. Most of the tweets (1596/3832, 41.57%) that contained a delivery method offered several options for purchased products to be delivered. If only 1 method was proposed, "postal" and "face-to-face" were the least common, with 0.84% (32/3832) and 1.33% (51/3832) of collected tweets, respectively.

XSL•FO

[a]MDMA: 3-methoxy-4,5-methylenedioxyamphetamine.

[b]Not applicable.

Concerning the types of substance advertised, depressant-type drugs, opioids (2807/3832, 73.25%), antihistamines (2394/3832, 62.47%), and benzodiazepines (2009/3832, 52.42%) were the 3 most frequently advertised substances. Stimulant-type drugs were less frequently advertised with amphetamine- and MDMA (3-methoxy-4,5-methylenedioxyamphetamine)-type substances present in 19.72% (756/3832) and 13.39% (513/3832) of collected tweets, respectively. Ketamine and sex-performance substances were advertised in 14.24% (546/3832) and 14.17% (543/3832) of collected tweets, respectively. Cannabis products (in addition to other substances) were advertised in 11.12% (426/3832) of tweets. Rarely advertised substances were cocaine (59/3832, 1.54%) and hallucinogens (44/3832, 1.15%). Notably, (heroin) was mentioned in only 4.59% (129/2807) of tweets that advertised opioids (opium, synthetic heroin, and fentanyl were not mentioned), indicating that most of the advertised opioid substances were diverted medications.

Most Common Substances Advertised in Combination

The most common classes of substances advertised in combinations with each other were determined (Table 2). Cocaine and hallucinogens were removed from this calculation due to their infrequent mention in collected tweets.

Depressant substances (ie, opioids, benzodiazepines, and antihistamines) were frequently advertised in combination. Cannabis was also frequently advertised with these substances. Stimulant-type substances (ie, amphetamine- and MDMA-type substances) were frequently advertised together as well as with opioids and ketamine. Sex-performance enhancers were frequently found in combination with depressant substances, especially benzodiazepines: 77.7% (422/543) of advertisements that contained at least a mention of a sex-performance enhancer also contained at least 1 mention of a benzodiazepine).

Discussion

Principal Findings

This exploratory study aimed to provide initial insights regarding the content of tweets illegally advertising psychoactive substances in the Thai language. The results of the qualitative content analysis suggest that a large variety of drugs are available online and that most of the substances illegally advertised on X are from the depressant class of drugs. Sellers also engage in different marketing techniques to draw the attention of potential buyers and facilitate purchases through private communication and various delivery methods. Our results indicate that most of the collected tweets illegally advertising psychoactive substances cover multiple drugs at once, with a large proportion marketing 5 or more substances. To the best of our knowledge, this is one of the first qualitative content analyses of tweets that illegally advertise drugs online and, more specifically, in the Thai context.

As mentioned previously, most of these tweets were from the depressant class of drugs that were frequently advertised together. The polyuse of depressant-type substances, especially in cases where opioids are involved, could have severe harmful consequences. Although benzodiazepines are generally combined with opioids to enhance their effects [50,51], their combination has been linked to acute respiratory depression [52] and could potentially cause unintentional overdose deaths [53]. Similar to benzodiazepines, antihistamine medications, originally used to treat allergies, can exacerbate opioid induced

XSL•FO
RenderX

sedation [54], potentially heightening chances of overdose [55]. It is important to note that an antihistamine mixed with opioids and a soft drink, a cocktail named "YaPro" in Thailand, is prevalent among young Thai users and has been linked to transitioning to heroin among young Thai males [42]. In addition, antihistamines advertised online could be counterfeit, potentially leading to additional adverse consequences. At least 2 illegal laboratories producing counterfeit antihistamines were raided in Thailand a few months before this manuscript was written [56,57]. The recreational misuse of medications is not a new phenomenon in Thailand. Chittrakarn and Assanangkornchai [58] investigated the misuse of therapeutic drugs, indicating the important role played by online shops in facilitating the purchase of such substances. However, the impact of social media, and more specifically, how social media use influences the online purchase of drugs, remains unknown in Thailand. This calls for additional research on the topic, whose results can help develop education and prevention messages limiting the potential harmful consequences linked to depressant polyuse.

Although depressant-type drugs were more frequently advertised compared to stimulant-type drugs, methamphetamine (in both pill and crystal forms) remains the most commonly used illicit substance in Thailand [59]. This can be at least partially explained by the fact that this study only collected tweets from X. Future research should collect data from several social media and messaging apps to establish if specific substances are more or less prevalent and can be sourced more or less easily on specific platforms. It also calls for understanding to what extent Thai people source methamphetamine through an online or offline mode.

Another important finding from this research is that sex-performance enhancer–type drugs were frequently found to be advertised in combination with depressants, especially substances from the benzodiazepine class. Benzodiazepines can be misused to induce sedation and lethargy in a person without their knowledge. Flunitrazepam or Rohypnol, called the "Blue Tongue" drug in Thailand, has been detected from 2022 to 2023 [60,61] and has been linked with several hospitalizations. There is a paucity of research in Thailand on the prevalence of benzodiazepine use in the general population, and among the youth in particular, as well as the number of emergency visits linked to the unintentional consumption of benzodiazepines.

While it is known that social media drug dealing is "between cryptomarkets and street-based drug markets" [62], involving online advertisements finalized by a physical encounter "face-to-face" (if not combined with other modes of delivery, such as "courier" and "postal") was one of the least frequent mode of delivery proposed in collected tweets that contain mentions of any delivery method. This could be explained by the ubiquitous presence of courier-based services in Thailand (eg, Grab and Lineman) and by the ease of using such services. In contrast with Western settings, this specificity warrants further investigations to assess the volume of courier-based drug delivery through a consumer-based survey. In addition, advertisements collected during this study tend to encompass several marketing techniques, such as bulk orders, discounting, or "credit score." These strategies, frequently used in e-commerce, suggest the existence of competition in the Thai illicit digital drug market as well as the presence of scammers. Understanding the perceived benefits and negative experiences encountered by Thai people who order drugs online would help identify potential risks and related harms inherent to illicit digital drug purchases. This information can then be used to design evidence-based prevention and harm minimization messages that can be disseminated on social media of interest.

Furthermore, sellers appear to frequently provide a telephone number or a messaging app ID (eg, Line direct messaging app) to facilitate communication with potential buyers, which echoes findings from research conducted in other countries [62]. It needs to be specified that Line app messaging is fully encrypted, guaranteeing that communication between sellers and buyers remains anonymous and Line application programming interface does not offer the option of crawling user-generated content. Digital ethnography studies could investigate Line groups dedicated to drug use in the Thai language to gain additional information regarding the digital drug trade in Thailand.

Overall, monitoring online advertisements of drugs sold illicitly can provide early insights on both existing and emerging trends as well as novel substances available on the Thai drug market. Additional efforts should be dedicated to creating and deploying a monitoring system able to collect and analyze not only drug-related advertisements in a timely manner, but also user-generated content linked to substance use in order to better inform practitioners as well as the general population. In its 2023 report, the International Narcotic Control Board recommended addressing the illicit digital drug trade by combining law enforcement actions and public health harm reduction and prevention campaigns to raise awareness and educate the general population [63]. In the same report, the International Narcotic Control Board also proposed that governments work in partnership with tech companies to detect and timely remove illegal content, such as drug advertisements. In Thailand, efforts have mostly focused on arresting online dealers; for example, the Thai Royal Police cooperated with postal delivery agencies, such as the Thailand Post and Kerry Express, to arrest several dealers [64]. However, a recent report from the Thai International Technology Transfer Center underscored that drugs were still advertised on social media (primarily X and Facebook), targeting young adults through 24-hour delivery, cash-on-delivery, and promotional assurances [65]. Dealer arrests or website and market closures tend to redirect the digital drug trade to other vendors or new websites [66]. The results from the Thailand International Technology Transfer Center investigation and from this study suggest that the illicit digital drug trade remains persistent in Thailand. Concerning harm minimization and prevention efforts, Thai nongovernmental organizations (especially the O-Zone Foundation or the Thai Drug Users' Network) have successfully reduced harms linked to injection drug use; however, to the best of our knowledge, there is no online service dedicated to inform and educate social media users about the potential threats involved in online drug purchasing. Such an online information platform could help reduce the burden linked to the illicit digital drug trade.

XSL•FO
RenderX

Despite the difficulties inherent in collecting data from social media for free, future similar studies should aim to obtain a larger dataset based on additional keywords and for an extended period. Future research could use the keyword snowballing method used in this study and combine slang terms with official drug-related terms in order to maximize the number of relevant context-based keywords for data queries. In addition, images from posts illicitly advertising substances could be collected and analyzed to further enhance the findings (eg, collect brand names, verify the type of substance advertised, etc). The question about how social media use (eg, time spent online and platforms used) affects this form of purchase should also be addressed by conducting an online survey among people who buy drugs online. Finally, future national household surveys should incorporate questions that pertain to online drug buying activities to gain insights regarding the prevalence of illicit online drug purchases in Thailand.

Limitations

This study is not without limitations. Most of them are inherent in the field of social media data analysis. First, data collection was not exhaustive. As of July 11, 2023, X has decided to revert the access of “academic” accounts to “free” accounts, which limited the number of tweets that can be collected from 10 million to 1500 per month. This reversal prevents the ability to automatically collect a large volume of tweets through their application programming interface for free; hence, our data collection might not have captured the totality of tweets advertising illicit drugs. While the manual collection used for this exploratory study yields enough data, it is a tedious and inefficient method that can only produce (from our understanding) partial results. Second, data collection was limited to tweets written in the Thai language, which does not guarantee that all collected tweets were posted from within the Kingdom of Thailand. Third, there is no certainty that the sellers illegally advertising the substances found in the collected tweets were really in possession of these drugs. Some vendors were most likely scammers, impacting the final results of this exploratory study.

Conclusions

In conclusion, our analysis demonstrates that a wide variety of substances, particularly depressant-type drugs, are frequently advertised on the Thai X platform. Dealers also appear to leverage courier services and anonymity tools inherent to social media apps to facilitate drug distribution. Importantly, a large number of collected tweets advertised several substances in combination, heightening the risks of health-related harms linked to (intentional or unintentional) polysubstance use. This exploratory study provides preliminary data on understanding the scope of the digital drug trade in Thailand. The results of this study also call for the urgent development of real-time monitoring systems harnessing drug-related data from social media. Such a system can better inform public health practitioners about emerging substances and trends and ultimately help address the challenges posed by the digital drug trade in Thailand.

Acknowledgments

This study was supported by the Center for Addiction Studies (grant 66-00111-0026 to the principal investigator, FRL). The funding source had no further role in the study design; the collection, analysis, and interpretation of the data; the writing of the report; or the decision to submit the paper for publication.

Abstract

Background: There has been a recent proliferation of anti-LGBTQ+ (lesbian, gay, bisexual, transgender, queer/questioning) legislation being proposed in the United States, including more than 500 bills across 42 states in 2024. Many of the studies examining the impact of anti-LGBTQ+ legislation have focused specifically on the association with mental health outcomes.

Objective: The objective of this study was to use social media data to more broadly explore health-related concerns of anti-LGBTQ+ legislation among sexual minority men in the United States.

Methods: We leveraged a dataset containing 70 million tweets that were posted by 23,276 users in the United States who self-reported on Twitter that they are sexual minority men. First, we searched these tweets for keywords related to LGBTQ+ legislation. Next, we developed a codebook for identifying those that expressed health-related concerns of anti-LGBTQ+ legislation. Then, we developed a coding scheme to categorize these concerns into one or more themes by using an inductive approach. Finally, we automatically identified the users' geographic location and age for subgroup analyses.

Results: Among 8486 keyword-matched tweets, 493 (5.8%) tweets expressed health-related concerns due to anti-LGBTQ+ legislation and were posted by 288 sexual minority men in the United States: 112 (38.9%) who posted about *health care*, 84 (29.2%) about *safety*, 64 (22.2%) about *mental health*, 62 (21.5%) about *general harm*, 49 (17%) about *human rights*, and 40 (13.9%) about *support*. *Health care* was the top concern overall and across the United States and age groups. In contrast, the higher prevalence of *mental health* was driven by the larger number of users in the South, as it was less of a concern in other regions. Similarly, *mental health* was less of a concern among older age groups. *Safety* was as much of a concern as *mental health* overall and across the United States and most age groups.

Conclusions: Our findings may inform a broader range of health interventions and approaches for targeting them at specific populations of sexual minority men. By demonstrating that these concerns are expressed on social media, our findings can be leveraged by advocacy groups to amplify voices and rally public support for countering anti-LGBTQ+ bills.

Introduction

There has been a recent proliferation in anti-LGBTQ+ (lesbian, gay, bisexual, transgender, queer/questioning) legislation being proposed in the United States, including more than 500 bills across 42 states in 2024 [1]. Many bills target youth, including 78 bills that would age-restrict gender-affirming health care and 209 that would restrict schools. For example, Florida's Parental Rights in Education Act (HB 1557), commonly referred to by critics as the "Don't Say Gay" law, was passed in 2022 and has prompted other states to introduce similar legislation that prohibits public schools from instruction on sexual orientation or gender identity and from withholding confidential disclosures from students' parents. Many of the studies examining the impact of anti-LGBTQ+ legislation have focused on mental health [2-5]. Other studies that have taken more exploratory approaches using thematic analysis have been limited to a specific age group (85.8% aged ≤21 years) [6] or geographic location (one state) [7]. Although social media has been used to explore the impact of equitable LGBTQ+ legislation [8], it has not been used to study anti-LGBTQ+ legislation. The objective of this study was to use social media data for a thematic analysis that more broadly explores health-related concerns of anti-LGBTQ+ legislation among sexual minority men, including by geographic location and age.

Methods

Ethical Considerations

The institutional review boards of the University of Pennsylvania (828972) and Cedars-Sinai Medical Center (STUDY00002429) deemed this study exempt. The data used in this study were publicly available at the time of collection and were collected and analyzed in accordance with the Twitter terms of service. We have slightly paraphrased the sample tweets to deidentify the users.

Study Population and Data Collection

We leveraged a dataset from our prior work containing 70 million tweets that were posted by 23,276 users in the United States who self-reported on Twitter that they are sexual minority men [9]. We searched these tweets for *parental rights in education* or *don't say gay*, including in hashtags, or keywords related to both legislation (*legislation*, *bill*, *bills*, *law*, *laws*, *policy*, *policies*, *ban*, *bans*, *banning*, *proposal*, *proposals*) and LGBTQ+ (*lgbt*, *lgbtq*, *gay*, *bisexual*, *trans*, *transgender*, *queer*, *sex*, *gender*, *saygay*). Our query returned 8486 tweets, excluding retweets, posted by 2857 users between September 2009 and September 2022.

Thematic Analysis

We used 200 of the 8486 tweets—1 random tweet per user—to develop a codebook for identifying those that expressed health-related concerns of anti-LGBTQ+ legislation (Multimedia Appendix 1). We adopted the World Health Organization's (WHO's) broad definition of *health* as "a state of complete physical, mental and social well-being" [10]. We included nonpersonal experiences but excluded references to federal, international, or equitable legislation. To assess interannotator agreement, 2 authors (AZK and KS) coded an additional 200 tweets. After resolving disagreements, one of the authors (KS) labeled the remaining 8086 tweets.

We used 50 tweets to develop a coding scheme for categorizing the health-related concerns into one or more themes. In contrast to a *deductive* (theory-driven) approach, we used an *inductive* (data-driven) approach to thematic analysis and focused more on themes that captured explicit, rather than latent, patterns of meaning [11]. To assess interannotator agreement, 2 authors (AZK and KS) coded an additional 50 tweets. After resolving disagreements, one author (KS) coded the remaining tweets. For subgroup analysis, we used automated tools to identify the users' geographic location based on the metadata of their tweets and user profiles (Carmen) [12] and age based on explicit self-reports in their tweets (ReportAGE) [13].

Results

Among 8486 keyword-matched tweets, we determined that 614 (7.2%) tweets, posted by 339 users, expressed health-related concerns of anti-LGBTQ+ legislation. Interannotator agreement was 96%, and Cohen κ was 0.80 [14]. Among the 339 users who had been automatically identified [9], we manually validated that 288 (85%) self-reported being sexual minority men (Table 1). Among the 614 tweets, 493 (80.2%) were posted by 288 validated users.

XSL•FO
RenderX

Table 1. Sample tweets posted by a single Twitter user that illustrate true positive (tweet 1) and false positive (tweet 2) self-reports of being a sexual minority man and true positive (tweet 3) and false positive (tweet 4) self-reports of age. The timestamps indicate that this user was aged 51 years at the time of expressing a health-related concern of anti-LGBTQ+ (lesbian, gay, bisexual, transgender, queer/questioning) legislation (tweet 5).

	Tweet	Timestamp
1	As a gay man coming of age in the 80s, I often think about what the world would be like if society had focused on HIV as much it has on COVID. These vaccines are miraculous.	January 15, 2021
2	Coming out as a pro athlete, especially in the NFL, is not easy. I thank Carl Nassib for his courage to be his authentic self as a gay man, and I look forward to him signing with a new team.	March 16, 2022
3	I turned 50 today. Turning 50 during a pandemic isn't exactly what I had planned, but life happens. My friends shipped me a birthday cake, which I'll eat as we celebrate on Zoom.	May 11, 2020
4	Passing Prop E is probably the worst political failure I have seen in my 23 years of living in San Francisco. It will reduce funding for affordable housing/transit and push out start-ups/nonprofits.	March 4, 2020
5	Alabama's anti-trans law forces students to use birth-assigned-gender restrooms & requires teachers to out students to their parents, putting their safety at risk. It's hard to overstate how harmful this law is. It will cause the death of trans kids.	May 8, 2022

Among the 493 tweets, we coded 202 (41%) as *health care*, 106 (21.5%) as *general harm*, 99 (20.1%) as *safety*, 77 (15.6%) as *mental health*, 51 (10.3%) as *human rights*, and 43 (8.7%) as *support* (Table 2). Strict interannotator agreement—that is, for all themes per tweet—was 76%, and Cohen κ was 0.70. The two authors agreed on at least one common theme for 94% of the tweets. Among the 288 users, 73 (25.3%) posted multiple tweets; so, users who posted less frequently may be underrepresented. Counting each theme once per user, 112 (38.9%) posted about *health care*, 84 (29.2%) about *safety*, 64 (22.2%) about *mental health*, 62 (21.5%) about *general harm*, 49 (17%) about *human rights*, and 40 (13.9%) about *support* (Table 2).

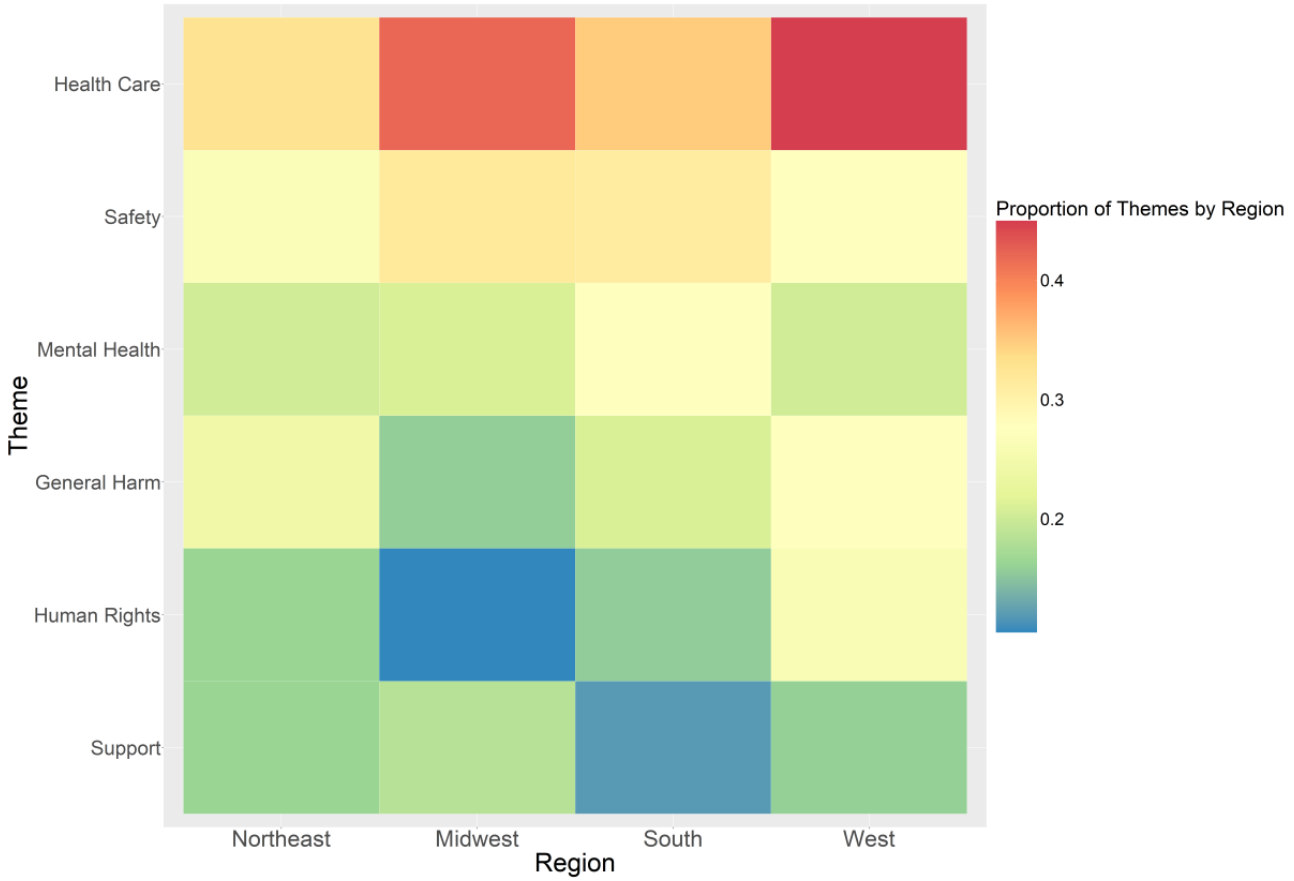

Table 2. Definitions, examples, and numbers of tweet-level and user-level themes of health-related concerns of anti-LGBTQ+ (lesbian, gay, bisexual, transgender, queer/questioning) legislation expressed on Twitter by sexual minority men in the United States.

Theme	Definition	Example tweet	Tweets (n=493), n (%)	Users (n=288), n (%)
Health care	Barriers to health care, such as banning gender-affirming care, allowing providers to refuse care, and denying insurance coverage.	They were forced to move after Arkansas banned gender-affirming care for trans minors. The law would have prevented their sons from taking testosterone.	202 (41)	112 (38.9)
Safety	Threats to safety, such as violence, harassment, hate crimes, and unsafe school and home environments.	Alabama's anti-trans law forces students to use birth-assigned-gender restrooms and requires teachers to out students to their parents, putting their safety at risk. It's hard to overstate how harmful this law is. It will cause the death of trans kids.	99 (20.1)	84 (29.2)
Mental health	Negative impacts on mental health, such as depression, anxiety, stress, and suicide.	@[username] received approximately 4000 crisis contacts from transgender and nonbinary youth in Texas alone in 2021. Many directly stated that they feel stressed and are considering suicide as a result of anti-trans laws, including sports bans, being debated in the state.	77 (15.6)	64 (22.2)
Human rights	Violations of human rights, such as unconstitutionality, discrimination, and oppression.	Our leaders in Florida are taking our rights away one by one, day by day. The don't say gay bill just passed another round of votes, which prohibits the word gay and other lgbt terms in schools, and also requires teachers to out their students.	51 (10.3)	49 (17)
Support	Lack of support, such as removing safe spaces from schools, limiting discussion and resources, feeling isolated, and inhibiting identity disclosure.	According to the Mayo Clinic, kids can identify genders by 18 months and can have a sense of their own gender by 3 years old. Discussing gender and love is not the same as discussing sexual acts. Supporting kids is hindered by these laws.	43 (8.7)	40 (13.9)
General harm	Concerns about harm in general, without specifying another theme.	I knew I was gay at 8 years old. This erasure will be harmful in the long term, guaranteed. #DontSayGay	106 (21.5)	62 (21.5)

Carmen [12] identified the geographic location for 265 (92%) of the 288 users, including 36 states: 49 (18.5%) in the Northeast, 38 (14.3%) in the Midwest, 109 (41.1%) in the South, and 69 (26%) in the West [15]. *Health care* and *safety* remained the top concerns across all regions (Figure 1). In contrast, the higher prevalence of *mental health* was driven by the larger number of users in the South (27.5%), as it was lesser than other concerns in the Northeast (20.4%) and West (20.3%). The relatively low prevalence of *support* was also driven by the larger number of users in the South (11.9%), as it was equivalent to or more than other concerns in the Midwest (18.4%) and Northeast (16.3%).

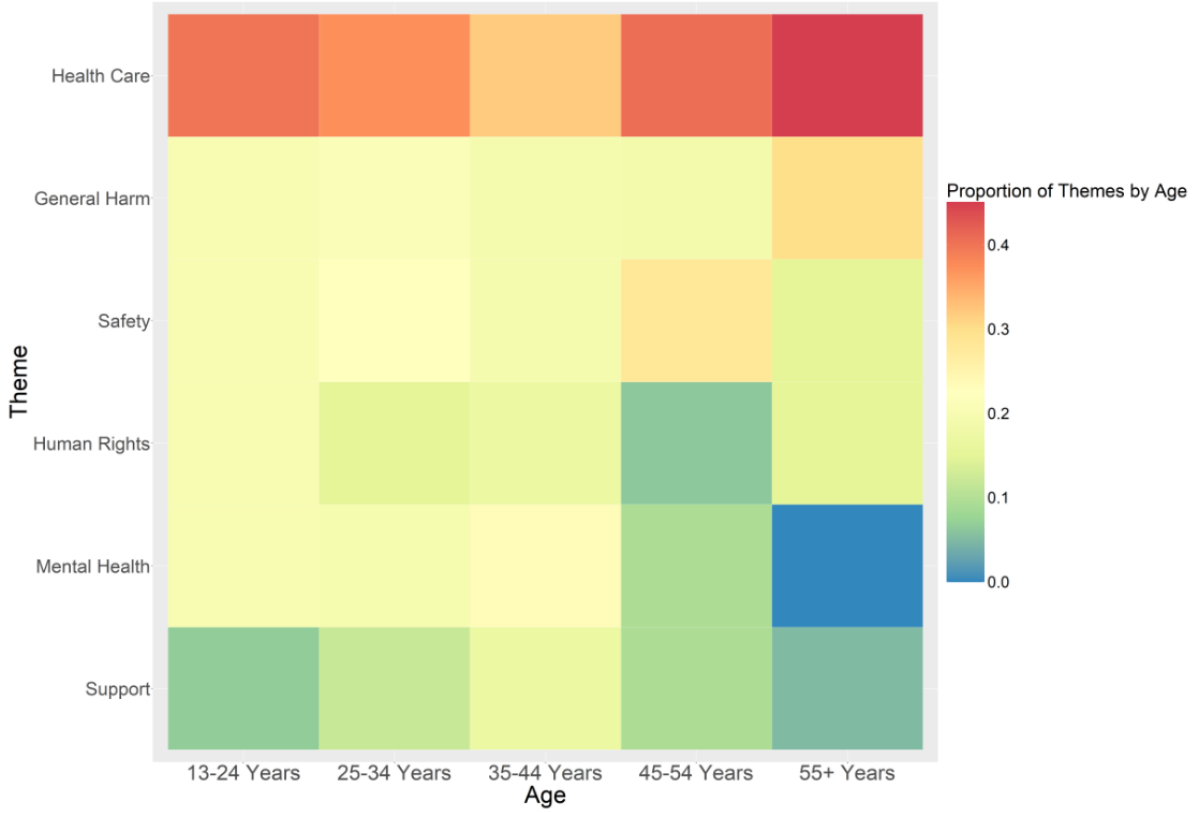

Figure 1. Health-related concerns of anti-LGBTQ+ (lesbian, gay, bisexual, transgender, queer/questioning) legislation expressed by sexual minority men on Twitter, by United States region (n=265).

ReportAGE [13] extracted the age for 188 (65.3%) of the 288 users, with 181 (62.8%) that were manually validated (Table 1). The timestamps that determined the users' age with respect to the tweets in our thematic analysis showed that 15 (8.3%) users were aged 13-24 years, 67 (37%) were aged 25-34 years, 47 (26%) were aged 35-44 years, 32 (17.7%) were aged 45-54 years, and 20 (11%) were aged ≥55 years. *Health care* remained the top concern across all age groups (Figure 2). Although *safety* remained the next highest concern in the age groups of 25-34 years (22.4%) and 45-54 years (28.1%), it was less prevalent in the 35-44 years age group (19.1%) compared to *mental health* (23.4%). *Mental health*, however, was relatively low in the 45-54 years (9.4%) age group and not expressed in the ≥55 years age group (0%). Although *support* remained a relatively low concern across all age groups, it was more prevalent in the 35-44 years age group (17%).

Figure 2. Health-related concerns of anti-LGBTQ+ (lesbian, gay, bisexual, transgender, queer/questioning) legislation expressed on Twitter by sexual minority men in the United States, by age (n=181).

Discussion

Principal Results

In this thematic analysis, *health care* was the top concern overall and across all regions and age groups. Our finding that *safety* was more of a concern in the Midwest and South than in the Northeast and West may reflect that many bills are being proposed in the Midwest and South, including 411 (77.5%) in 2024 [1]. Thus, concerns in the regions that would be more directly impacted by anti-LGBTQ+ legislation have focused more on specific and personal harms such as physical and life-threatening ones. Likewise, *mental health* was more prevalent than *general harm* in the Midwest and South, and *support* was more prevalent than *general harm* and *human rights* in the Midwest. In contrast, *human rights* was more prevalent than *mental health* and *support* in the West.

The variation of *mental health* across age groups may also reflect those who would be more directly impacted by anti-LGBTQ+ legislation—in particular, youth. Our finding that *mental health* was more prevalent among younger age groups supports findings that, among the general population, younger generations are more likely to report mental health concerns [16]. Although it may appear surprising that *support* was more prevalent in most of the older age groups, their tweets reveal many personal accounts reflecting on past experiences that raise concerns about the current generation of youth: “Had a friend text me about ‘Don’t say Gay’ bill and wanted my thoughts on it. Told him my experience as a kid and that I wish I had someone to talk to or resources about how I was feeling.”

Strengths and Limitations

Our findings demonstrate that social media can be used to capture health-related concerns expressed by those who are directly impacted by anti-LGBTQ+ legislation. Based on our exploratory approach using thematic analysis, we found that *safety* was as much of a concern as *mental health* [2-5] overall and across the United States and most age groups. Our sample (n=288) was substantially larger than that in prior thematic analyses [6,7], addressed their limited distribution of age [6] and geographic location [7], and given that over 40% of the users were in the South, captured the voices of individuals who are least likely to discuss their sexual orientation in traditional settings [17]. Despite these strengths, our sample primarily included cisgender men and was collected solely from Twitter, which limits the generalizability of our results to the broader LGBTQ+ community and users of other social media platforms.

Conclusions

We used social media for a thematic analysis of health-related concerns of anti-LGBTQ+ legislation among sexual minority men in the United States. Our findings may inform a broader range of health interventions and approaches for targeting them at specific populations of sexual minority men. By demonstrating that these concerns are expressed on social media, our findings can be leveraged by advocacy groups to amplify voices and rally public support for countering anti-LGBTQ+ bills. Directions for future work include incorporating data from more diverse LGBTQ+ identities and social media platforms.

Abstract

Background: The quality of health information on social media is a major concern, especially during the early stages of public health crises. While the quality of the results of the popular search engines related to particular diseases has been analyzed in the literature, the quality of health-related information on social media, such as X (formerly Twitter), during the early stages of a public health crisis has not been addressed.

Objective: This study aims to evaluate the quality of health-related information on social media during the early stages of a public health crisis.

Methods: A cross-sectional analysis was conducted on health-related tweets in the early stages of the most recent public health crisis (the COVID-19 pandemic). The study analyzed the top 100 websites that were most frequently retweeted in the early stages of the crisis, categorizing them by content type, website affiliation, and exclusivity. Quality and reliability were assessed using the DISCERN and JAMA (Journal of the American Medical Association) benchmarks.

Results: Our analyses showed that 95% (95/100) of the websites met only 2 of the 4 JAMA quality criteria. DISCERN scores revealed that 81% (81/100) of the websites were evaluated as low scores, and only 11% (11/100) of the websites were evaluated as high scores. The analysis revealed significant disparities in the quality and reliability of health information across different website affiliations, content types, and exclusivity.

Conclusions: This study highlights a significant issue with the quality, reliability, and transparency of online health-related information during a public health challenge. The extensive shortcomings observed across frequently shared websites on Twitter highlight the critical need for continuous evaluation and improvement of online health content during the early stages of future health crises. Without consistent oversight and improvement, we risk repeating the same shortcomings in future, potentially more challenging situations.

health information; quality assessment; JAMA benchmarks; DISCERN; infodemic; health crisis; public health; Journal of the American Medical Association

Introduction

Background

As the COVID-19 pandemic unfolded, the world faced unprecedented challenges, prompting urgent and restrictive responses globally. Governments across the globe responded with unprecedented measures, such as closing international borders, lockdowns, and travel restrictions [1,2]. These extensive restrictions disrupted global connectivity and daily routines [3].

Digital channels, including social media, are widely used for communication and community-building in noncrisis times, but their use was scaled and intensified during the COVID-19 pandemic [4], becoming critical for delivering timely updates, guidance, and a sense of connection amid enforced isolation, especially in limited-income and resource countries and remote areas, where they provide immediate access to vital health information and enhance patient autonomy [5,6]. The use of social media resources during the COVID-19 pandemic was driven by multiple concerns, including public interest in understanding the cause, illness, treatment, interventions, and circulating information, including misinformation and disinformation, leading many to seek health care information on social media [7-9]. The shift to digital platforms during the pandemic is double-edged [10]. While they efficiently disseminate critical information, potentially saving lives, they

XSL•FO
RenderX

also open the door to a flood of false information [11]. In such critical times, where false information can spread like wildfire, the need for reliable and high-quality information is not just important—it is a matter of survival.

Recent research indicates that false information—including misinformation and disinformation (categorized by the author's intent) [12-14]—spreads faster than facts on social media platforms, despite their potential for health education [15]. As the health crisis narratives evolve, distinguishing between fact and false information becomes increasingly difficult [10]. This leads to an "infodemic," which describes the overwhelming spread of information, both accurate and misleading, across digital and traditional channels during a disease outbreak [16]. This includes both accurate scientific information and false narratives that spread across a range of traditional and new communication channels, including social media platforms [17].

Recognizing the serious impact of the infodemic, public health organizations, governments, and social media platforms initiated actions to combat misinformation, disinformation, and the infodemic [18]. In addition to enhancing fact-checking services, platform-level interventions, such as algorithmic adjustments, applying labels and warnings to questionable content to direct users to credible sources, and content amplification policies [10,15], different frameworks, such as Germany's Social Listening and Integrated Analysis and Nigeria's Social and Community Listening Systems, were developed, aligning with fact-checking, to monitor and address the COVID-19 infodemic and risk communication, leveraging real-time data and community insights to support effective public health responses. [19-21]

Ensuring access to reliable health information on digital platforms, such as social media microblogging networks, is a critical challenge during public health crises. During the COVID-19 pandemic, these platforms were key sources of health information [22], though health care providers remained the most trusted [23]. Reliable and trustworthy online health information supports informed health decisions and helps maintain public trust in digital health resources [24-26]. While we admit digital health information includes various sources such as search engines, peer communities, artificial intelligence assistants, and health apps, we mainly focus on social media platforms. Within this broader digital ecosystem, social media platforms, such as Twitter (subsequently rebranded X), function as a key amplification channel, facilitating the widespread circulation of health-related links from government, academic, medical, and news websites [27]. Therefore, assessing the quality of online health information is vital to address these challenges for future pandemics, such as COVID-19.

Ongoing research on analyzing the quality of health information on social media is abundant. Researchers have mainly analyzed the quality of retrieved information from popular search engines, such as Google (Google LLC), Yahoo (Yahoo Inc), and Bing (Microsoft Corporation) and concluded that a significant portion of health information retrieved is of poor quality, further emphasizing the need for enhanced quality assurance protocols across digital health platforms [28-30]. For instance, Cuan-Baltazar et al [31] aimed to assess the quality of online COVID-19 information by analyzing the first 110 results from a Google search. The findings indicated that a significant portion of the websites failed to meet basic quality criteria, highlighting the prevalence of poor-quality health information available to the public.

While research has shown that during health crises, public health agencies and government stakeholders across the globe use social media, such as Twitter, to disseminate information regarding situations, risks, and personal protective action inhibiting disease spread [32,33], the quality of health information on Twitter has not been addressed. To fill this gap and given the significance of the early phases of a health crisis, in this research, we aim to investigate the quality of top-circulated information on Twitter during the early stages of a public health crisis.

Our research specifically examines the quality of information on 100 websites that were most frequently retweeted during the early stages of the COVID-19 pandemic, in March 2020, a defining example of a global public health crisis. Such emergency moments are crucial for spreading accurate and timely information as the public looks for guidance and updates on the rapidly changing situation. We focused on key aspects, such as transparency, reliability, and overall quality of the information. To achieve this, we used the JAMA (Journal of the American Medical Association) and DISCERN tools to ensure a robust analysis. This comprehensive assessment covers the most important elements of evaluating online content, with minimum overlapping of these aspects.

By using these tools in our research, we aimed to provide a detailed and comprehensive evaluation of the quality of health information shared on Twitter. Our findings offer valuable insights into the state of health information on social media and highlight areas that need improvement during the early stages of future health crises. Ultimately, this will contribute to better public health communication and help combat false information for future public health emergencies.

Literature Review

The quality of health-related content on social media is a significant concern due to the proliferation of digital platforms, leading to an unprecedented flow of health information accessible to a broad audience. In the health care domain, there are validated tools developed to assess the quality of health information considering aspects such as quality, reliability, transparency, readability, suitability, usability, design, and understandability. Various tools and frameworks, including DISCERN [34] and JAMA Benchmark [35], have been used for evaluations.

Researchers have used these tools to assess the quality of health information related to particular diseases, such as first metatarsophalangeal joint fusion [36], breast cancer [37], treatment of the mouth in systemic sclerosis [38], cervical cancer [29], type 2 diabetes [39], spontaneous coronary artery dissection [30], pancreatic cancer [28], inguinal hernia surgery [40], thyroid cancer [41], and COVID-19 [42].

Many studies have concentrated on evaluating the quality of health information on websites indexed by search engines, such

XSL•FO
RenderX

as Google [43], Yahoo [44], Bing [45], and AOL (America Online) [46]. Most of these studies have generally concluded that the quality of health information related to various diseases retrieved by search engines was poor, lacking in reliability, transparency, and other key quality metrics.

In literature, other than websites, some scholars have focused on platforms that primarily offer video content to disseminate health information. The quality of health content found on these platforms, such as TikTok (ByteDance Ltd [47]), YouTube (Google LLC [48,49]), Bilibili (Bilibili Inc) [50], Douyin (ByteDance Ltd [51]), Weibo (Sina Corporation [52]), Facebook (Meta Platforms, Inc [53]), Instagram (Meta Platforms, Inc [54]), highlighting the attention given to content reliability, has also been evaluated in the literature.

Although the quality of video content found on social networking platforms, such as Facebook and Twitter, has been analyzed [53], to the best of our knowledge, the quality of health information found on these networks has not been studied. The rapid spread of potentially unreliable health information through these platforms presents unique challenges in ensuring the accuracy and reliability of content. This focus overlooks the unique dynamics of social media platforms, namely Twitter, in the early stages of a health crisis, where information dissemination is rapid and user-generated content plays a significant role. Therefore, a gap remains in the literature regarding the evaluation of health information quality specifically on Twitter, highlighting the need for targeted research in this area. Understanding and improving the quality of health information on microblogging networks, such as Twitter, is crucial for effective public health communication and combating false information during public health emergencies.

Methods

Overview

In this research endeavor, we evaluate websites involved in disseminating information related to the most recent public health crisis (COVID-19 pandemic) on the Twitter platform (subsequently rebranded X). Twitter, a leading social media platform, boasts over 450 million active users monthly and records approximately 6000 tweets per second. Unlike platforms that allow extensive posts, Twitter limits messages to 280 characters, promoting concise and precise communication. This characteristic makes Twitter a powerful tool for quickly spreading ideas on various topics, including politics, news, and global events.

Data Collection Process

We selected March 2020 as our study period, coinciding with the World Health Organization's declaration of COVID-19 as a pandemic. Our data source was the "COVID-19 Tweets dataset" [55], which aggregates English tweets related to COVID-19 collected through the Twitter application programming interface. This dataset contains tweet IDs only, in accordance with Twitter's data sharing policies. We therefore developed a Python (Python Software Foundation) script using the Twarc library to retrieve full tweet content, which we subsequently stored in a MongoDB database. Through this rehydration process, we obtained approximately 28.4 million tweets from March 2020.

Website Selection Process

To examine the information sources users encountered on Twitter, we identified tweets containing URLs and analyzed the most frequently shared links during our study period. We ranked websites by retweet frequency, reasoning that the most retweeted URLs represented the primary information sources users accessed while seeking COVID-19 information. Our analysis concentrated on the top 100 websites based on this ranking. Two researchers independently assessed health information quality across selected websites, resolving disagreements through discussion until consensus was reached.

Exclusion Criteria

We applied several exclusion criteria to ensure analytical focus. Websites offering primarily non-English content, statistical dashboards, video materials, or requiring paid access were removed from consideration.

Two independent researchers assessed the quality of health-related information on these websites, and any disagreement was resolved by consensus before the final analysis.

Website Categorizations

We categorized the websites based on their affiliation, content type, and the focus of their topic and content. The websites were classified by their affiliation (commercial, news, university, medical center, nonprofit organization, or government), the type of content they provided (medical facts, clinical trials, human interest stories, and questions and answers), and the focus of their content (whether the site was exclusively dedicated to COVID-19 or if COVID-19 content was only a part of the site).

Evaluation Frameworks

We applied established evaluation frameworks to assess the transparency, quality, and reliability of the health information on these websites. We used the JAMA benchmarks and DISCERN assessment tools to critically evaluate each website's content. The JAMA benchmarks focus on authorship, attribution, disclosure, and currency, while the DISCERN instrument provides comprehensive criteria for assessing the quality of written health information. This dual-assessment approach was crucial for uncovering insights into the credibility and educational value of the health information being disseminated by the selected websites during a critical period of the pandemic. Multimedia Appendix 1 shows all the criteria of the DISCERN and JAMA benchmarks.

JAMA Benchmarks

Transparency involves disclosing details about how information is produced, which can affect informed decision-making. We assessed this using the JAMA benchmarks, which evaluate 4 key quality criteria: authorship, attribution, disclosure, and currency. Each website was scored based on how many of these criteria were met, resulting in a total score of 0-4. (refer to Multimedia Appendix 1)

XSL•FO
RenderX

DISCERN Instrument

The DISCERN tool includes 3 sections: the first two evaluate the reliability and quality of the information provided in text form while the third assesses the overall quality of the publication. Questions are rated on a scale from 1 (clearly no) to 5 (clearly yes), with scores of 2 and 4 allocated for criteria that are met to a partial extent. To calculate the DISCERN scores, a Microsoft Excel sheet was created, dedicating 1 row for each question. Websites were analyzed individually, and scores for each question were manually entered into the respective cells on a scale from 1 to 5. For question 16, the mode function was applied to the responses from questions 1 to 15. The total DISCERN score for a website was determined by summing the scores from rows 1 to 16, represented in the 17th row as the total score. The highest possible total score is 80 and the lowest is 16, with websites being categorized based on their score as high (65 points or above), moderate (between 33 and 64 points), or low (between 16 and 32 points) in quality (refer to Multimedia Appendix 1)

Piloting the Study

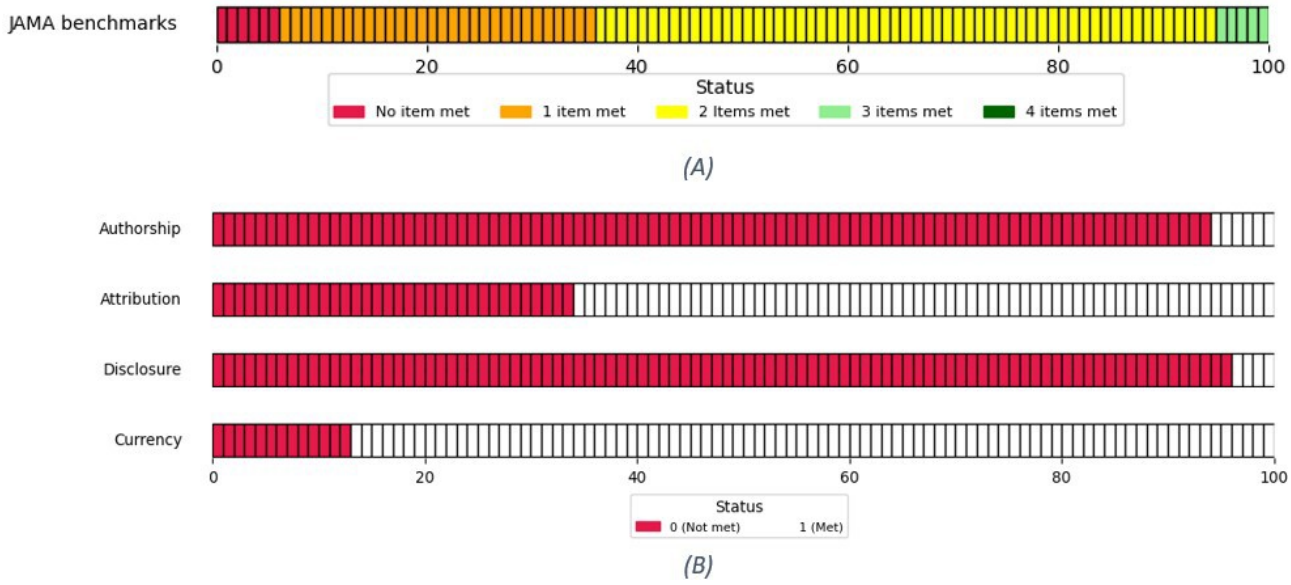
Before evaluating the websites, the study tools were explained to the 2 investigators, and they were taught how to use and score them. They identified and addressed any difficulties and disagreements. Then, they independently assessed 10 websites on different topics and resolved any disagreements.

Analyses

Besides analyzing JAMA and DISCERN scores for each website, we compared them across various categories. Since the data were not normally distributed, we used the Kruskal-Wallis test for the analysis. Post hoc comparisons for the Kruskal-Wallis test were performed using the Dunn test with Bonferroni correction. All statistical analyses were conducted using Python, with significance set at $P<.05$.

Results

Descriptive Statistics



The categorization of 100 websites based on their content's exclusivity, affiliation, and type reveals varied distributions. A significant majority, 89% (89/100) of the sites, are partly exclusive to COVID-19-related content, while 11% (11/100) of the sites are completely dedicated to it. In terms of affiliation, the majority, 69% (69/100) of the sites, are aligned with news organizations, followed by 11% (11/100) of the sites that are commercially affiliated, 8% (8/100) of the sites with government bodies, 6% (6/100) of the sites with medical centers, 4% (4/100) of the sites with nonprofit organizations, and 2% (2/100) of the sites with universities. As for the type of content they provide, 66% (66/100) of the sites predominantly feature human interest stories, 30% (30/100) of the sites focus on providing medical facts, and 4% (4/100) of the sites offer question-and-answer formats.

JAMA Benchmarks

Our JAMA benchmarks analyses showed that none of the websites met all 4 items, 5% (5/100) of the websites met 3 items, 59% (59/100) of the websites met 2 items, 30% (30/100) of the websites met only 1 item, and 6% (6/100) of the websites met no JAMA items. However, the absence of any website that met all 4 benchmarks highlights a significant gap in achieving the highest compliance standard set by JAMA. The distribution of websites based on the number of items met is shown in Figure 1A. On average, all websites achieved a mean JAMA score of 1.63 (SD 0.675). Figure 1B illustrates the percentage of websites meeting each of the 4 JAMA benchmark criteria: authorship, attribution, disclosure, and currency. A vast majority of websites failed to meet the authorship (94/100, 94%) and disclosure (96/100, 96%) criteria, indicating significant gaps in transparency and quality due to the lack of proper authorship and disclosure. These results highlight the overall unsatisfactory and low quality of the information provided by most websites. In addition, a moderate proportion of websites did not meet the attribution criterion (34/100, 34%) and currency criterion (13/100, 13%), underscoring the need for improved adherence to these standards.

XSL•FO
RenderX

Figure 1. Distributions of JAMA benchmarks and 4 criteria. (A) Distribution of JAMA benchmark score (noncumulative). (B) Distribution of each JAMA quality criteria. JAMA: Journal of the American Medical Association.

The JAMA benchmark scores (Table 1) categorize websites based on their exclusivity, content type, and affiliation, displaying the number of criteria met by each group. Notably, no website met all 4 JAMA benchmark criteria, and only 5 websites met 3 items. Surprisingly, no medical center websites met 3 items or more, and no websites with medical facts content met 3 items or more. In addition, only up to 2 items were met.

Table . Distribution of websites meeting JAMA (Journal of the American Medical Association) benchmark criteria by exclusivity, content type, and affiliation.

Categories	No item met	1 item met	2 items met	3 items met	4 items met	Total
Exclusivity						
Exclusive	4	3	4	0	0	11
Partly exclusive	2	27	55	5	0	89
Content type						
Human interest stories	1	19	41	5	0	66
Medical facts	5	10	15	0	0	30
Questions and answers	0	1	3	0	0	4
Affiliation						
Commercial	1	5	5	0	0	11
Government	5	3	0	0	0	8
Medical center	0	2	4	0	0	6
News	0	18	46	5	0	69
Nonprofit organization	0	2	2	0	0	4
University	0	0	2	0	0	2

For example, among the JAMA benchmark results, 5 news-affiliated websites met 3 benchmark items, indicating higher quality, whereas 5 government-affiliated websites met none of the items, reflecting lower quality. These examples are presented in Multimedia Appendix 2.

Table 2 presents the JAMA and DISCERN scores, including mean (SD) and median, across different website types, content types, and affiliations. The statistical analysis using the Dunn Test with Bonferroni correction, with a significance level set at $P<.05$, reveals significant differences in JAMA scores across various categories. Our analysis demonstrates that all websites scored less than or equal to 2 in transparency, with news websites achieving the mean JAMA score of 1.81 (SD 0.55) and government websites achieving the mean JAMA score of 0.38 (SD 0.52). To our surprise, the transparency (JAMA score)

XSL•FO
RenderX

of the analyzed government and medical center–affiliated websites was lower than the news-affiliated websites.

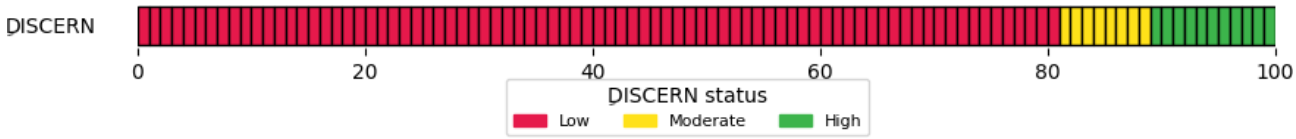


Table . Analysis of JAMA (Journal of the American Medical Association) benchmarks and DISCERN scores.

Categories	JAMA score, mean (SD)	JAMA score, median (IQR)	DISCERN score, mean (SD)	DISCERN score, median (IQR)
Exclusivity				
Exclusive	1.00 (0.89)	1.0 (0.0-2.0)	64.36 (20.55)	73 (56–79)
Partly exclusive	1.71 (0.61)	2.0 (1.0-2.0)	28.84 (10.78)	25 (25–28)
Content type				
Human interest stories	1.76 (0.61)	2.0 (1.0-2.0)	26.32 (6.77)	25 (25–26)
Medical facts	1.33 (0.76)	1.5 (1.0-2.0)	46.57 (22.50)	36 (25–72)
Questions and answers	1.75 (0.50)	2.0 (1.8-2.0)	35.25 (14.75)	32 (24-41)
Affiliation				
Commercial	1.36 (0.67)	1.0 (1.0-2.0)	34.18 (17.84)	25 (25–34)
News	1.81 (0.55)	2.0 (1.0-2.0)	27.20 (6.45)	25 (25–27)
University	2.00 (0.00)	2.0 (2.0-2.0)	50.00 (31.11)	50 (39–61)

DISCERN Instrument

Figure 2 displays the evaluation of 100 websites based on the DISCERN instrument, categorized into 3 levels according to their achieved score: low (16-32 points), moderate (33-64 points), and high quality (65 points or above). The majority of the analyzed websites, 81% (81/100) of the websites, were of low quality according to the DISCERN criteria, 8% (8/100) of the websites were of moderate quality, and only a small portion, 11% (11/100) of the websites, met the high-quality standards. This highlights the urgent need to improve the quality of online health information, as most websites scored low on quality standards. On average, all websites achieved a mean DISCERN score of 32.75 (SD 16.45). In terms of reliability, the mean score is 20.69 (SD 7.05), and for quality of information questions, the mean score is 10.50 (SD 8.79).

Figure 2. Distribution of DISCERN score (noncumulative).

Based on their score, the DISCERN scores in Table 3 categorize websites by their exclusivity, content type, and affiliation into low, moderate, and high quality. Considering the website content type, the ones providing human interest stories (64/100, 64% of our sample) scored low on health quality. Furthermore, it is notable that half of the websites providing medical facts (15/100, 15% of all websites) achieved low quality, despite being expected to be more reliable. No website with questions and answers content type received a high DISCERN score, indicating a need for improvement in information-providing websites. Although the number of university websites is small, it is surprising that 50% (1/2) of university-affiliated websites scored low while universities are expected to meet high academic standards. This assessment underscores a concerning lack of quality and reliability in health information, with a notable trend toward low quality in widely read categories, such as human-interest stories, news, and university-affiliated websites.

XSL•FO
RenderX

Table . Distribution of websites meeting DISCERN scores criteria by exclusivity, content type, and affiliation.

Categories	Low	Moderate	High	Total
Exclusivity				
Exclusive	2	1	8	11
Partly exclusive	79	7	3	89
Content type				
Human interest stories	64	1	1	66
Medical facts	15	5	10	30
Questions and answers	2	2	0	4
Affiliation				
Commercial	8	2	1	11
Government	3	0	5	8
Medical center	1	1	4	6
News	64	5	0	69
Nonprofit organization	4	0	0	4
University	1	0	1	2

The statistical analysis using the Dunn test with Bonferroni correction, set at a significance level of .05, revealed significant differences in DISCERN scores across various categories during the comparisons. As the DISCERN scores' mean (SD) and median are shown in Table 2, our analysis indicates that all affiliations have low to moderate DISCERN scores, which are detailed in Multimedia Appendix 3 (mean, SD, and median of reliability and quality of information by categories). In terms of affiliation, medical centers have the highest DISCERN score (mean 61, SD 19.11), while nonprofit organizations and news have the lowest (mean 24, SD 2 and mean 27.2, SD 6.45, respectively) and tend to be low-qualified in both reliability and quality.

Discussion

Principal Findings

This study assessed the quality of health information of websites that were circulated the most on Twitter during the early stages of a public health challenge, when the increased use of social media and the accompanying anxiety, fear, and human tendency to seek out information drive individuals to social media platforms like Twitter. Using the established tools to evaluate the quality of health information of JAMA benchmarks and DISCERN, the study evaluated the transparency, reliability, and content quality of those websites. The analysis shows a concerning pattern of achieving an overall low DISCERN score (mean DISCERN score of 32.75, SD 16.45), pointing to a widespread issue of poor health information online. Similarly, our examination using the JAMA benchmarks revealed that these sites were generally of poor quality in terms of transparency, as 95% (95/100) of them at most only met 2 out of 4 criteria of JAMA (see Multimedia Appendix 2). These findings emphasize the urgent need for substantial improvements in presenting and verifying online health information, as the overall quality is unsatisfactory and affects its reliability.

Regarding JAMA benchmarks, while the most significant shortcomings were found in disclosure and authorship, our study also uncovered that several websites lacked proper currency and attribution. These elements are crucial for maintaining the relevance and credibility of health-related information. Promoting transparency, establishing credibility, ensuring the information is up to date, and allowing for source verification are essential practices that should be standard across all health-related websites according to JAMA benchmarks.

Regarding DISCERN and considering the websites' affiliation, the average DISCERN score of each affiliation was low to moderate. It is worth noting that while in our analyzed websites, we have seen government and medical center websites that achieved high DISCERN scores, the overall performance of these types of websites is also considered moderate. This indicates that only some websites provided information that could be considered somewhat reliable, highlighting that there is significant room for improvement to ensure the health information provided meets both reliability and quality criteria.

The area where medical center websites fall short in the reliability section of DISCERN is related to addressing uncertainty, while government websites fall short in addressing balanced and unbiased information as well as uncertainty. It should be noted that other websites, which represent a significant portion of all, lacked clear aims, failed to achieve those aims, and demonstrated poor relevance, clarity of sources, and currency in terms of reliability. Moreover, these websites struggled with addressing uncertainty and providing balanced and unbiased information, further affecting their overall reliability. Specifically, in the second section of DISCERN, medical center websites underperformed in areas related to treatment and prevention, such as explaining treatment processes, risks and benefits, the consequences of not treating, impact on quality of life, availability of options, and decision-making support. These gaps highlight urgent areas for improvement to enhance patient understanding and

XSL•FO
RenderX

decision-making capabilities. These sites also underperformed in key areas of information quality, such as explaining treatment options, outlining potential outcomes, and supporting decision-making processes.

Our study is not without limitations. This study faces several methodological constraints that should be acknowledged. Our analysis was restricted to English-language tweets from March 2020, which limits our ability to capture information-sharing patterns within non-English-speaking communities and may not reflect evolving communication behaviors throughout the pandemic. The Twitter application programming interface's data-sharing policies and technical restrictions meant we could only rehydrate 28.4 million tweets from the original dataset, with additional constraints from rate limits and the unavailability of tweets that users subsequently deleted or made private. Our methodology of prioritizing the top 100 tweets with URLs, while useful for identifying widely circulated content, may have introduced a bias in that less shared sources, such as government health portals. The exclusion criteria we applied—removing non-English sites, statistical dashboards, video content, and subscription-based sources—though necessary for analytical consistency, further reduced the comprehensiveness of information sources we could examine. Furthermore, we only had 2 university-affiliated websites in our sample. University-affiliated websites showed moderate levels of information quality according to the DISCERN criteria. This makes it challenging to draw comprehensive conclusions about their overall performance. In addition, we acknowledge that the JAMA and DISCERN instruments evaluate only the quality of website content and do not capture user interaction dynamics, such as tweet framing, images, or retweet patterns. Our focus was therefore limited to assessing the source quality of linked health information, rather than the behavioral influence of how this information was shared on Twitter.

These findings highlight the urgent need to continuously assess and improve online health information. Ensuring that health websites meet high standards of transparency, reliability, and quality is crucial, especially during public health emergencies. This emphasizes the importance of addressing these issues through targeted recommendations to enhance the credibility and reliability of online health information during a public health crisis. Without consistent oversight and improvement, we risk repeating the same shortcomings in future, potentially more challenging situations. Implementing targeted enhancements in editorial standards, transparency practices, and the presentation of health information, along with public education, is crucial to ensure that reliable and credible content is available, especially during public health emergencies. Continuous evaluations are essential to prepare for future crises, where the quality of information will play a key role in shaping public health responses and maintaining public trust.

Implications

The implications of our research for enhancing the overall quality and reliability of the health information provided during the early stages of a health crisis are as follows.

Considering DISCERN, websites affiliated with medical centers, government agencies, and universities generally have higher scores for quality and reliability but still fall into the moderate range. Enhancing quality and reliability involves ensuring detailed and clear information, such as comprehensive descriptions of how each treatment works, the benefits and risks, the consequences of not using treatments, the impact on quality of life, the availability of multiple treatment options, and support for shared decision-making. In addition, implementing regular content updates to ensure information remains current is essential, with dedicated teams assigned to review and update content periodically.

News and commercial websites, although very popular, often provide lower-quality and less reliable information. To improve their DISCERN scores, these websites should implement rigorous editorial standards and quality control measures to ensure accurate, reliable, and unbiased health information. Employing fact-checkers and medical experts to review and verify health content before publication is crucial. Training content creators on best practices for creating high-quality health information, including proper citation of sources and avoidance of sensationalism, will further enhance the quality.

Considering JAMA, websites need to address all criteria, including currency, authorship, attribution, and disclosure, to improve their overall scores. This involves ensuring that health information is up-to-date, clearly authored by qualified experts, properly attributed to credible sources, and transparently disclosed regarding any potential conflicts of interest.

To ensure high-quality health information on platforms like Twitter during a public health emergency, it is crucial to educate the public on identifying credible sources through community programs in schools and workplaces. Social media should enforce strict controls, include health expert reviews, and promote verified content. Clear authorship and easy source access are necessary. Collaborations with health organizations will ensure the dissemination of reliable information, enhancing informed decision-making and public trust. These improvements will boost the overall quality and reliability of health information.

Beyond specific technical and editorial improvements, our study addresses broader and persistent challenges in the health information shared on social media platforms. Rather than offering a retrospective critique of a past crisis, the research highlights systemic issues in online health communication that extend far beyond the COVID-19 context. By applying established quality assessment tools, such as DISCERN and JAMA, we uncovered widespread structural deficiencies—such as the lack of authorship transparency, source attribution, and evidence-based reliability—in widely circulated content on social media. These shortcomings are not crisis-specific. They reveal fundamental vulnerabilities in how health information is produced and disseminated across social platforms. The early pandemic period served as a natural experiment that exposed these weaknesses, underscoring the need for proactive preparedness in future public health emergencies. The principles of transparency, accuracy, and proper attribution must be upheld consistently, regardless of the type of crisis or the platform involved. Moreover, the insights drawn from this study hold enduring relevance, as improving the quality of health

XSL•FO
RenderX

information is an ongoing priority that directly influences public trust, informed decision-making, and effective crisis response.

Building on these broader insights, our findings underscore the importance of actionable intelligence for stakeholders. Public health organizations can implement these insights by developing and disseminating preapproved messaging templates to facilitate rapid and effective crisis communication and by establishing real-time monitoring systems to detect and counter false information trends. Social media platforms are encouraged to adjust their algorithms to prioritize verified health content and to promote centralized, in-platform health information hubs that offer timely and reliable updates developed in partnership with public health experts. Policymakers can support these efforts by enacting regulations that mandate transparency, authorship disclosure, and attribution in digital health content, while also introducing quality certification frameworks that help users recognize trusted sources. They should further consider measures to ensure algorithmic accountability, particularly when it comes to the amplification of misleading health information. Meanwhile, health communicators must integrate structured quality evaluation tools, such as those based on the JAMA and DISCERN frameworks, into their content development workflows. Providing training in health literacy, ethical communication, and false information detection to communication teams will ensure that messages remain trustworthy and effective across diverse audiences. By adopting these cross-sector strategies, stakeholders can collaboratively strengthen the digital health information environment and enhance preparedness for future public health emergencies.

In summary, this study not only reveals critical shortcomings in the quality of health information shared on social media during a public health crisis but also offers a practical roadmap for improving future communication strategies. By addressing both systemic and actionable gaps, our findings contribute to a more resilient digital health ecosystem—one that supports public trust, informed choices, and effective crisis response.

Conclusion

This study reveals a significant issue with the quality, reliability, and transparency of online health-related information, particularly evident during the early stages of a health emergency when social media becomes a primary platform for the dissemination of information. The importance of such evaluations becomes even more pronounced during crises like the COVID-19 pandemic, where access to reliable and high-quality information can significantly impact public health outcomes. The websites analyzed exhibited low quality, with an average DISCERN score of 32.75 (SD 16.45), highlighting widespread deficiencies in health information. Similarly, our analysis using JAMA benchmarks demonstrated generally low transparency, with 95% (95/100) of websites achieving at most 2 JAMA criteria, emphasizing the need for drastic improvements. The extensive shortcomings observed across frequently shared websites on Twitter underscore the critical need for continuous evaluation and improvement of online health content.

Abstract

Background: The COVID-19 pandemic was accompanied by a barrage of false, misleading, and manipulated information that inhibited effective pandemic response and led to thousands of preventable deaths. Recognition of the urgent public health threat posed by this infodemic led to the development of numerous infodemic management interventions by a wide range of actors. The need to respond rapidly and with limited information sometimes came at the expense of strategy and conceptual rigor. Given limited funding for public health communication and growing politicization of countermisinformation efforts, responses to future infodemics should be informed by a systematic and conceptually grounded evaluation of the successes and shortcomings of existing interventions to ensure credibility of the field and evidence-based action.

Objectives: This study sought to identify gaps and opportunities in existing infodemic management interventions and to assess the use of public health frameworks to structure responses to infodemics.

Methods: We expanded a previously developed dataset of infodemic management interventions, spanning guidelines, policies, and tools from governments, academic institutions, nonprofits, media companies, and other organizations, with 379 interventions included in total. We applied framework analysis to describe and interpret patterns within these interventions through their alignment with codes derived from 3 frameworks selected for their prominence in public health and infodemic-related scholarly discourse: the epidemiological model, the socioecological model, and the environmental health framework.

Results: The epidemiological model revealed the need for rigorous, transparent risk assessments to triage misinformation. The socioecological model demonstrated an opportunity for greater coordination across levels of influence, with only 11% of interventions receiving multiple socioecological codes, and more robust partnerships with existing organizations. The environmental health framework showed that sustained approaches that comprehensively address all influences on the information environment are needed, representing only 19% of the dataset.

Conclusions: Responses to future infodemics would benefit from cross-sector coordination, adoption of measurable and meaningful goals, and alignment with public health frameworks, which provide critical conceptual grounding for infodemic response approaches and ensure comprehensiveness of approach. Beyond individual interventions, a funded coordination mechanism can provide overarching strategic direction and promote collaboration.

KEYWORDS

infodemics; misinformation; disinformation; Covid-19; infodemic management; health communication; pandemic preparedness

Introduction

Background

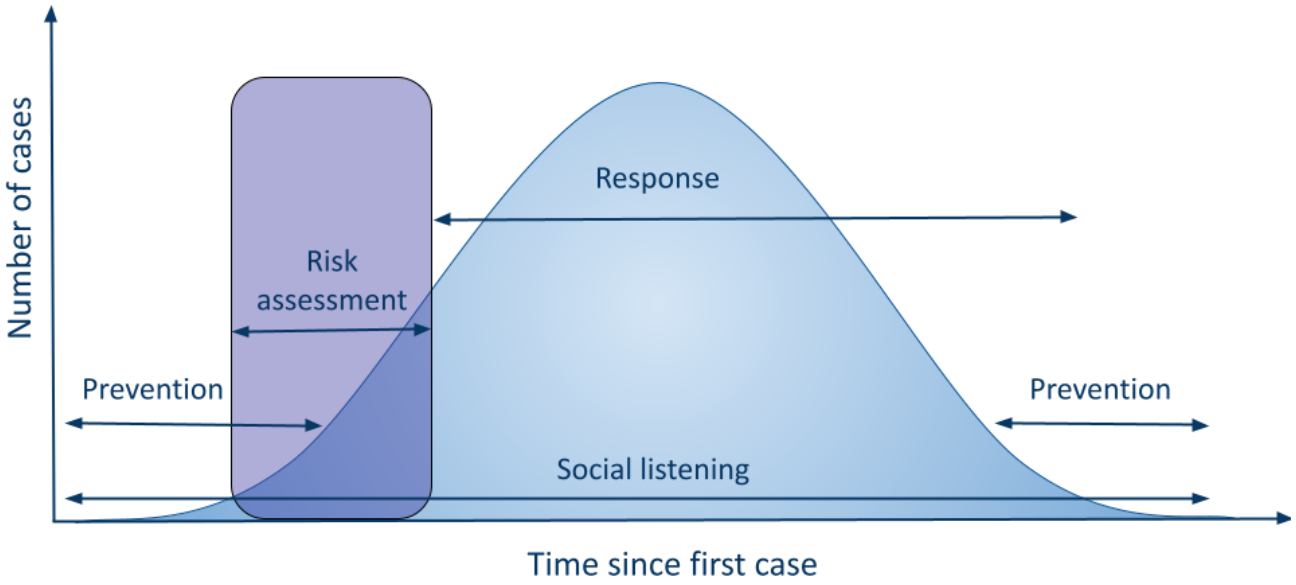
The COVID-19 pandemic entailed an outbreak not only of viral illness but also of viral rumors. This so-called infodemic, defined by the World Health Organization as an overabundance of accurate and inaccurate information [1], had tangible public health consequences. As of April 2022, 24% of COVID-19 mortality, or 234,000 deaths, was vaccine-preventable [2], and misinformation and disinformation cost the United States between US $50,000,000 and US $300,000,000 each day during the pandemic in health care spending and economic losses [3].

XSL•FO
RenderX

These impacts demonstrated the necessity of addressing misinformation as part of public health responses [4].

A wide range of stakeholders globally including governments, nongovernmental organizations, academic institutions, professional societies, and technology companies rapidly developed and deployed a large number of interventions to mitigate the perceived harms of the infodemic. These interventions varied substantially in their foci and impacts and addressed both the infodemic itself and the social problems related to the infodemic, such as vaccine hesitancy and institutional distrust. For example, in the New York City Department of Health and Mental Hygiene, the misinformation response unit disseminated culturally specific communication materials in response to emerging web-based COVID-19 rumors through partnerships with community organizations [4]. YouTube and Google also prioritized credible health information sources in search results based on criteria developed by organizations including the World Health Organization, the National Academy of Medicine, and the Council of Medical Specialty Societies [5,6].

Given the inevitability and growing threat of future infodemics, it is critical to learn from the successes and shortcomings of the growing body of infodemic management interventions. Prior studies have evaluated the effectiveness of these interventions, their fundamental characteristics, and the psychological concepts underlying them [7-9]. However, these studies were limited in the scope of interventions examined, only considered 1 framework, or focused on individual-level factors. Little research has explored the areas of emphasis, both intended and unintended, and strategies revealed and gaps left by these interventions in aggregate. Such an analysis is needed to provide funders, government agencies, public health leaders, and other stakeholders that set priorities for infodemic responses with insights to inform proactive, sustainable, and coordinated efforts that effectively use limited resources. Given increasing politicized attacks on public health and misinformation research in recent years, it is particularly important to avoid infodemic management practices that lead to or exacerbate public mistrust. For example, in the United States, Republicans are disproportionately likely to consider the removal of false articles on social media, a key component of Facebook's COVID-19 misinformation policy [10], to be censorship [11].



In public health, conceptual frameworks serve as lenses that systematically illuminate gaps, patterns, and opportunities in programs and policies [12-14]. Frameworks are not exhaustive or mutually exclusive, and multiple frameworks are necessary to comprehensively interrogate complex topics. Applying public health frameworks to infodemic interventions offers an opportunity to explore their theoretical foundations and inform the design of future interventions. Certain public health metaphors, particularly analogies to epidemics of disease, are frequently invoked in and often dominate discussions of misinformation in academia and public media. However, the use of these frameworks and the validity of their underlying assumptions in this setting have yet to be rigorously evaluated [15]. As a result, other promising mechanisms of impact supported by alternative paradigms may be overlooked [15]. In the following sections, we outline the 3 frameworks applied in this study and their applications to infodemics. These frameworks were selected because they are well established in public health or are often referenced, implicitly or explicitly, in infodemic-related discourse. Public health frameworks were prioritized to reflect the growing application of public health perspectives to address misinformation during the pandemic.

Epidemiological Model

Epidemiological models describe the spread of disease over time within a population. The epidemiological model frames misinformation as a contagion (Figure 1) [16]. As the epidemiological model is currently a dominant paradigm in discourse about misinformation [15], it is critical to assess how well suited previously developed interventions are to this model. Areas of engagement in the information ecosystem are drawn analogously from responses based on public health approaches to infectious diseases: social listening, risk assessment, response, and prevention [17]. Risk assessment can take place either as a one-time evaluation or a continuous assessment at various points along the epidemiological curve.

XSL•FO
RenderX

Figure 1. Epidemiological model.

Socioecological Model

The socioecological model illustrates the health impacts of various components of society and the environment (Figure 2) [18]. Given its widespread application in health promotion and public health [19-22], it is important to evaluate its use in health misinformation. Counterinfodemic activities fit within this paradigm as the information environment is an increasingly recognized determinant of health influenced at multiple levels, from clinical interactions to social media regulation [23]. This perspective indicates a need to comprehensively target misinformation throughout the socioecological spectrum [8], reflected in the US Surgeon General's "whole of society" response to misinformation [24,25] and reports from the World Health Organization and other public health experts [26,27].

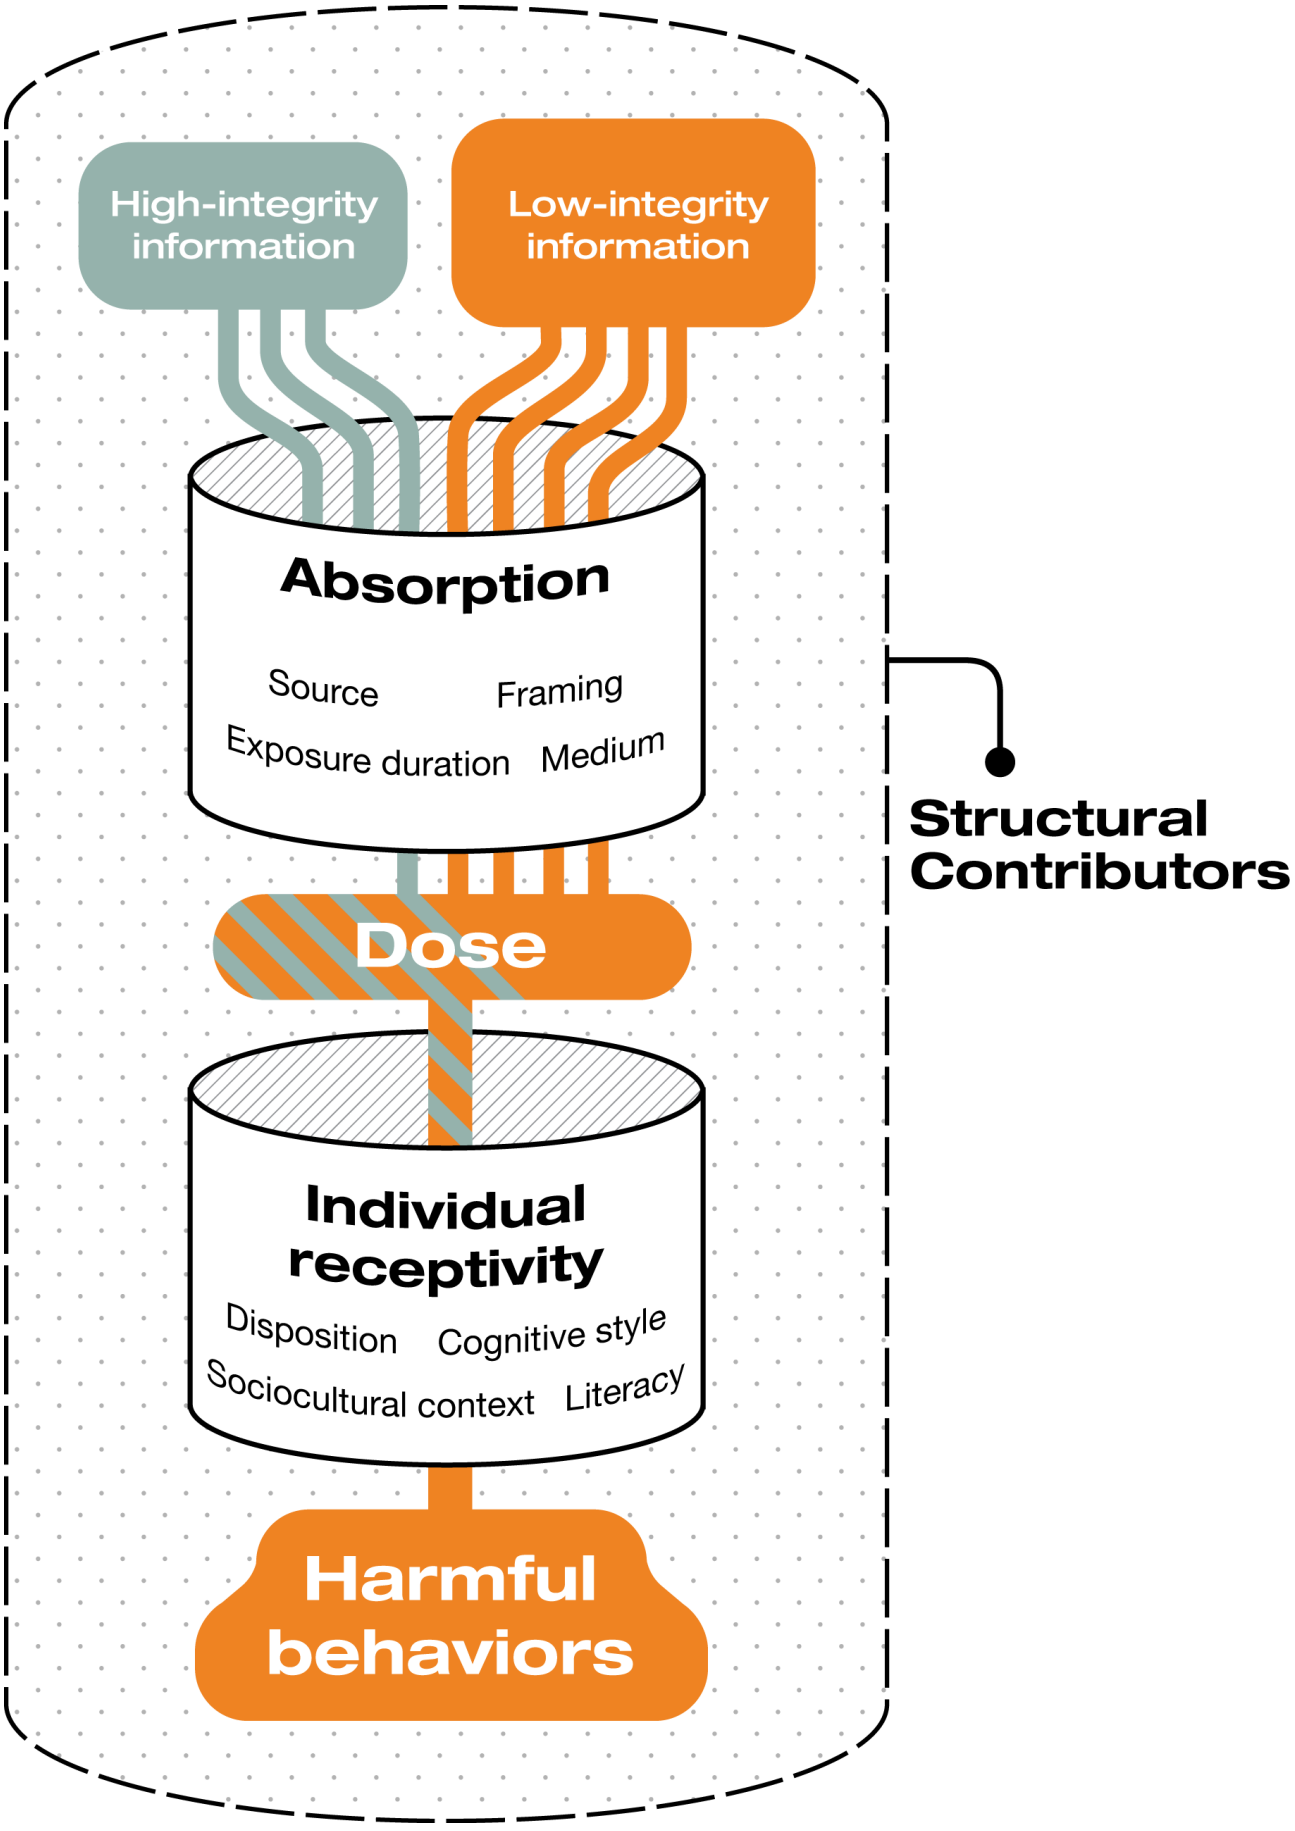
Figure 2. Socioecological model.

Environmental Health Framework

Environmental health is an area of public health focused on the health impacts of the natural and built environment. Despite its decades of use, the term "information environment," previously defined as the space where people receive and process information to make sense of the world [28,29], has only recently been applied to misinformation. In national defense, it was conceptualized to facilitate (often clandestine) information operations [30]. Political science literature has examined to

XSL•FO
RenderX

what extent the information environment is conducive to political knowledge, civil discourse, and other democracy-relevant outcomes [31]. In both instances, the implied orientation of the information environment is toward information producers, rather than information consumers.



Environmental analogies about health-related information challenges have expanded, as scholars have alluded to the toxic effects of a polluted media environment [32,33]. In 2021, the US Surgeon General included the subtitle "Building a Healthy Information Environment" in his special advisory on misinformation [24]. The New York City Commissioner of Public Health, Ashwin Vasan, and the New York City Mayor, Eric Adams, recently urged public health authorities to "treat social media as a toxin, ever present in our daily environments" [34]. Here, the implied orientation is toward information consumers.

Despite the use of environmental metaphors, environmental health frameworks have been underused to understand public health–related information challenges. From a public health perspective, the information environment has been defined as an adaptive space that includes content from traditional and web-based media and in-person sources and technology to access and process this content [35]. This paradigm highlights several mechanisms of misinformation spread and corresponding opportunities for intervention: altering the dose of information of variable integrity to which an individual is exposed, influencing an individual's receptivity to toxic misinformation, assessing the threat posed by a claim or narrative (referred to as hazard identification), and mitigating the harms of information hazards through multipronged approaches (hazard management) (Figure 3). Detailed definitions and examples of each of these intervention types are provided in the "Methods" section.

By applying these 3 models, this study sought to identify gaps and opportunities in an aggregate view of pandemic-related infodemic management interventions and to assess the use of public health frameworks to broadly structure and strategize responses to infodemics.

Methods

Data Collection

This analysis drew on a dataset of infodemic management interventions aiming to address the effects and spread of misinformation that was previously developed as part of a report commissioned by the National Academies of Sciences, Engineering, and Medicine, which ultimately led to a peer-reviewed publication [8,36,37]. These interventions, which were identified between October 2022 and January 2023, include guidelines, policies, and tools from local and federal governments, public health departments, nonprofits, universities, technology and media companies, and other organizations [8]. The original authors identified these interventions through searches of the following sources: academic literature about infodemics and infodemic management; gray literature from organizations including federal agencies, nongovernmental organizations, and technology companies; and websites from state and local health departments [8,36]. Interviews with key informants were used by the original authors to identify additional interventions [36]. We expanded this dataset to include additional interventions lacking from the original dataset, focusing on interventions performed by professional societies that were identified through a similar search strategy, and reviewing the websites and resources of medical and scientific societies. As many societies' interventions were undertaken without either a publication or a description of such interventions on the societies' websites, the goal with this expansion was to be illustrative of these interventions and not exhaustive. The final dataset consisted of 379 interventions and can be made available upon request.

Data Analysis

We used framework analysis, a form of qualitative content analysis useful for applied health policy research [12,13]. Framework analysis provides a comprehensive and systematic approach to describe, interpret, and identify patterns in policies and procedures [12,14]. Codes based on thematic frameworks are applied to cases, allowing data to be compared across and within cases [13]. Through applying frameworks to a given topic, framework analysis can assess the relevance of public health analogies that are frequently applied to health infodemics but have yet to be rigorously defined in this context. Studying multiple frameworks allows for a more comprehensive lens to examine the many dimensions to an issue such as misinformation [13].

Five steps are involved in framework analysis: (1) familiarization, in which the researchers become immersed in the data and reflect on patterns; (2) identifying the thematic framework, based on emerging themes; (3) indexing, or coding components of the data that correspond to themes; (4) charting, which involves rearranging data based on themes; and (5) mapping and interpretation, when themes are analyzed through the charts [12]. We first familiarized ourselves with the data by reviewing the intervention descriptions and websites in the dataset. The thematic frameworks were identified based on prior literature cited in the introduction that provide a range of perspectives to conceptualize misinformation. We developed a coding scheme of deductive codes drawn a priori from the components of the frameworks. This coding scheme accommodated additional inductive codes that emerged through the coding process.

The epidemiological model included the following codes: prevention, social listening, risk assessment, and response. Prevention activities proactively protect populations and information networks from the adverse effects of an infodemic. Social listening activities identify and track harmful (web-based) narratives [38]. Risk assessments determine which narratives require intervention based on factors such as its spread over time, the channels in which it is disseminated, and the communities it affects, with the goal of avoiding expending limited resources on or giving oxygen to low-impact narratives [38]. For example, narratives about vaccines causing infertility that are disseminated widely in the press and on social media during a pandemic would be considered high risk [38]. Finally, rapid responses curtail the spread of harmful information.

The codes derived from the socioecological model included individual, interpersonal, community, organization, and public policy, referring to the societal level at which influence was exerted on the information environment [19]. A public policy intervention was considered to be "a choice made by government to undertake some course of action" involving goals and means of reaching them [39].

The following codes were applied for the environmental health model: dose (which could be further specified as increasing high-integrity information exposure, decreasing low-integrity information exposure, or influencing absorption), receptivity, hazard identification, and hazard management. Drawing from toxicology, "dose" refers to the concentration of low-integrity information compared with high-integrity information, defined as information that is "trustworthy; distinguishes fact from fiction, opinion, and inference; acknowledges uncertainties; and is transparent about its level of vetting," [40] and the degree of absorption of this content [41]. Hazard identification and management are conducted by organizational and governmental entities engaged in infodemic management and information integrity protection. Analogously to toxicology approaches, hazard identification refers to assessing the health effects of an information toxin [42]; hazard management describes multipronged approaches to evaluating and mitigating the threats posed by such a toxin. While structural determinants (eg, health care access or socioeconomic marginalization) influence the information environment, we did not code for this domain in order to focus on the individual components of the information environment that are specific to this model. Examples of each of these codes are given in Table 1.

XSL•FO
RenderX

Table . Example interventions corresponding to each environmental health code.

Code	Examples	Examples
Dose	InVID assists journalists in assessing the reliability of videos on social media, thus facilitating the sharing of high-integrity videos while inhibiting the further spread of low-integrity videos.	[43]
Receptivity	Interland is a game developed by Google that teaches young children to distinguish truths from misinformation on the web.	[44]
Hazard identification	Logically tracks misinformation campaigns to understand threats to national security, corporations, nonprofits, and elections.	[45]
Hazard management	CrossCheck, a program run by First Draft, promotes collaboration and resource sharing for journalists responding to misinformation. The Vaccination Community Navigator Program similarly takes a multipronged approach in educating community health workers to boost vaccine confidence.	[46]

Coding was conducted in an iterative, discursive process. One author (JNJ) coded the entire dataset in batches, documenting evolving code definitions and interpretations of the data, where relevant, multiple codes were applied to the same intervention. After each batch, 2 of the authors met to discuss uncertainties and insights that arose, such as ambiguities in the code definitions and emerging patterns in the data. Coding was conducted iteratively, until thematic saturation was reached [47]. Then, DS independently coded a random sample of approximately 20% of the dataset. Codes were reviewed to ensure alignment and discrepancies were resolved through discussions between both authors.

Results

Overview

Overall, 379 interventions were included in the final analysis, including 14 interventions from professional societies that were identified through the expanded search. The 3 frameworks lended distinct insights into the functions and capacities of the interventions (Table 2). The applications of each of the frameworks are described in detail in the subsequent sections. For further details on the coding results and representative interventions, see Multimedia Appendix 1.

XSL•FO
RenderX

Table . Insights from the 3 frameworks.

Key finding	Framework	Supporting evidence	Infodemic management recommendations
Risk assessments are often value-based or poorly defined.	Epidemiological framework	Vague or absent language about how risk assessments are conducted.	Risk assessments should be rigorous, objective, and transparent about how community values are incorporated into decision-making.
Interventions are skewed toward acting at the individual level and often focus on only 1 level of influence.	Socioecological model	Most interventions were focused on either individuals alone or individual members of organizations, rather than implementing structural change with community, interpersonal, organizational, or policy interventions. Only 11% of interventions received more than 1 socioecological code.	Interventions acting at the interpersonal, community, organizational, and policy levels should be explored, and structural barriers to implementing interventions at these levels should be identified and overcome. Collaborations should involve interventions targeting multiple levels of the socioecological spectrum.
Interventions often lack mechanisms to reach their intended audiences (ie, the Field of Dreams Fallacy) [48].	Socioecological model	Abundance of resources and tools that lacked connections to established workflows and organizations within the socioecological spectrum.	Interventions should be developed in partnerships with the organizations that are intended to use them.
Interventions place a greater emphasis on increasing high-integrity information rather than decreasing low-integrity information.	Environmental health framework	More than 3 times as many interventions address high-integrity as low-integrity content.	Interventions that decrease the spread of low-integrity information should be developed.
Demographic factors are emphasized when addressing receptivity to misinformation, while psychological factors are overlooked.	Environmental health framework	Focus on targeting racial, cultural, or age-related communities.	Interventions should consider approaches to segmenting audiences based on personas and psychobehavioral factors.
Interventions that address receptivity tend to involve a one-time action rather than longitudinal education.	Environmental health framework	Prevalence of self-contained courses, games, handouts, etc, that lack mechanisms to reinforce instruction over time.	Media literacy initiatives should incorporate mechanisms for longitudinal instruction on detecting and responding to misinformation.
Few organizations are equipped to implement hazard management approaches, despite increasing awareness that such approaches are critical.	Environmental health framework	Overrepresentation of tool kits, handbooks, and other resources lacking direct action in the hazard management category.	Media, public health, and government agencies should adopt hazard management approaches.

Epidemiological Framework

By distinguishing between the stages of an infodemic, the epidemiological framework highlighted critical distinctions in the foci of interventions that emerged in response to a specific ongoing or predicted infodemic. This framework was less relevant to interventions that addressed general components of misinformation that were agnostic of a particular crisis, such as tools providing assessments of the credibility of information sources. The framework also did not apply to interventions that lacked a clear audience or mechanism of impact.

In total, 50% (189/379) of interventions were engaged in activities intended to prevent an infodemic itself, in contrast to preventing an individual from falling for misinformation amid an ongoing infodemic. Prevention activities were most prominent when the amount of misinformation was low. Moreover, 19% (73/379) of interventions conducted social listening, monitoring conversations, concerns, claims, and news, online or offline [49]. Social listening tools most often analyzed social media feeds and datasets. The degree of analysis varied widely, from tracking misinformation with artificial intelligence to descriptive statistics on rumor spread. Seven percent (28/379) were risk assessment interventions that assessed the severity or status of an infodemic to inform whether and to what extent a response was needed. These interventions not only provided data that could be relevant to a risk assessment, such as the amount of spread of a rumor, but conducted the risk assessment itself. Most interventions (286/379, 76%) responded to an ongoing infodemic, primarily through fact-checking, debunking, and amplifying reliable information and sources. They also conducted prebunking to address topics for which misinformation is already widespread.

Socioecological Model

The socioecological model allowed for a better understanding of the key groups and audiences that are affected by or are in a position to address misinformation. Applying this framework revealed a skew toward interventions that acted at the individual level, rather than the interpersonal or community levels. While most interventions were directed toward organizations, they required exposure or uptake by individual members, rather than spurring structural change within the organization overall. In addition, interventions often lacked a clearly defined target

XSL•FO
RenderX

group and means of reaching this audience. By revealing these shortcomings, the socioecological model shed light on opportunities to align valuable resources with the groups with the greatest capacity to leverage them.

We identified 150 (40%) interventions that acted at the individual level. These interventions included media literacy and prebunking initiatives, repositories of reliable information, fact-checks and debunks, and tools evaluating the credibility of claims and sources, when these tools were intended for use by the general public. Interventions acting at the interpersonal level, such as an app that provides guidance about discussing vaccines with friends, were the least common, representing only 2% (9/379) of this dataset. Eleven percent (42/379) of interventions were community-level, targeting groups based on educational systems, geographic regions, and racial or ethnic identities, as well as social networks. The interventions often included content or dissemination strategies tailored to a community's needs. The 178 (47%) organization-level interventions primarily provided resources and tools that were intended for members of a profession, such as journalists, researchers, physicians, teachers, librarians, policy makers, or organizational bodies. These resources included infodemic management tool kits, communication materials, social listening platforms, media literacy curricula, reporting guidelines, and social media policies. There were 39 (10%) public policy interventions. Most of these policies were developed by federal governments. Two came from the United States; other regions included Singapore, Australia, the United Kingdom, France, Egypt, Germany, and the European Union.

Environmental Health Framework

The environmental health framework allowed for a more nuanced perspective on the mechanisms through which interventions interacted with the information environment. By outlining a variety of components that contribute to the information environment, this framework underscored the importance of contextualizing misinformation within information networks and audiences.

Most interventions (244/379, 64%) targeted the dose of high- and low-integrity information. More interventions increased the amount of high-integrity information (155/379, 41%) rather than decreasing the volume of low-integrity information (44/379, 12%). We identified 61 (16%) interventions that addressed receptivity to misinformation. Most of these interventions involved media literacy education, including curricula, games, infographics, and web-based courses. Seventeen percent (65/379) of interventions conducted hazard identification by assessing the dose or toxicity of misinformation. These interventions were primarily resources and tools for professionals, particularly infodemic managers, public health communicators, and journalists. The interventions involved content verification, social listening, credibility assessments, and fact-checking. Seventy (19%) hazard management interventions took a comprehensive and higher-level approach to addressing misinformation that went beyond any 1 particular intervention. They often took the form of tool kits, handbooks, field guides, and frameworks intended to inform professional hazard management activities, rather than conducting hazard management themselves.

Crosscutting Insights

We identified several findings that suggest opportunities for future interventions relating to the use of technology, coordination, and sustainability that surfaced from a combination of all 3 frameworks (Table 3). For example, some interventions such as artificial intelligence–powered chatbots suggested an overzealous application of new technologies that lacked grounding in user needs. Perhaps owing to the urgent and unprecedented nature of the COVID-19 pandemic, interventions were often duplicative and short-lived.

Table . Crosscutting insights.

Key finding	Supporting evidence	Infodemic management recommendations
Greater strategic direction to align theories of change with desired impact is needed.	Unclear distinctions between efforts to address acute compared with endemic misinformation as well as efforts engaged in prevention versus response. The intended audiences of interventions also tended to be poorly defined.	Interventions should specify the nature of the infodemics they are intended to address, intentionally select a guiding framework, and address the unmet needs of a specific audience.
Technological tools are often built and used without adequate need finding.	Prominence of tools such as chatbots enabled by technology that do not clearly fill a well-defined need.	The design process for interventions should center around identified needs rather than the tool.
Lack of coordination or pervasive duplication of efforts.	Very few initiatives included cross-sector collaboration; those that did were not sustainably funded to persist beyond the pandemic. A number of initiatives duplicate work and effort (eg, see "tool kits").	Sustainable cross-disciplinary or sector coordination mechanisms may be required to support effective and ethical infodemic management initiatives [50].
Short-term funding opportunities early on in the COVID-19 pandemic were not conducive to long-term sustainability.	Many interventions had concluded or had websites that had not been recently updated.	Sustainability given funding trends should be a key consideration when developing interventions. Funding programs should include support to sustain efforts beyond immediate crises and collect longitudinal data.
The role of incidental information exposure compared with intentional information consumption was rarely accounted for.	Interventions frequently made unsupported assumptions about the degree of agency individuals have in the information they encounter.	Future frameworks should incorporate the distinction between incidental information exposure and intentional consumption.

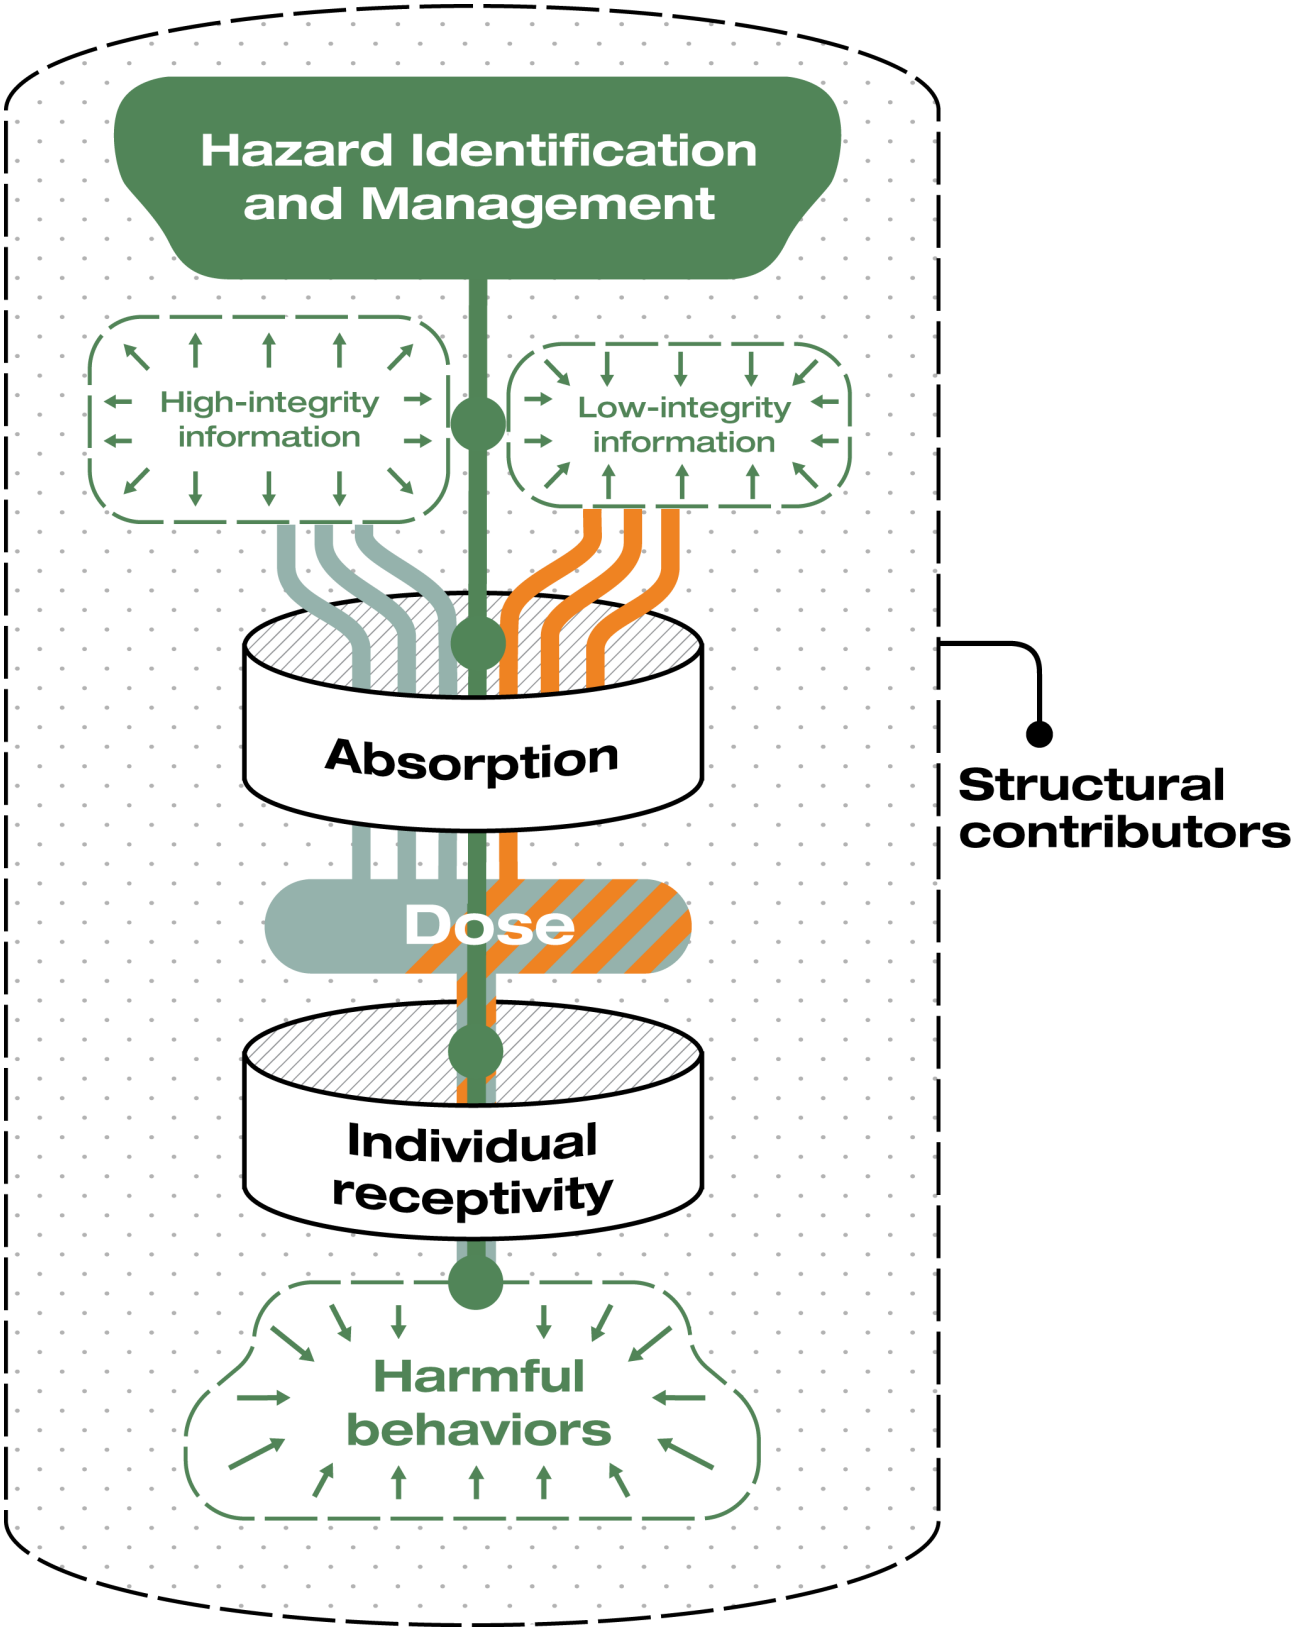
Discussion

In our analysis, the epidemiological, socioecological, and environmental health frameworks shed light on trends, gaps, and opportunities among counterinfodemic interventions. The epidemiological framework revealed an opportunity to implement more robust and transparent risk assessment measures in partnership with communities to triage rumors and allocate resources, particularly as more evidence emerges on the threats posed by various claims and narratives. By relying on value judgments, the risk assessments in the interventions in this dataset risk undermining trust and expending limited resources on low-impact efforts. Instead, the World Health Organization recommends developing risk assessment matrices that synthesize considerations such as the timing of a narrative, its spread on various platforms, and the impacted communities to categorize narratives as high, moderate, or low risk, and positive sentiment [38].



The socioecological framework demonstrated the need to target higher levels of influence through collaborations spanning multiple levels, reinforcing a finding from the original analysis of this dataset [8]. Scholars have recently argued that the outsized attention given to individually framed behavioral interventions "pollutes" the discourse and diverts attention from structural interventions [51,52]. This trend was replicated in our dataset, where structural change through public policy or enduring platform adjustments was rarely the priority. As with other complex public health challenges such as diabetes or drug overdoses, structural-level interventions coordinated with efforts acting at other levels of the socioecological spectrum are likely to be more effective and sustainable than individual-level efforts in the case of infodemic management. Policy efforts to protect children from social media–related harms have garnered significant attention, most notably in the US Surgeon General's recommendation to display warning labels on social media [53]. Despite their limitations, related legislation, such as the Stop Addictive Feeds Exploitation [54], offers potential models for analogous efforts to mitigate the harms of digital infodemicshttps://www.zotero.org/google-docs/?FlRQ40

The socioecological framework additionally revealed the importance of avoiding the Field of Dreams Fallacy [48], as many interventions neglected to specify mechanisms to reach their intended audiences. While the speed of a response is often prioritized in an emergency, the resulting lack of alignment with existing efforts may prove harmful in infodemic management due to the resource and trust barriers to maintaining strong relationships with community partners. Sustaining proactively developed partnerships is needed to increase the uptake and sustainability of infodemic interventions, particularly the tool kits and other resources that were often deployed independently of established partnerships in this dataset.

The environmental health framework provided a structure for systems-level, multipronged approaches that influence the information environment as a whole (Figure 4). A key finding was that reducing exposure to low-integrity information, which digital platforms can implement through content moderation, deplatforming, and algorithmic adjustments, was a notable gap. Amid the growing politicization of content moderation, many social media platforms have recently rolled back these efforts [11,55]. Differing perceptions of trustworthiness and integrity may also reduce the efficacy of content moderation or even lead to further polarization [6,56]. Regulating algorithmic recommendation and amplification may encourage platforms to prioritize high-integrity content while protecting First Amendment rights [57]. While the answer to bad speech was once considered to be "more speech" [58], in the social media era, it is now recognized that freedom of speech does not equate to freedom of reach [59]. Current revenue models incentivize platform architectures and algorithms that promote content that provokes negative emotional reactions, particularly anger [60].

Figure 4. Opportunities for intervention based on the environmental health framework. Points of intervention within this framework are represented by green nodes; for example, interventions can modify individual receptivity to misinformation. The shift in the composition of the information environment toward high-integrity information and subsequent reduction in harmful behaviors as a result of these interventions is indicated with green arrows. Structural contributors influence these dynamics but were not a focus of the present analysis.

While many interventions used demographic characteristics to target the information environments of particular communities, psychobehavioral segmenting may allow for more precise tailoring of messages to individuals uniquely receptive to misinformation (eg, those who engage in absolutist thinking) [61,62]. An information environment perspective additionally suggests that initiatives based on inoculation theory could expand their impact through longitudinal rather than one-time

XSL•FO
RenderX

modes of engagement and by reaching a saturation point that displaces low-integrity information. Hazard management approaches are critical to address an issue as pervasive as an infodemic. Such approaches were uncommon in our dataset, however, likely due to the funding, coordination, and sustainability challenges. Strong governance and financial support are needed to enable key stakeholders, including media, public health, environmental scientists, and government, to create and sustain hazard management approaches, potentially following models such as the Elections Infrastructure Information Sharing and Analysis Center [50].

Several key crosscutting considerations emerged (Table 3). Infodemic management interventions could benefit from greater strategic direction regarding the theories of change applied in various settings. The intended mechanism and audience of an intervention should be informed by a framework that aligns with the relevant type of information distortion. For example, while misinformation is often considered as part of acute infodemics, endemic misinformation unrelated to particular health events may require different theories of change, use of alternate frameworks (eg, socioecologic or environmental), and corresponding interventions. Too often, the development of tools using novel technologies such as generative artificial intelligence centered the technology itself, rather than a need they are intended to address. Need-finding processes must be incorporated into the design of technologically enabled interventions to maximize their potential impact. Design-thinking principles, for example, provide an approach to explore stakeholders' needs and develop tailored solutions [63].

Funders and stakeholders involved in the interventions were often fragmented and uncoordinated, leading to duplication and unstrategic allocation of resources. Well-governed and funded coordination mechanisms, perhaps modeled on Elections Infrastructure Information Sharing and Analysis Center, offer an opportunity to streamline resources while diversifying efforts. Since many efforts to counter the COVID-19 infodemic were not sustained after the immediate threat of the pandemic subsided, funding structures that support longitudinal and crisis-agnostic efforts are needed. Interventions rarely accounted for the distinction between incidental exposure and intentional information consumption. While a consumptive lens suggests that individuals make conscious decisions about the information they encounter, from an exposure-based perspective, individuals are subject to influence by information within their environments. Incorporating this distinction into future frameworks may illuminate new approaches for interventions. Overall, by testing these frameworks in our dataset, we identified their strengths and weaknesses, allowing for iterative adaptation to the infodemic management context.

Our analysis was limited in that not all components of the interventions that we considered, such as reach and distribution, were typically reported. As a result, it was sometimes necessary to make inferences about goals and impacts. Many interventions lacked information about time and scale, which resulted in organizing the data in a way that gave the same prominence to small- and large-scale initiatives. This lack of information biased the data toward smaller-scale initiatives, although large-scale initiatives likely had a broader impact. Many of the codes we applied were subjective, not mutually exclusive, and reliant on interpretation, a limitation that was exacerbated when details of an intervention were not available. For example, for the epidemiological framework, prevention and response entail critically distinct activities, but we were unable to distinguish between these 2 foci when information about the stage of the infodemic at which an intervention was deployed was not provided. There was also at times overlap in the insights derived from each framework; our analysis attempted to focus on the dominant framework that surfaced a given insight. The dataset used in this study is not exhaustive; notably, given the focus on terms such as "infodemic management," a term that emerged during the COVID-19 pandemic, interventions that predate the pandemic may have been underrepresented. Our study was designed to be illustrative, not exhaustive, so it did not use systematic search criteria. This study considered only 3 frameworks, which were chosen based on their prominence in public health and misinformation discourse; future work should consider additional frameworks to illuminate further findings. For example, recent work has adapted a public health prevention framework to infodemic management [64]. Finally, we acknowledge that the feasibility of our recommendations may be limited given resource constraints and an evolving evidence base.

In this study, we used a framework analysis using 3 public health frameworks to illuminate emphases and gaps in interventions to address the COVID-19 infodemic. While many opportunities to expand the reach and impact of interventions were identified, it was also clear that the landscape of infodemic management approaches lacks an overarching strategy and entity responsible for coordinating and evaluating activities. In preparation for future infodemics, emphasis should be placed on multisector collaboration, alignment with measurable and meaningful goals, and top-down approaches to determining and implementing strategies.

Acknowledgments

The authors thank Jack Gorman, Claire Wardle, and Dimitri Prybylski for helpful comments on and discussions about the manuscript. Jenna Sherman, Céline Gounder, and other members of the Reproductive Health Misinformation Working Group contributed to thoughtful discussions of the environmental health framework. The authors also thank Nina Martinez for her graphic design contributions. JNJ conducted the data analysis and composed the manuscript. SG contributed to the development and revision of the manuscript. DS conceptualized, designed, and oversaw the study; contributed to the data analysis; and supported the composition of the manuscript. This work was supported by a grant from the Robert Wood Johnson Foundation (grants 76935 and 78084). An earlier, less rigorous version of this analysis was supported by and published as a report with the American Board

Abstract

Background: The novel coronavirus disease (COVID-19) sparked significant health concerns worldwide, prompting policy makers and health care experts to implement nonpharmaceutical public health interventions, such as stay-at-home orders and mask mandates, to slow the spread of the virus. While these interventions proved essential in controlling transmission, they also caused substantial economic and societal costs and should therefore be used strategically, particularly when disease activity is on the rise. In this context, geosocial media posts (posts with an explicit georeference) have been shown to provide a promising tool for anticipating moments of potential health care crises. However, previous studies on the early warning capabilities of geosocial media data have largely been constrained by coarse spatial resolutions or short temporal scopes, with limited understanding of how local political beliefs may influence these capabilities.

Objective: This study aimed to assess how the epidemiological early warning capabilities of geosocial media posts for COVID-19 vary over time and across US counties with differing political beliefs.

Methods: We classified US counties into 3 political clusters, democrat, republican, and swing counties, based on voting data from the last 6 federal election cycles. In these clusters, we analyzed the early warning capabilities of geosocial media posts across 6 consecutive COVID-19 waves (February 2020-April 2022). We specifically examined the temporal lag between geosocial media signals and surges in COVID-19 cases, measuring both the number of days by which the geosocial media signals preceded the surges in COVID-19 cases (temporal lag) and the correlation between their respective time series.

Results: The early warning capabilities of geosocial media data differed across political clusters and COVID-19 waves. On average, geosocial media posts preceded COVID-19 cases by 21 days in republican counties compared with 14.6 days in democrat counties and 24.2 days in swing counties. In general, geosocial media posts were preceding COVID-19 cases in 5 out of 6 waves across all political clusters. However, we observed a decrease over time in the number of days that posts preceded COVID-19

XSL•FO
RenderX

cases, particularly in democrat and republican counties. Furthermore, a decline in signal strength and the impact of trending topics presented challenges for the reliability of the early warning signals.

Conclusions: This study provides valuable insights into the strengths and limitations of geosocial media data as an epidemiological early warning tool, particularly highlighting how they can change across county-level political clusters. Thus, these findings indicate that future geosocial media based epidemiological early warning systems might benefit from accounting for political beliefs. In addition, the impact of declining geosocial media signal strength over time and the role of trending topics for signal reliability in early warning systems need to be assessed in future research.

KEYWORDS

spatiotemporal epidemiology; geo-social media data; digital disease surveillance; political polarization; epidemiological early warning; digital early warning

Introduction

On March 12, 2020, the World Health Organization (WHO) declared the novel coronavirus disease COVID-19 a pandemic [1]. Its high infectiousness and severity posed a great threat to large populations worldwide, ultimately causing an estimated 15.9 million pandemic-related deaths [2], challenging health care professionals, hospitals, and authorities alike. Thus, decision makers around the world sought to unravel and predict the spreading dynamics of this novel coronavirus. Consequently, researchers explored various ways of adjusting and improving existing epidemiological early warning systems, with complementary internet-based data sources being one such method to better monitor and anticipate how this new disease would affect different geographies around the world [3-5].

Multiple studies have already emphasized the role of geosocial media data in improving early warning of epidemiological phenomena. For instance, geosocial media data were used to improve real-time reporting on diseases like Zika and Ebola [6] or to enhance the prediction of dengue fever [7]. Accordingly, various recent examples further emphasize the ability of geosocial media data for real-time surveillance and early warning in the context of COVID-19 [8,9]. In this regard, Kogan et al [10] observed that in the beginning of the pandemic, increases in geosocial media activity, among other digital data sources, preceded surges in COVID-19 cases by 2 to 3 weeks on state level. Similarly, Zhang et al [11] used geosocial media posts in a linear regression model to predict COVID-19 signals on state-level. Yet, an increasing trend in epidemiological analysis focuses on ever finer spatial scales in the hopes of gaining a more distinct understanding of infection patterns. In this regard, Stolerman et al [12] investigated the value of X posts (formerly known as Twitter) for COVID-19 early warning on a representative subset of US counties. However, the authors only investigated a comparably small sample of counties (n=97), raising questions with respect to the generalizability of the presented results. Thus, in this study, we extended their investigation on the early warning capabilities of geosocial media data to all US counties.

Furthermore, geosocial media data garnered notable attention across various fields to answer research questions related to mental health or public attitudes, during the COVID-19 pandemic [13]. For instance, researchers investigated how language in Reddit posts reflected real-world pandemic-driven events like lockdowns, revealing significant psychological shifts among users which coincided with tendencies toward decreased analytical thinking [14]. Similarly, Swain et al [15] developed a machine learning model leveraging geosocial media data to predict disruptions in mental well-being caused by the COVID-19 pandemic. Beyond that, researchers explored geosocial media users' attitudes and concerns toward COVID-19 vaccines for the United States and the United Kingdom [16]. They observed that geosocial media derived results correlated broadly with nationwide surveys. In essence, the previous results suggest that geosocial media exchange during the COVID-19 pandemic was likely influenced by real-world public attitudes and even users' mental health. Similarly, a variety of studies indicate that the language used and the topics of interest of geosocial media users vary based on political beliefs [17-19]. This further supports our underlying assumption that differences in political beliefs are likely to be reflected in geosocial media behavior, which could, in turn, correspond to differences in geosocial media's early warning capabilities for COVID-19 cases.

However, even before the surge of the COVID-19 pandemic, researchers observed the emergence of echo chambers when analyzing pro and antivaccination attitudes on Facebook (Meta), which in their opinion might have caused further polarization [20]. In this regard, Howard et al [21] found that X was particularly prone to misinformation and polarizing content compared with professionally produced news during the 2016 presidential election. They even found more misinformation being prevalent in swing states. Such spread of misinformation and emerging political polarization on geosocial media should be of further concern for health experts and policy makers. In particular, since many researchers illustrated that diverging political beliefs can not only influence exchange on geosocial media [17-19], but also real-world individual behavior such as vaccine up-take [22] or the usage of nonpharmaceutical interventions such as mask wearing [23]. This is in line with previous findings [24], which highlight significant variation between individuals with different political beliefs with respect to self-estimated COVID-19 risks, self-reported adherence to COVID-19 health care measures, and expectations on the future course of the pandemic. In addition, researchers observed that US counties that voted in favor of the republican presidential candidate in the 2016 election, experienced up to 3 times higher mortality due to COVID-19 during the winter of 2020 [25].

XSL•FO
RenderX

Hence, in essence it can be assumed that individuals may respond differently on geosocial media to a swiftly politicized epidemic event like the COVID-19 pandemic [26], corresponding to their political beliefs. Evidence further suggests that differences in political beliefs do not only influence online and offline behavior, but they might indeed coincide with higher COVID-19 cases and death rates [25,27,28]. In summary, these results highlight the need to understand and adjust geosocial media based early warning systems with respect to political beliefs. Thus, within the scope of this paper, we seek to answer the following 2 research questions with a particular focus on geosocial media posts:

1. How do the early warning capabilities of geosocial media data change across consecutive epidemiological waves of COVID-19 cases?
2. What differences across US county-level political clusters can be observed with respect to geosocial media's early warning capabilities for COVID-19 cases?

To explore the early warning capabilities of geosocial media data, we determined the correlation between geosocial media posts and COVID-19 cases and the number of days by which signals in geosocial media data preceded actual COVID-19 cases (temporal lag). Furthermore, we specifically examined the temporal lag and the correlation in the context of political clusters based on US county voting data and over the course of 6 consecutive waves of COVID-19 cases.

Methods

Data Collection

We used 2 main data sources in this study. First, we gathered official data on confirmed COVID-19 cases in the United States and we obtained geolocated posts (Tweets) from the geosocial media network X. The time frame for which we collected our data ranges from February 28, 2020, the beginning of the pandemic in the United States, to April 27, 2022, which denotes the end of the first major Omicron wave that began in November 2021 [29]. This time frame covers the main COVID-19 waves, time periods before and after the availability of vaccines, and was selected based on retrospective knowledge on the course of the pandemic. The contiguous United States was chosen as our study area. Furthermore, to gain a more refined understanding of the underlying spatial patterns, we decided to use US counties as our finest spatial analysis resolution, on which we identified politically similar clusters, advancing previous research that was mostly performed on national or state levels.

COVID-19 Case Data

We downloaded officially confirmed COVID-19 cases for the United States in csv format from the not-for-profit public data aggregator USAFacts [30]. The COVID-19 cases csv file contained daily cumulated COVID-19 cases, which we transformed into daily incidence data. In addition, we applied a 14-day moving average to account for possible reporting delays and differing update cycles across states.

Geosocial Media Data

Furthermore, we collected geolocated posts from the geosocial media network X through their official application programming interfaces (APIs) during our investigation time frame [10,12], when academic access for researchers was still available. In particular, we used the Twitter REST and Streaming API access points to gather about 727 million geosocial media posts. The REST API allowed us to retrieve posts from the previous 7 days, with a limit of 450 requests per 15-minute window. In contrast, the Streaming API provided a continuous, real-time stream of posts. For both API endpoints we applied filters to capture only posts containing a geolocation. Thus, each collected geosocial media post includes a geolocation, which can either be the Global Navigation Satellite System position of the device through which the post was shared, or a user-defined location. Furthermore, locations can consist of polygons (eg, city, state level polygons) or point locations. We excluded geosocial media posts with polygon or point geometries that were not located within the county-level geometries, which left us with 242 million posts.

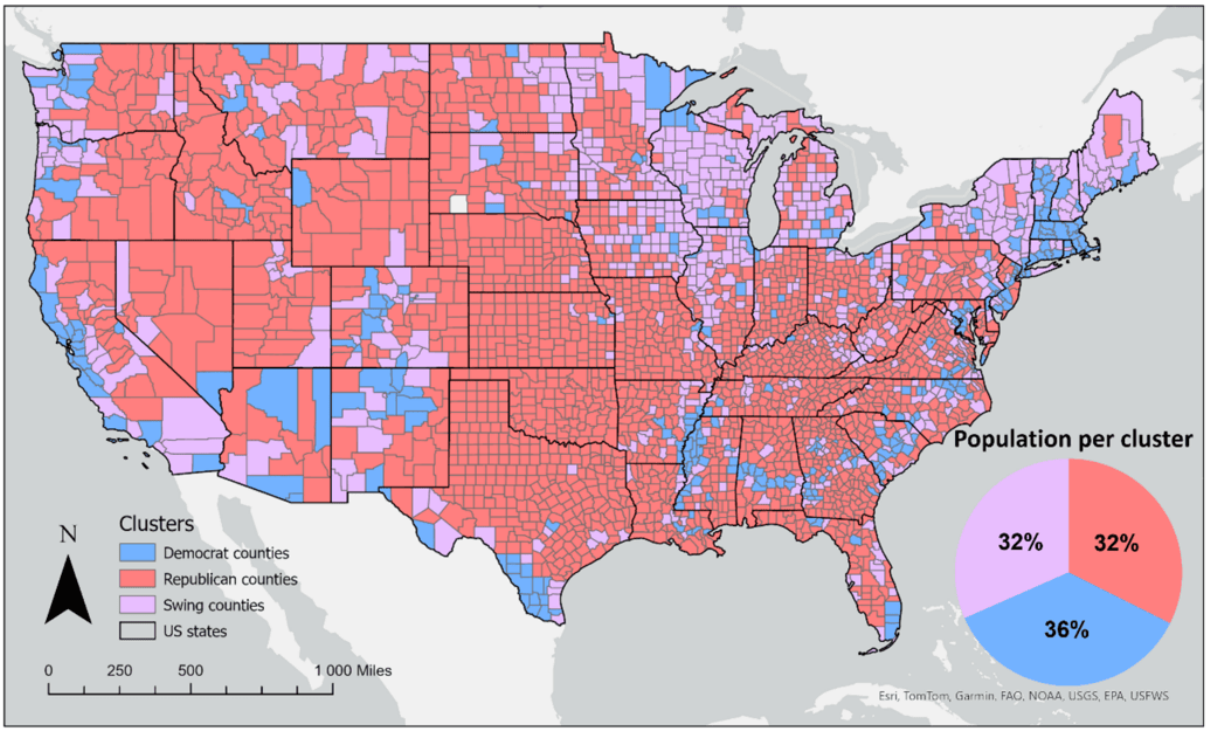
Next, to obtain geosocial media posts that are relevant to the analysis of COVID-19, we performed keyword filtering on the remaining 242 million posts located within county geometries. Therefore, we defined keywords based on the knowledge of geosocial media and health experts, with the goal to properly capture geosocial media trends relevant to the COVID-19 pandemic (Textbox 1). For some keywords only their word stem was used to allow for different variations of the word to be detected.

Textbox 1. Keywords used for relevant post extraction.

COVID-19 keywords:

covid, corona, sarscov, sars-cov, sars, epidemic, pandemic, influenza, virus, viral, infect, spread, 2019-ncov, Delta variant, Omicron, H1N1, H3N2, Wuhan, sickness, transmission, contagio, Illness, outbreak, super spread, incubation, quarantine, lockdown, vaccin, fever, cough, headache, fatigue, body aches, loss of taste, loss of smell, no smell, no taste, respirator, face mask, masks.

After the keyword extraction, the posts were aggregated on US county-level and a 14-day moving average was applied. Finally, to cope with differing amounts of geosocial media posts over time and space, we normalized the amount of relevant filtered geosocial media posts over the amount of all geosocial media posts on county level. In the remainder of this study, we solely used this ratio, that is, the proportion of relevant posts over all posts per county. This allows us to account for spatially clustered population and post density. In total, the semantic filtering procedure left us with 3.3 million relevant posts.



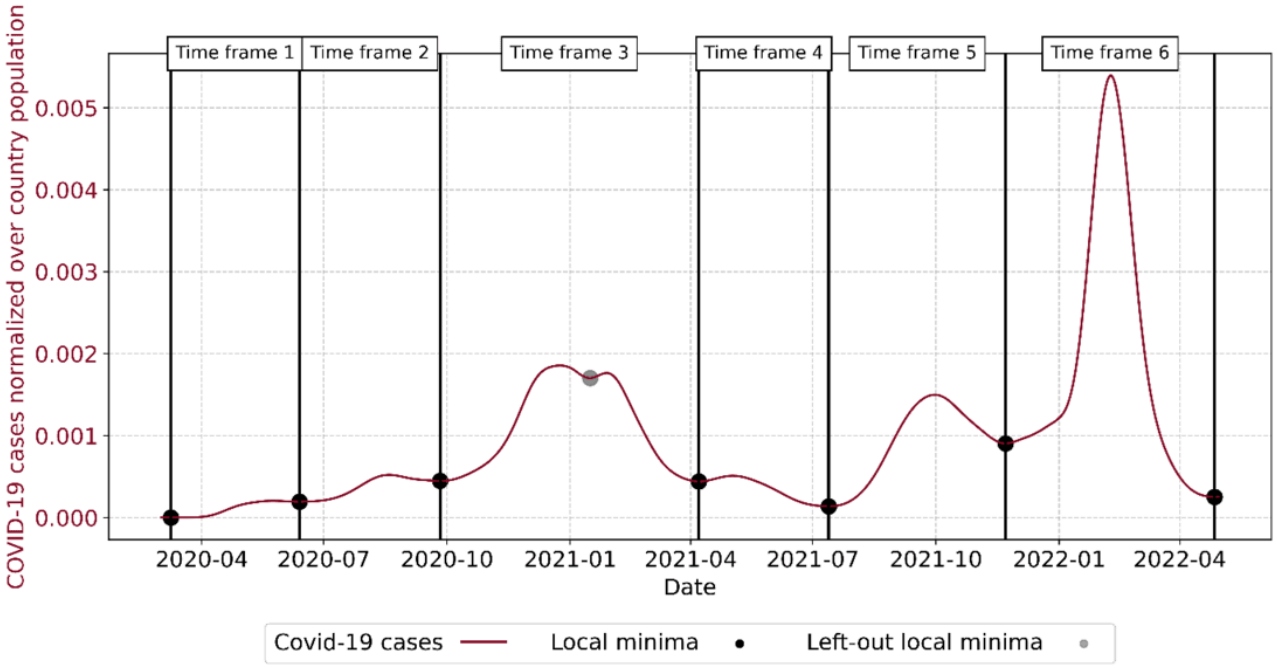
Political Clusters

To examine the differences between the various political beliefs, we based our analysis on voting data from the last 6 US presidential elections. The voting data were obtained from the Harvard Dataverse [31]. We classified US counties into 3

XSL•FO
RenderX

different clusters depending on their historical vote share for either the republican or the democrat party. In the political sciences literature, swing states are traditionally defined through a variety of quantitative and qualitative indicators. However, most of these definitions such as the bellwether status of a state [32], or it being perceived as a battleground [32], are not directly transferable to county-level analysis. Thus, we decided to base the classification into republican, democrat, or swing county clusters, on the so-called flippability of a county [32]. We chose to assess the flippability of a county on its last 6 federal election cycles. Concretely, we classified a county as belonging to a specific party, if said party had won at least 5 consecutive elections in the last 6 elections cycles. All other counties were considered as flipping between political parties and thus classified as swing counties. This division yielded political clusters, each of which representing approximately one third of the US population (Figure 1).

Figure 1. Geospatial distribution of political belief clusters on county level based on the last 6 election cycles.



Defining COVID-19 Waves

We split the COVID-19 cases time series into smaller time frames, to capture individual epidemiological waves. However, there exist multiple approaches to define epidemic waves ranging from statistical methods using, for instance, exponential growth [10,33] or the effective reproduction number R [12,34]. In contrast, other authors tried to identify statistics and guiding principles on the duration of COVID-19 waves based on empirical data [35]. Nevertheless, all these approaches are based on strong assumptions and subjective definitions on what thresholds characterize an epidemic wave. Thus, similarly to [35], we based our definition of COVID-19 waves on a rule-based approach using the local minima on a 21-day moving average of the COVID-19 cases, which was informed through retrospective knowledge on the course of the pandemic.

We defined these time frames based on COVID-19 cases for the entire United States, rather than defining them individually for each political cluster. Furthermore, our procedure yielded 7 different time frames (Figure 2). Nonetheless, these 7 time frames did not accurately reflect all epidemic waves. In particular, the wave ranging roughly from October 2020 to April 2021, was split into 2. As a result, we decided to combine the original time frames 3 and 4 into 1 epidemic wave, which left us with 6 epidemic waves in total. This decision enabled us to capture the epidemic waves more accurately (Figure 2).

XSL•FO
RenderX

Figure 2. COVID-19 case waves for the entire US primarily defined through local minima.

Early Warning Capabilities

Finally, we quantified the early warning capabilities separately for each of the epidemic waves. We defined early warning capabilities twofold: (1) as the Pearson correlation between the time series of COVID-19 related geosocial media posts and COVID-19 cases, and (2) the number of days by which geosocial media posts preceded COVID-19 cases. However, the more important measure for early warning is the correlation between the 2 time series. Put differently, this means that if the temporal lag is high, however a correlation close to zero is present, it is obviously not reasonable to attribute any early warning capabilities to geosocial media data.

Furthermore, to identify the maximal correlation and the corresponding temporal lag, we shifted the geosocial media posts time series between 7 and 42 days into the future to determine the highest possible early warning capabilities. This procedure is repeated for each individual political cluster and epidemic wave, respectively. The decision to investigate a temporal lag between 7 and 42 days into the future was based on previous results [12], in which an early warning model, using, among others, geosocial media data, was able to predict COVID-19 cases between 1 and 6 weeks in advance.

Ethical Considerations

The study was carried out in accordance with the Declaration of Helsinki and with the ethical regulations in place at the Paris Lodron University of Salzburg, and complies with the General Data Protection Regulation legislation of the European Union. We only used publicly available data, which were collected in accordance with the terms of service of the respective geosocial media platform X at the time of data collection. Furthermore, no identifiable information was revealed in this study. Specifically, the user-provided geographic locations and semantic content were spatially aggregated to ensure user privacy and anonymity. Thus, we did not need to seek ethical approval from our institution for this study.

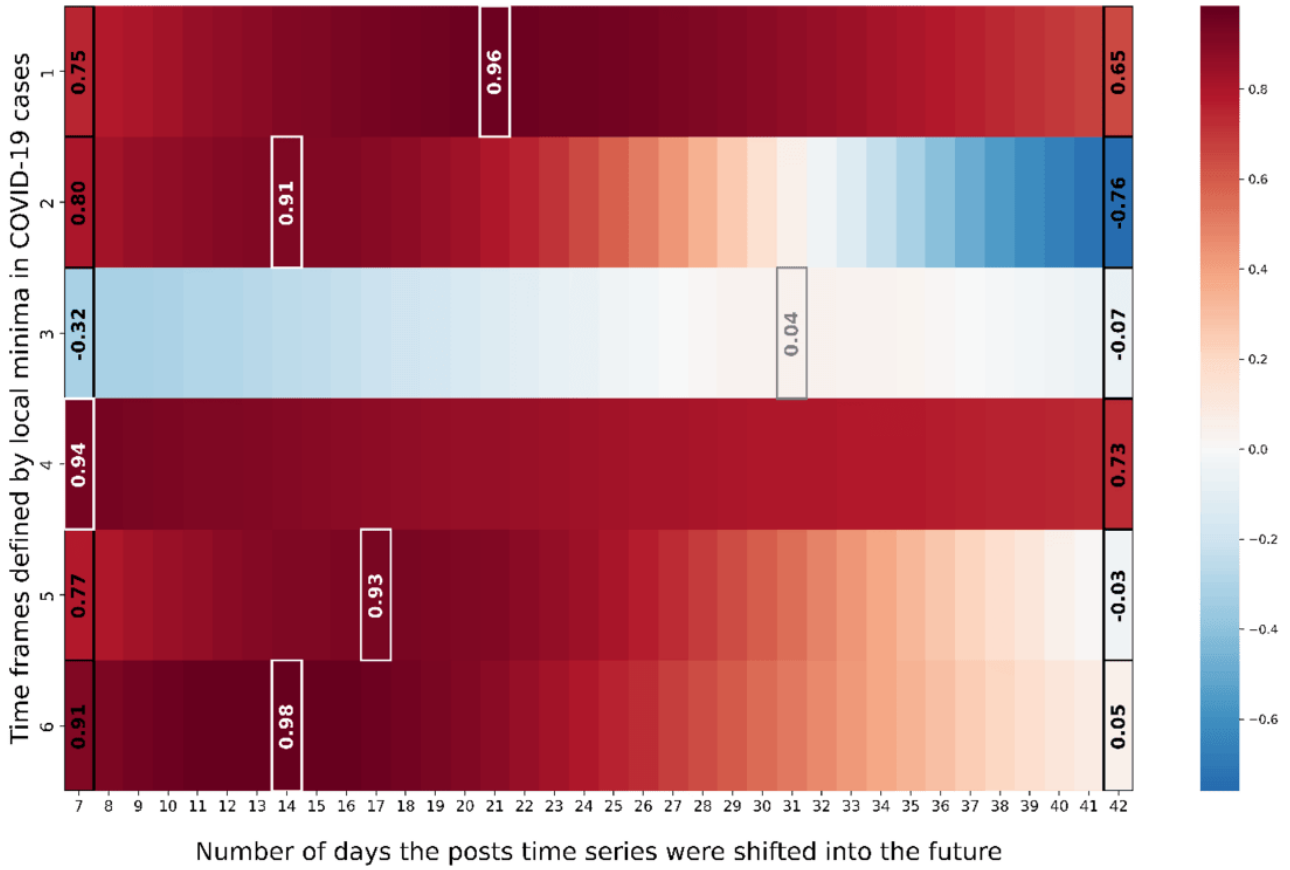
Results

Democrat Counties

Figure 3 depicts the Pearson correlation for different temporal lags between the time series of COVID-19 cases and geosocial media posts in democrat counties. In particular, the y-axis represents the individual waves of COVID-19 cases as introduced in Figure 2, while the x-axis denotes the number of days the posts time series was shifted into the future. The coloring of individual windows reflects the Pearson correlation between COVID-19 cases and the shifted posts time series. Furthermore, Figure 4 illustrates the corresponding COVID-19 cases, the post time series and the post time series shifted by the correlation maximizing temporal lag for each individual epidemic wave.

XSL•FO
RenderX

Figure 3. Depicting the Pearson correlation between COVID-19 cases and geosocial media post time series for each epidemiological wave when stepwise shifting the geosocial media post time series into the future for democrat counties.



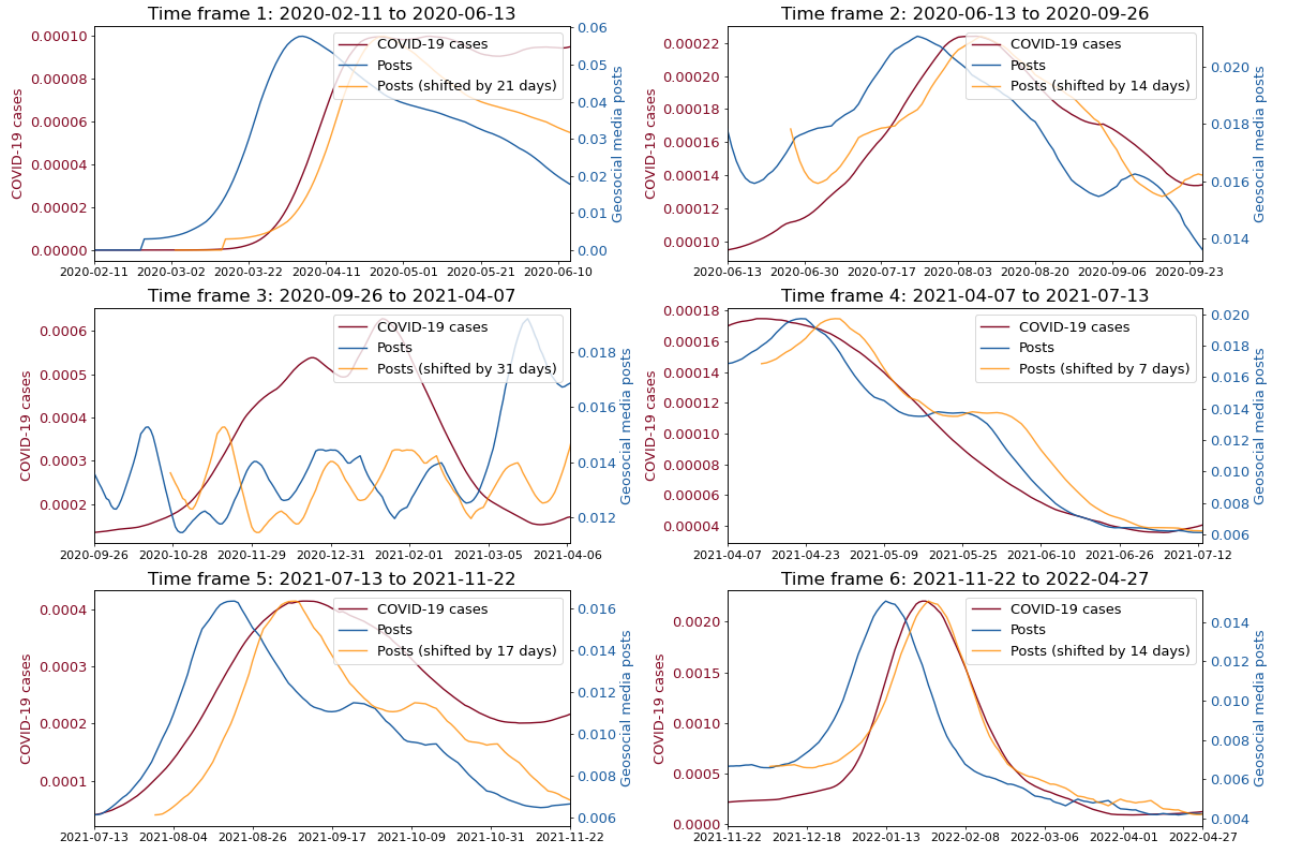


Figure 4. Depicting COVID-19 cases and the geosocial media posts time series and the shifted geosocial media posts time series across individual epidemic waves for democrat counties.

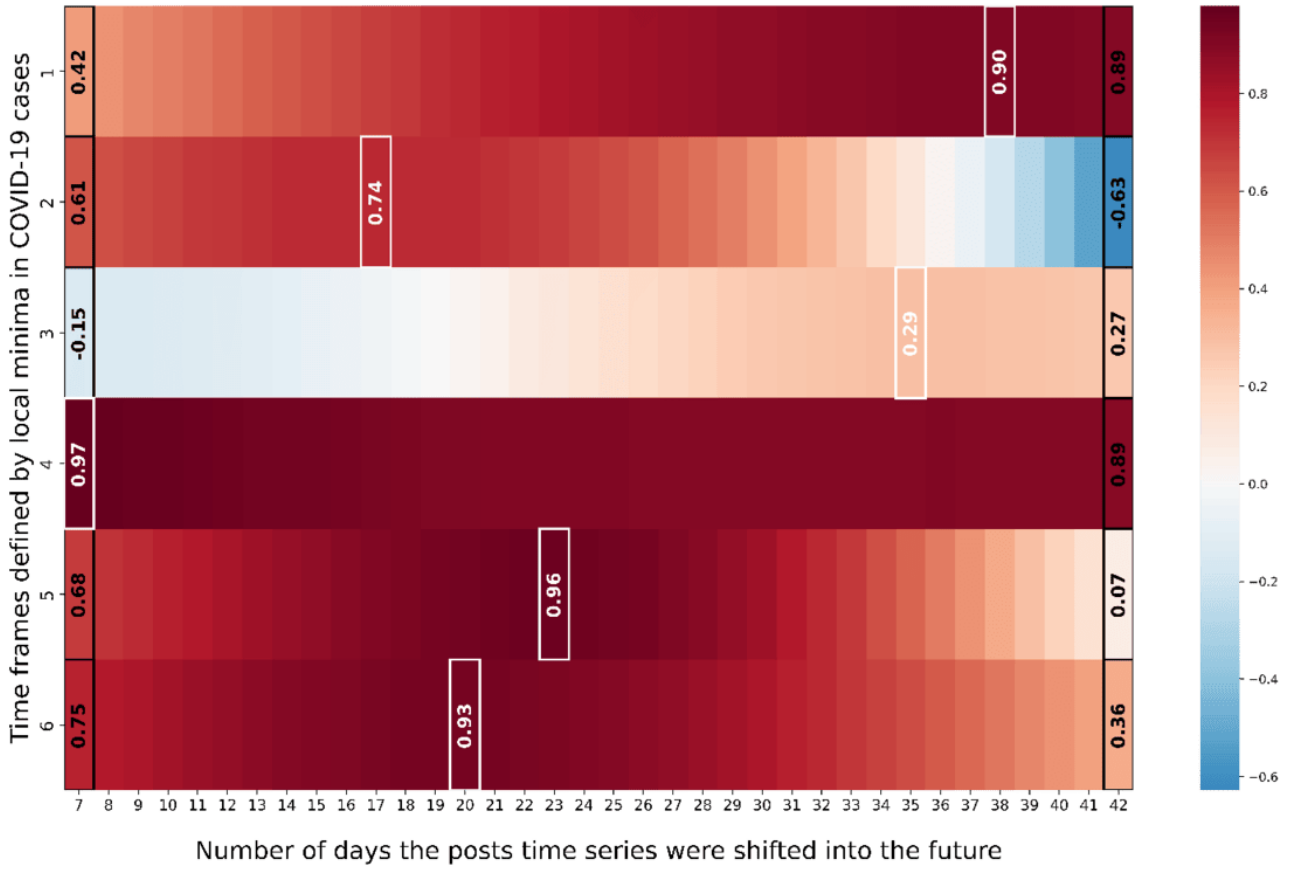

XSL•FO
RenderX

The results for democrat counties in Figure 3 indicate the highest Pearson correlations between posts and COVID-19 cases time series in 5 out of 6 epidemic waves, for a shift of 7 to 21 days (time frames 1, 2 and 4-6). For the same 5-time frames, the Pearson correlations ranged between 0.91 to 0.98. Furthermore, Figures 3 and 4 suggest that only for time frames 1, 2 and 4-6, geosocial media data exhibited actual early warning capabilities. For these time frames, signals in COVID-19 cases were clearly preceded by signals in X data, while for time frame 3 no clear early warning signal in geosocial media data was apparent. Nevertheless, in the beginning of the pandemic (time frames 1 and 2) geosocial media posts showcased a clear increase up to 21 (time frame 1) and 14 days (time frame 2) ahead increases in COVID-19 infections, with Pearson correlations of 0.96 and 0.91. In addition, the COVID-19 wave from mid of July 2021 to the end of November 2021 (time frame 5) was reflected in geosocial media posts up to 17 days earlier than an increase in COVID-19 cases, with a Pearson correlation of 0.93. Also, the Omicron wave (time frame 6) starting in mid of November 2021 [29] was accurately reflected 14 days in advance in the geosocial media time series (Pearson correlation of 0.98). Beyond that, Figure 4 clearly illustrates that the ratio of geosocial media posts related to COVID-19 decreased significantly over the course of the pandemic. Specifically, the percentage of relevant geosocial media posts gradually decreased from 5.7% at its peak in the first time frame, to 1.5% in the last time frame.

Republican Counties

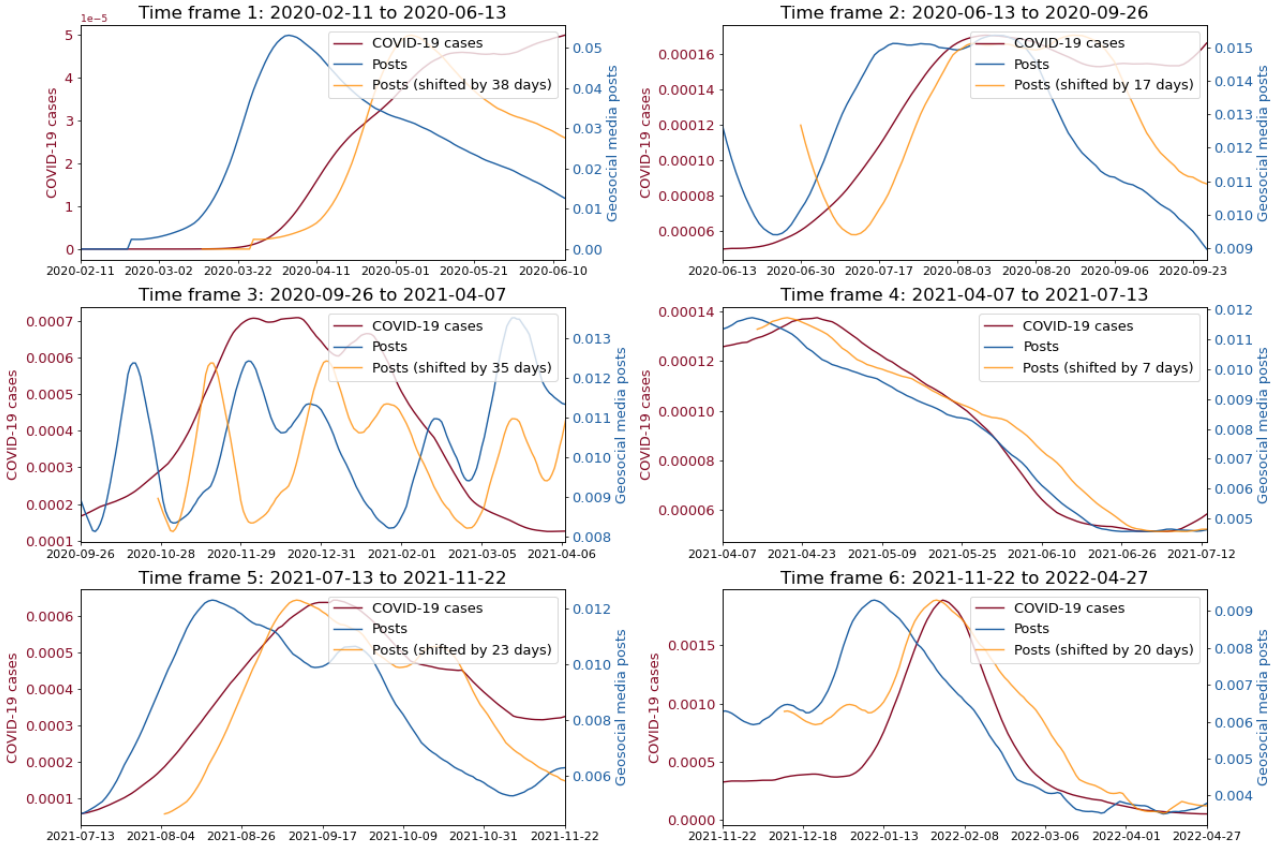

Figure 5 illustrates for the republican counties that in 5 out of 6 time frames the post time series exhibited the highest Pearson correlation with the COVID-19 cases 7 to 38 days ahead of time (time frames 1, 2, and 4-6). Furthermore, for these time frames the Pearson correlations between posts shifted 7 to 38 days into the future and COVID-19 cases were between 0.74 and 0.97. Furthermore, Figure 6 showcases that for republican counties, early warning signals in geosocial media posts could be observed for time frames 1, 2 and 4-6. Similarly to the democrat county cluster, the COVID-19 cases wave in time frame 3 was not captured in advance by the geosocial media time series. The fact that all time frames besides time frame 3, lend themselves for early warning is also consistent with the results for the democrat counties. Furthermore, it appears that in the republican counties, geosocial media data preceded COVID-19 cases time series a few days more in advance. On average over all 5 time frames for which we attest early warning capabilities (time frames 1, 2, and 4-6), the mean temporal lag in democrat counties is 14.6 days (average correlation 0.94) and for 21 days republican counties (average correlation 0.9). Furthermore, it appears that the ratio of relevant posts decreased over time for republican counties from roughly about 5.3% to 0.9%.

Figure 5. Depicting the Pearson correlation between COVID-19 cases and geosocial media post time series for each epidemiological wave when stepwise shifting the geosocial media post time series into the future for republican counties.

XSL•FO
RenderX

Figure 6. Depicting COVID-19 cases and the geosocial media posts time series and the shifted geosocial media posts time series across individual epidemic waves for republican counties.

Swing Counties

Figure 7 illustrates for swing counties that shifting the posts time series between 7 and 37 days into the future achieved the highest correlation for all time frames. Furthermore, for all time frames the maximal Pearson correlations between geosocial media posts and COVID-19 cases ranged between 0.52 and 0.96. Beyond that, Figure 8 shows that the time frames 1, 2 and 4-6 exhibited clear early warning signals in geosocial media data ahead increases in COVID-19 cases. Similarly to the republican and democrat counties, the COVID-19 wave in time frame 3 was not clearly captured in advance by geosocial media data. However, similar, to republican counties, Figure 8 showcases for swing counties that there actually existed a signal in geosocial media data which is in line with the COVID-19 data in time frame 3. Nevertheless, the actual early warning capabilities are still limited due to noise in the signal which coincides with the COVID-19 infection of former President Donald Trump. Overall, the posts time series preceded COVID-19 cases in swing counties across all time frames, excluding the third, on average by 24.2 days. Also, the intensity with which geosocial media data appears to precede COVID-19 waves clearly decreased for swing counties over the course of the pandemic (from 5.6% to 1.1%).

Discussion

Principal Findings

The results of this study highlight how a deeper understanding of the relationship between COVID-19–related geosocial media data and confirmed COVID-19 cases, across politically distinct geographies, may help improve epidemiological early warning systems. Specifically, our analysis confirmed and expanded previous findings on the use of geosocial media posts as early indicators of disease activity [8-10,12]. However, we observed strong differences in the early warning capability of geosocial media data across different epidemiological waves. For example, geosocial media data were unable to reliably anticipate the third major COVID-19 wave, September 2020 to April 10, 2021 (time frame 3), across all political clusters. After significantly high COVID-19–related engagement on geosocial media in the first wave, it appears that the geosocial media signal lost some of its sensitivity in the third wave. The only event clearly detectable in COVID-19–related geosocial media posts in the third time frame is the COVID-19 infection of the former President Donald Trump in October 2020. The significance of this event might have reduced the sensitivity of the geosocial media users toward an increase in COVID-19 symptoms and infections. The reaction signal to this event was particularly visible in the republican and swing county clusters, while the democrat counties only registered a minor increase in geosocial media posts coinciding with the COVID-19 infection of President Trump. This further highlights how susceptible geosocial media data can be to politically charged trending topics and how these topics of interest might differ across political clusters. This is also in line with previous findings that the topics geosocial media users engage with and the language they use can differ depending on political beliefs [17-19]. Thus, we hypothesize that it might be key to identify different sets of keywords related to political beliefs and resulting trending topics, to capture geosocial media signals more accurately across political clusters. Therefore, future research should explore the influence of different geosocial media topics on early warning capabilities across political clusters and how such topics might change over time.

Furthermore, the findings of this study illustrate differences in the early warning capabilities of geosocial media posts for COVID-19 cases across counties with diverging political beliefs. This is particularly true for the number of days that geosocial media posts precede COVID-19 cases (temporal lag) and the Pearson correlation between these 2 time series for republican and democrat counties. For instance, geosocial media posts appear to anticipate COVID-19 cases in republican counties (21 days) on average 6.4 days earlier than in democrat counties (14.6 days). This difference in temporal lag might partly be caused by varying population densities between democrat and republican counties. In less densely populated republican counties [36], infection transmission might be slower [37], which could lead to a higher temporal lag between the onset of COVID-19 symptoms being observed and shared on geosocial media, to the eventual peak of infections in that region. However, it remains beyond the scope of this study to substantiate the actual underlying mechanisms which might cause these observed differences in early warning capability between political clusters. Despite that, the results of this study clearly emphasize the need to account for political beliefs in epidemiological early warning systems using geosocial media data. Nevertheless, the precise methodology to integrate political beliefs into real-time geosocial media-based early warning models remains the subject of future research.

The psychological effects of public health measures, such as lockdowns, might offer another explanation for the observed differences in early warning capabilities of geosocial media data across political clusters. These effects may be connected to the fact that public health measures were implemented and suspended at different points in time across political administrative areas. In this regard, Pettersen et al [38] associated more stringent public health and quarantine measures with increased mental distress in adults in Norway. Similarly, Ferwana and Varshney [39] observed a significant increase in visits to mental health facilities during the 2020 lockdown periods in the United States. While Ashokkumar and Pennebaker [14] even reported drops in analytical thinking and shifts in the emotional states of Reddit users coinciding with the start of lockdowns. Hence, it might be the case that the varying timing of public health measures across political regions caused various psychological effects, manifesting in changes of geosocial media behavior. However, our findings do not sufficiently verify this hypothesis. Although numerous studies have explored the psychological effects of public health measures, future research should focus on how these effects might influence the early warning capabilities of geosocial media data across the political spectrum.

In addition, we also found a clear decrease in the number of days with which geosocial media posts preceded COVID-19 cases and in the strength of the geosocial media post signal over time. Interestingly, yet to be explained, the decrease in temporal lag appears to be less pronounced in republican and swing counties. Nonetheless, this overall phenomenon might be caused by some sort of geosocial media and emotional COVID-19 fatigue. The association between self-reported depression symptoms and geosocial media usage [40], alongside potential factors contributing to social media fatigue [41-43] have already been explored in the context of the COVID-19 pandemic. For instance, recent findings by Li et al [43] indicate a direct relationship between social media overload during the COVID-19 pandemic and increased anxiety. Similarly, Sun and Lee [44] observe that COVID-19 information overload on social media directly contributes to fatigue toward pandemic related messages. Nevertheless, it remains beyond the scope of this study to substantiate whether the observed decreasing strength of the geosocial media post signal and temporal lag are robust and attributable to some form of geosocial media or COVID-19 fatigue. However, based on our observations, we advise caution, as the epidemiological early warning capabilities of geosocial media appear to change over time and depending on prevailing political beliefs. In this regard, it remains the task of future research to develop geosocial media-based early warning approaches, which can account for decreasing signal strength over time.

XSL•FO
RenderX

Furthermore, Howard et al [21] observed varying levels of misinformation and thus topics of interest, across states with different political beliefs. Interestingly, they found the highest rates of misinformation occurring in swing states. This is particularly noteworthy, as we found geosocial media data to be highly capable for early epidemiological warning in swing counties. Specifically, the average temporal lag of 24.2 days over all time frames in which we observed the highest early warning capabilities for swing counties, while mostly achieving high correlations (average correlation over all time frames with early warning capabilities 0.88). Thus, concluding from Howard et al [21] and our findings, it appears that it might not be the quality or factual correctness of the shared information on geosocial media that warrants its value for early warning purposes. Nevertheless, future research needs to further validate these findings in the context of different countries and their political ramifications as they might influence the relevance of shared information quality and factual correctness for epidemiological early warning capability.

Data and Methods

We acknowledge that using a simple linear correlation measure might not always reflect the actual similarity between time series accurately. However, in preliminary analysis we also used different nonlinear correlation measures, which yielded only neglectable differences in the actual results. In addition, we also tested more advanced time series matching algorithms such as dynamic time warping [45], the Fréchet distance [46], or mutual information [47]. Nevertheless, neither nonlinear correlation measures nor more advanced comparison algorithms outperformed conventional linear correlation measures for most of our analyses. We evaluated the performance of these different methods in their ability to match the peaks and onsets of geosocial media signals and COVID-19 cases. Nonetheless, we acknowledge that the alignment of peaks and onsets is not always feasible, as the time it takes from the onset to the peak may vary between geosocial media signals and COVID-19 cases. As a result, for some epidemic waves the determined temporal lag might not reflect the actual real-world early warning capabilities of geosocial media data. Despite that, our main objective in this study was not to assess the exact temporal lag and correlations, but rather to provide an algorithmic way to compare the early warning capabilities of geosocial media data across political clusters.

In addition, there is a need to discuss the definition of epidemiological waves based on COVID-19 cases of the entire United States as one might argue that this decision might potentially have caused the observed variations in the number of days and the correlation between the geosocial media and the COVID-19 cases time series. The reason for this is that the COVID-19 waves can have different starting points and intensities across states [48] and as our results show also across political clusters (Figures 4, 6, and 8). Therefore, it might appear reasonable to assume that variation in the starting points and intensities caused the underlying observed differences in temporal lag and correlation between geosocial media posts and COVID-19 cases across political clusters. However, upon testing this hypothesis by defining COVID-19 waves individually for each political cluster, the fundamental results of our study remained unchanged. Although minor discrepancies were present in the temporal lag (primarily ranging from 1-2 days) and the correlations between COVID-19 cases and geosocial media posts, their differences persisted across political clusters and time frames in a similar manner. For example, republican counties still exhibited on average a higher temporal lag than democratic counties and the decrease in geosocial media signals was also still prevalent across political clusters.

In addition, it is important to consider the choice of keywords used for our analysis, as they strongly influence the observed results. One might argue that some keywords relevant to the discourse related to the COVID-19 pandemic were left out. However, in this analysis we mainly focused on gathering less polarized keywords, topics, and hashtags. The reason for this is that certain words, topics and hashtags were predominantly used by 1 political faction [17,18], which might indeed introduce bias into the final comparison between early warning capabilities across political clusters from the start. Concretely, keywords used predominantly in republican counties and less in democrat counties might directly influence differences in early warning capability across political clusters. Therefore, we decided to use a condensed set of keywords, which was to our knowledge mostly not inherently politically charged or biased.

Furthermore, we acknowledge that some keywords which we used in the semantic filtering process of the geosocial media posts, might not be only COVID-19 specific. However, we argue that for most words there exists a baseline signal of how often these words are being used. Therefore, our underlying assumption is that a real-world epidemiological event causes a significant spike in the usage of relevant keywords. Indeed, our results confirmed this assumption. We observed a baseline fluctuation in geosocial media posts and significant spikes in filtered posts, which in most cases preceded COVID-19 cases.

We also tried to improve the semantic filtering by leveraging machine learning approaches such as BERTopic or Latent Dirichlet Allocation [49,50]. However, due to performance issues with our large dataset (600+ GB) and based on the insufficient results for subsample experiments, we decided to stick to traditional keyword filtering. Nevertheless, in future work large language models [51] might be a possibility to improve the process of identifying relevant geosocial media posts.

Limitations

The main limitation of this study stems from its retrospective nature. Our findings, while insightful for the past pandemic, may not be directly transferable to future epidemiological events. This limitation is partly due to the unpredictable nature of political polarization. Specifically, it is inherently difficult to predict whether a topic will become politically charged and, as a result, be discussed differently on social media across geographies with diverging political beliefs. In addition, social media behavior itself is influenced by various dynamic factors, for instance platform algorithms [52] or changing governance structures, which affect public engagement [53], all of which may differ significantly across social media platforms, future epidemiological events, and national borders. Although our study revealed differences in the epidemiological early warning

XSL•FO
RenderX

capabilities of geosocial media data across US county-level political clusters, these results should be treated with caution when considering future-use cases.

Conclusion

Our results confirmed the findings of previous research [9,10,12], demonstrating that geosocial media data can improve epidemiological early warning for consecutive waves of COVID-19 cases. In addition, we expand the existing literature by showing that the early warning capabilities of geosocial media data vary across US county clusters with differing political beliefs. For instance, geosocial media posts in republican counties (21 days) tend to precede increases in COVID-19 cases on average about 6.4 days earlier than in democrat counties (14.6 days). We hypothesize that this discrepancy in temporal lag between the geosocial media signal and the COVID-19 cases may stem from differences in the adoption of public health measures or population density variations across regions. In addition, we observed that the early warning capabilities of geosocial media data can be mitigated due to its susceptibility to a shift in trending topics and a decrease in signal strength over time.

Based on our findings, we would recommend that policy makers and researchers enhance and further investigate real-time geosocial media monitoring capabilities to improve epidemiological early warning systems. In addition, our findings suggest that it could be particularly beneficial for such systems to account for political beliefs prevalent across finer spatial scales such as county-level, given their potential to impact the early warning capabilities of geosocial media signals. Furthermore, since our results clearly highlight the value of geosocial media data for epidemiological early warning, we strongly encourage social media companies to grant researchers access to their data. Furthermore, future research should examine the early warning capabilities of different geosocial media topics specific to regional political beliefs and assess the transferability of our findings to other countries with different political environments. Furthermore, investigating the role of political communication strategies and potential improvements to social media algorithms to mitigate political polarization could enhance our understanding of how geosocial media data can be leveraged for future epidemiological events.

Abstract

Background: During the COVID-19 pandemic, health experts used social media platforms to share information and advocate for policies. Many of them faced online abuse, which some reported took a toll on their mental health and well-being. Variation in the impacts of online abuse on mental health, well-being, and professional efficacy suggest that health communicators may differ in their coping strategies and ultimately their resilience to such abuse.

Objective: We aimed to explore the impacts of online abuse on health communicators' mental health and well-being as well as their emotion- and problem-focused coping strategies.

Methods: We recruited health communicators (public health officials, medical practitioners, and university-based researchers) in Canada who engaged in professional online communication during the COVID-19 pandemic. In phase 1, semistructured interviews were conducted with 35 health communicators. In phase 2, online questionnaires were completed by 34 individuals before participating in workshops. Purposive recruitment resulted in significant inclusion of those who self-identified as racialized or women. Interview and workshop data were subjected to inductive and deductive coding techniques to generate themes. Descriptive statistics were calculated for selected questionnaire questions.

Results: In total, 94% (33/35) of interviewees and 82% (28/34) of questionnaire respondents reported experiencing online abuse during the study period (2020-2022). Most health communicators mentioned facing an emotional and psychological toll, including symptoms of depression and anxiety. Racialized and women health communicators faced abuse that emphasized their ethnicity, gender identity, and physical appearance. Health communicators' most common emotion-focused coping strategies were withdrawing from social media platforms, avoiding social media platforms altogether, and accepting online abuse as unavoidable. Common problem-focused coping strategies included blocking or unfriending hostile accounts, changing online behavior, formal help-seeking, and seeking peer support. Due to the impacts of online abuse on participants' mental health and well-being, 41% (14/34) of the questionnaire respondents seriously contemplated quitting health communication, while 53% (18/34) reduced or suspended their online presence. Our findings suggest that health communicators who used problem-focused coping strategies were more likely to remain active online, demonstrating significant professional resilience.

Conclusions: Although health communicators in our study implemented various emotion- and problem-focused coping strategies, they still faced challenges in dealing with the impacts of online abuse. Our findings reveal the limitations of individual coping strategies, suggesting the need for effective formal organizational policies to support those who receive online abuse and to sanction those who perpetrate it. Organizational policies could improve long-term outcomes for health communicators' mental health and well-being by mitigating online abuse and supporting its targets. Such policies would bolster professional resilience, ensuring that important health information can still reach the public and is not silenced by online abuse. More research is needed to determine whether gender, race, or other factors shape coping strategies and their effectiveness.

mental health; online harassment; online abuse; coping strategies; resilience; social media; online advocacy; public health communication; health communication

Introduction

Background

From the start of the COVID-19 pandemic, public health officials, medical practitioners, university-based researchers, health journalists, and other health experts played a crucial role in shaping public opinions and behaviors. To inform publics and counter poor-quality information, many health experts increased their use of social media platforms: frontline health care workers creating TikTok videos [1], medical professionals countering misinformation on Twitter [2], and physicians and researchers posting on Facebook, Instagram, and Twitter [3,4]. These health communicators could be considered an emergent community of practice, meaning they encountered many similar opportunities and challenges of engaging audiences through social media platforms.

Many health communicators were exposed to online harassment and abuse, ranging from trivial criticisms to sexual harassment and violent threats [5,6]. This abuse was faced by those communicating as individuals or on behalf of institutions. Health communicators were typically unprepared for the abuse that often follows online advocacy [7], which was exacerbated by a lack of existing institutional protections and supports [7,8].

Exposure to Online Abuse

In a survey conducted from February 2019 to March 2019, 23% of 464 physicians in the United States reported being personally attacked on social media, primarily for advocacy on topics such as vaccines, gun control, and abortion [9]. Research suggests that the online harassment experienced by health communicators worsened during the COVID-19 pandemic [10,11]. In a 2022 survey of 359 physicians, biomedical scientists, and trainees in the United States, 228 (64%) reported harassment on social media related to comments they had made about the COVID-19 pandemic [12]. Similarly, more than two-thirds of 321 scientists responding to a *Nature* survey in 2021, predominantly located in the United States, the United Kingdom, and Germany, reported negative experiences because of their media interviews or social media comments regarding COVID-19 [10]. In total, 22% of these respondents had received threats of physical or sexual violence, and 15% had received death threats [10]. Threats of violence illustrate that online abuse is not merely confined to the internet [13]. Escalating violence against health care workers in Canada during the COVID-19 pandemic prompted the Canadian Medical Association to call for legislation in 2021 that would protect health care workers from aggressive patients and protesters, both online *and* in-person [14].

Forms of online abuse may differ with individuals' gender identity, race or ethnicity, professional role, and other factors. For instance, women health communicators and journalists have faced more gendered or sexualized abuse than men [6,9,15].

Impacts of Online Abuse

Research suggests that online abuse can have serious negative consequences for health communicators' mental health and well-being: individuals who have experienced online harassment consistently report emotional distress and fear [2,9]. In a prepandemic survey, 62.4% (63/101) of prominent medical science communicators reported some negative mental health impacts, including depression, anxiety, and stress because of public engagement [6]. While most mental health impacts they reported were minor, 15% of them reported considerable or significant mental health ramifications [6]. Mental health consequences of online abuse can be disproportionately experienced due to gender, race or ethnicity, and other sociodemographic factors [15]. Throughout the COVID-19 pandemic, many health communicators have spoken out about the toll that negative comments and personal attacks have taken on their mental health [5,11]. In the *Nature* survey, more than 40% of 321 scientists reported experiencing emotional or psychological distress after commenting about the COVID-19 pandemic in traditional media interviews or on social media [10].

Some health communicators have expressed a desire to reduce or stop their online advocacy [6,10,12]. Thus, online abuse and its mental health consequences may undermine individuals' professional capacity, reducing the amount of engagement within the communication sector. If certain voices (eg, women and racialized individuals) are pushed out [16], then the diversity of perspectives within this sector will be in jeopardy.

Coping and Other Responses to Online Abuse

Variation in the impacts of online abuse on mental health, well-being, and professional efficacy suggests that health communicators differed in their coping strategies and ultimately their resilience to such abuse. A person who has experienced harassment will tend to adopt one or more strategies to "cope with it" [16]. Lazarus and Folkman [17] developed a seminal model to understand coping as either emotion- or problem-focused. Emotion-focused coping strategies help regulate emotional responses to a stressful situation, whereas problem-focused coping strategies aim to manage or alter the situation itself [17]. The effectiveness of emotion- and problem-focused coping strategies has been debated, but those who rely predominantly on emotion-focused coping strategies report significant negative emotions and poor mental health outcomes, such as depression [18].

Research on the coping strategies used by individuals who receive online abuse has primarily been conducted with journalists, scholars, and students [16,18-20], rather than health communicators. Many studies have further stratified emotion- and problem-focused coping strategies. For example, Scarduzio et al [21] put forth 11 "types" of emotion-focused strategies (eg, ignoring negative comments) and 5 "types" of

XSL•FO
RenderX

problem-focused strategies (eg, blocking hostile users) used by university students in response to online sexual harassment. In this study, we leveraged the model developed by Lazarus and Folkman as well as the examples of digital coping strategies given by Scarduzio et al to examine how health communicators responded to online abuse.

Objectives

Despite the broad adoption of social media by health care providers, scientists, and public health officials and the increasing recognition of online abuse they have received, no study has focused on the mental health consequences of *online* harassment for health communicators during the COVID-19 pandemic. Thus, our study aimed to explore (1) the impacts of online abuse on health communicators' mental health and well-being during the COVID-19 pandemic and (2) the emotion- and problem-focused coping strategies health communicators used to manage online abuse.

Methods

Study Design

This study is part of a larger participatory action research project on an emergent community of practice of health communicators. Relationships with health communicators were developed through direct outreach and through a partnership with ScienceUpFirst, a Canadian initiative that works with science and health experts to address misinformation. We used mixed methods, including semistructured interviews, an online questionnaire, and 2 workshops to examine the impacts of online abuse on Canadian health communicators during the COVID-19 pandemic.

Participant Recruitment

Health communicators for the larger participatory action research project were purposively recruited in 2 phases, emphasizing significant inclusion of those who self-identified as women or racialized. We use the term "racialized" rather than "visible minority groups" or the terms "Black," "Indigenous," and "people of color," following recommendations to use the former term by the Canadian government [22] and academics [23], arguing that race "does not exist as a biological concept to distinguish between human beings, but that social processes of racialization are inherently linked to major forms of historical, social, economic, and cultural oppression, including slavery and colonialism" [23].

During the first phase, research team members monitored traditional and social media platforms to identify people in Canada who were actively discussing public health measures online during the COVID-19 pandemic. Team members contacted a subset of these individuals by email, seeking participation from health communicators of diverse gender identities, ethnicities, and professional roles (eg, public health officials, health care professionals, university-based or civil society health experts, and health journalists). Health communicators who replied (N=35) were invited to participate in a virtual one-on-one semistructured interview, after informed consent was obtained.

During the second phase, team members recruited health communicators to participate in 2 workshops. Participants were recruited through #ScienceUpFirst affiliate groups and the authors' professional networks, seeking similar forms of diversity to the first phase. Journalists were intentionally excluded from the second phase because exploratory conversations with journalists and other health communicators suggested that combining these groups might put participants in awkward professional predicaments and because there has already been extensive research on online abuse of journalists [15,19,24]. In this phase, health communicators (N=34) first completed an online questionnaire to collect data on sociodemographic characteristics, communication activities, and experiences of harassment. Then, they participated in 1 of 2 virtual small-group 2-hour workshops. Observations from these workshops were taken from the research team members' notes because no audio-recordings or transcripts of the discussions were made.

Data Collection and Analysis

Quantitative Data

Given that there are no validated scales for online abuse of individuals in their professional capacities, we developed a questionnaire by drawing on existing questionnaires [13], including one previously created by the research team members [25] and another created by Ipsos to survey journalists' experiences of online harm [24]. Alongside the frequency, causes, and sources of online abuse, our questionnaire assessed how participants responded to online harm and how they changed their personal and professional work as health communicators due to online abuse. Simple descriptive statistics were calculated for specific questions using Microsoft Excel. All data were anonymized to protect participant confidentiality and were stored in a secure electronic database.

Qualitative Data

One-on-one interviews (N=35) were conducted by a research team member and recorded over Zoom (Zoom Communications, Inc) between December 2021 and June 2023. Each interview lasted between 40 and 90 minutes. A semistructured interview guide was used to conduct the interviews, which allowed researchers to compare participants' responses to set questions within the guide and explore other insights based on responses. Questions addressed issues, including the form and frequency of online abuse, professional and mental health impacts, and the online and offline actions that individuals took to respond to abuse. Zoom audio-recordings were transcribed verbatim.

For the first round of coding, our principal researcher created an initial list of deductive codes from literature on online harassment of politicians and journalists [16,25]. Three team members then coded approximately 15% (5/35) of the interview transcripts using this list, meeting regularly to discuss whether deductive codes and their definitions should be modified and whether new inductive codes should be added to the list. A revised codebook was created, and the remaining interview transcripts were independently coded using ATLAS.ti (Lumivero) software. Team members continued to discuss

XSL•FO
RenderX

coding during this process to ensure their shared fidelity to the revised codebook.

A second round of coding was undertaken to examine interview data about health communicators' mental health and well-being in more detail. One team member coded all interview excerpts that had been tagged with the "Impact: Mental health" code during the first round of coding. Inductive coding techniques were used to generate themes around mental health and resilience. Deductive coding techniques were used to identify emotion- and problem-focused coping strategies from the model developed by Lazarus and Folkman [17] and the study by Scarduzio et al [21]. Patterns across the excerpts were noted, and our team met 4 times to collectively categorize and interpret themes.

Ethical Considerations

This study was reviewed and approved by the University of British Columbia Behavioural Research Ethics Board (H21-01503 and #H22-01816). For one-on-one interviews, all participants received a consent statement outlining the study, potential risks and benefits, and measures to protect their personal information. The interviewer reviewed these details at the start of the interview and obtained verbal consent before proceeding. For individuals who completed surveys and participated in workshops, all participants signed a consent form that described the study, potential risks and benefits, and measures to protect their personal information.

Discussing online abuse can be difficult. Both the consent statement and consent form emphasized that participation was entirely voluntary, that individuals could stop participating in the interview or focus group at any time, and that they could withdraw from the study at any point. During interviews, if a participant expressed or displayed discomfort, the interviewer offered to pause, end the interview, or move to another question. For workshops, all participants received a community guidelines document in advance to ensure that group discussions were conducted safely and inclusively.

Data from this project are stored on password-protected hard drives and University of British Columbia–managed cloud storage, accessible only to core research team members registered as part of our research ethics board certification.

Results

Participant Characteristics

Table 1 outlines the sociodemographic characteristics of the interviewees (N=35) and questionnaire respondents (N=34). Most participants were living and working in either British Columbia or Ontario, Canada's 2 most populous English-speaking provinces. More women participated in both phases of this study than men, but both phases had an equal number of self-identified racialized and White participants.

[a]While several participants belong to more than one category (eg, medical professional *and* university-based expert), we categorized participants based on their *primary* professional role.

[b]Employed by a public health agency, provincial government, or federal government.

[c]Employed by a nonprofit organization, research institute, community health center, science center, or self-employed.

Impacts of Online Harassment on Health Communicators' Mental Health and Well-Being

In the first phase, 94% (33/35) of the interviewees reported facing some form of online abuse since the pandemic began. Of the 2 interviewees who had not faced online abuse, one managed a health agency's general accounts and the other primarily relied on staff to manage her accounts. In the second phase, we asked the participants more detailed questions about the frequency of online harassment they experienced in the last 6 months. In total, 82% (28/34) of the questionnaire respondents received online threats, harassment, or false claims on multiple occasions in the last 6 months.

About 38% (13/34) of the questionnaire respondents claimed that their nationality or ethnic background was the reason they were targeted with online harassment. Racialized interviewees described how the online abuse they encountered differed from their White colleagues. For instance, a racialized woman stated:

> *There are random people out there that don't like you just because of who you are. Not necessarily because of what you say... I have female colleagues who are White... who say the same thing and don't get the reaction that I get.* [Civil society expert]

These sentiments were repeated by multiple racialized workshop participants.

In total, 18% (6/34) of the questionnaire respondents asserted that their gender identity or appearance was the reason they were targeted. Several women described how the abuse they received tended to emphasize their identity, including references to sexualized acts and derogatory remarks about their professional capabilities based on their gender. One woman explained how she inadvertently put her "whole self" online for scrutiny and, consequently, received many messages laced with "fatphobia and body shaming" (White woman, health journalist). She further explained, "It feels pretty vulnerable to be attacked that way as a young woman... I think it's really been probably the most intense misogyny I've ever faced in my life."

When interviewees recounted the online harassment they experienced, they often described negative emotions (Figure 1). Similarly, 41% (14/34) of the questionnaire respondents

XSL•FO
RenderX

experienced strong negative feelings in response to online harassment (Table 2).

Most health communicators mentioned multiple negative emotions around online abuse. Interviewees commonly mentioned feeling simultaneously frustrated and exhausted when they received a "constant barrage" of online harassment (White woman, public health official). Health communicators were "being fed this stream of negativity and abuse through...your phone all day" (White man, health journalist), and some felt that "even the best possible...person can't deal with an assault of hostility 24-7" (White woman, public health official).

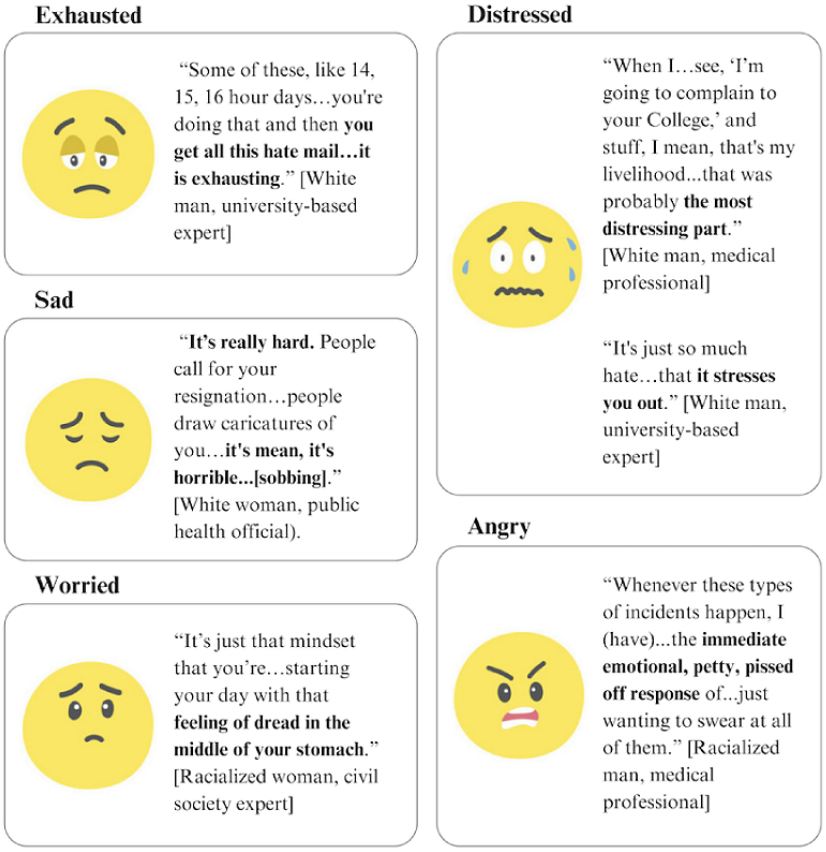
An interviewee reflected on how online harassers were misrepresenting his opinion on certain health topics:

> *That really does sting, and you find it frustrating and you waste...cognitive energy worrying about it.* [White man, university-based expert]

Several health communicators explicitly mentioned the "psychological toll" and "psychological exhaustion" of receiving and reading countless negative, hostile, and threatening e-mails (White man, university-based expert).

Interviewees also frequently expressed feeling sad and scared in the same instance:

> *When I get a hateful message, a...message that threatens violence against me, it makes me feel sad. ...it does scare me. It instills fear in me, and...it makes me feel really sad to know that this person...has taken time out of their day to...send me that message with the hope of hurting me somehow.* [Racialized woman, civil society expert]



While some of the interviewees described symptoms of depression, such as "not wanting to get out of bed...[in the] morning" (Racialized woman, civil society expert), others described symptoms of anxiety, such as difficulty "trying to unplug" (White woman, health journalist). Another interviewee, who received an email with "a message from someone...saying they hope that I get blood clots and like, basically die," explained how these types of messages are anxiety-inducing: "sometimes it keeps you up at night, makes you very worried and concerned" (White woman, health journalist).

Racialized and women health communicators across interviews and workshops discussed how negative comments about their ethnicity, ancestry, and physical appearance impacted their mental health and well-being:

> *When it actually ends up being personal attacks on you as a person, on how you look, on the colour of your skin, where you're originally from...It takes a toll on you.* [Racialized woman, civil society expert]

Interestingly, only 18% (6/34) of the questionnaire respondents claimed to be "struggling with mental health issues" (Table 2), whereas the interviewees repeatedly mentioned how their mental health and well-being had been impacted by health communication and subsequent harassment during the pandemic. This variation in the severity of mental health impacts reported suggests that certain participants implemented strategies to mitigate some of the mental health consequences of online abuse.

Figure 1. Examples of negative emotions expressed by interviewees because of online abuse.

XSL•FO
RenderX

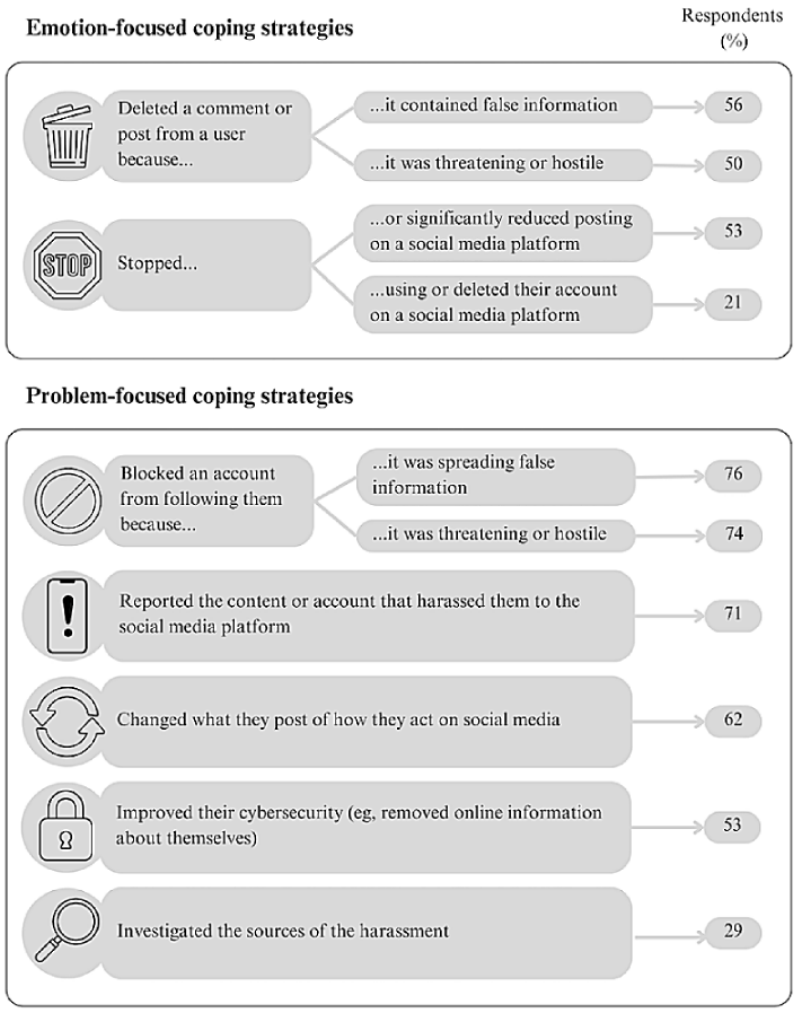


Table 2. Impacts of online harassment on questionnaire respondents.

	Questionnaire respondents (N=34), n (%)
Personal impacts	
Experienced strong negative feelings (eg, fear, horror, anger, guilt, or shame)	14 (41)
Felt scared for the safety of their family and friends	8 (24)
Felt scared for their physical safety	7 (21)
Struggled with mental health issues	6 (18)
Felt jumpy or easily startled	6 (18)
Experienced strong negative beliefs about themselves or other people	6 (18)
Repeated, disturbing dreams of the stressful experience	3 (9)
Professional impacts	
Avoided publicly addressing certain topics	21 (62)
Seriously considered quitting health communication	14 (41)
Requested a change in their professional role	5 (15)
Took a greater number of sick days than usual	2 (6)

Coping Strategies Implemented by Health Communicators

When health communicators experienced online harassment, they used a variety of coping strategies (Figure 2).

Figure 2. Responses to online harassment implemented by questionnaire respondents (N=34).

XSL•FO
RenderX

Emotion-Focused Coping Strategies

Health communicators' most common emotion-focused coping strategies were (1) withdrawing from social media planforms, (2) avoiding social media platforms altogether, and (3) accepting online harassment and abuse as unavoidable.

First, many participants withdrew from online public health communication because of harassment. In total, 53% (18/34) of questionnaire respondents noted that they significantly reduced or stopped posting on a social media platform (Figure 2). Interviewees mentioned that they "used to...be very active on Twitter," (White woman, health journalist) but they "made a conscious choice to distance myself from Twitter as a professional" due to persistent online harassment (White man, health journalist).

Second, 21% (7/34) of questionnaire respondents claimed that they have stopped using or deleted their account on a social media platform (Figure 2). Several health communicators explicitly stated that they avoided social media platforms to safeguard their mental health and well-being. "I felt for my mental well-being, I am avoiding this because it is like a triggering response to see all those notifications coming in again and again and again" (White woman, health journalist). One interviewee said he had "to turn if off" for his "own peace of mind...because there's been an overwhelming amount of negativity," (White man, public health official), and another firmly stated she was "not on Twitter for...[her] mental health" (White woman, public health official).

Several interviewees justified these emotion-focused coping strategies by explaining how sharing public health information was not part of their job descriptions, so they were "not paid to be on Twitter" (Racialized man, medical professional). A racialized civil society expert noted, "It's not as though this is my job...I'm not getting paid for any of this work...[and] on top of that, I get vitriol."

Third, several interviewees seemed to accept the possibility of receiving online harassment. One health communicator conceded that "because of the way that things are now, whatever you share, anything you post...you do open yourself up to some degree of abuse" (White man, health journalist). Another felt disheartened that she was "going to have to be dealing with [online harassment]...for a long time," particularly if she wanted to continue publishing in major outlets and working on "more polarizing" topics (White woman, health journalist).

Health communicators may have relied on emotion-focused coping strategies because they were unaware of problem-focused coping strategies or unable to implement them. One woman asserted that she did not "know how to get back on Twitter without...facing all this same garbage again" (Health journalist). Another admitted that she felt "ill-equipped to...be on the site anymore" (White woman, health journalist).

Problem-Focused Coping Strategies

Scarduzio et al [21] proposed 5 specific "types" of problem-focused coping strategies, including blocking or unfriending, changing online behavior, formal help-seeking, peer intervention, and confronting. Health communicators in our study implemented all 5 of these digital coping strategies to mitigate further online harassment and abuse.

In total, 74% (25/34) of the questionnaire respondents blocked a threatening or hostile account from following them, and 53% (18/34) of respondents improved their cybersecurity (Figure 2). Several interviewees explained the exact steps they took to improve their cybersecurity, such as "taking my face off of my Twitter profile" (White man, health journalist). One interviewee explained how making her "account private" helped her create "a bit of a safer space" online (Racialized woman, civil society expert).

In total, 62% (21/34) of the questionnaire respondents (Figure 2) and many interviewees changed what they posted and how they behaved online. One participant started making an extremely conscious effort to refrain from posting personal information online:

> *It has just made me more cognizant of what I share in general about my life...I never tweet about where I am. I never tweet about the neighbourhood I live in...I didn't want malicious people [to] have that information about me.* [White woman, health journalist]

Other health communicators refrained from sharing public health information because they were "worried about it becoming somehow a lightning rod for hate or harassment or just unwanted negative attention" (White woman, health journalist). For example, some interviewees explained how they no longer shared opinions on "controversial and important topics" (White woman, health journalist), and they "don't advocate outwardly for...[COVID-19] restrictions" (Racialized man, medical professional). Similarly, 62% (21/34) of the questionnaire respondents avoided publicly addressing certain topics (Table 2). As more health communicators resorted to self-censorship, crucial health information became less available to publics.

Other participants described setting boundaries on how they used social media platforms, not as a form of self-censorship but to balance personal well-being with professional efficacy. For instance, when online abuse made his social media engagements particularly stressful, a health official took time away from the platform to develop new strategies for how he would use it:

> *I just reactivated [my account] after a few weeks...Coming back with a few rules in mind, I felt much better.* [Racialized man, public health official]

Some health communicators sought assistance to manage online abuse by reporting the harassment directly via social networking sites' reporting mechanisms. In our study, 71% (24/34) of questionnaire respondents engaged in "formal help-seeking" by reporting the content or account that harassed them to the social media platform (Figure 2). Several interviewees stated that this action did not have a reliable effect, since in some situations the posts or accounts remained on platforms long after the health communicator had reported them. Our interviewees did not discuss how inconsistent action by social media platforms shaped their assessment of the efficacy of this problem-focused coping strategy.

XSL•FO
RenderX

In total, 41% (14/34) of the questionnaire respondents reported acts of online harassment to a supervisor or employer, and 18% (6/34) of respondents sought help from a supervisor or employer (Table 3). Two health journalists found support and directives from their employers to be effective. One journalist explained how the independent news website she writes for "has been really supportive and proactive" by clarifying "the conditions that my work is expected to continue under" (White woman, health journalist). The other journalist described how the mental health supports that her employers have provided were beneficial:

> *Both organizations that I've worked for have really been putting an emphasis on...getting mental health support. I think some big changes that were made structurally to benefits that were being offered in terms of how much mental health support was being covered made a really big difference.* [Racialized woman, health journalist]

These findings suggest that health journalists received more support from their employers than health communicators in other professions.

Other health communicators relied on colleagues and family members to help manage online abuse and stop harassers (ie, "peer intervention"). In response to online harassment, more than half of the questionnaire respondents (18/34, 53%) asked a colleague for help, and 47% (16/34) of respondents asked a friend or a family member for help (Table 3). For instance, members of a public health agency team regularly checked in with each other to provide emotional support, often in the form of humor, and to review potentially abusive messages.

If someone else, such as an employee, colleague, or significant other, could oversee their social media accounts, then health communicators would not have to read negative comments and messages themselves:

> *I was...telling with my campaign team that I actually want to hand...over the keys [to my social media accounts]...because I actually don't want to see it anymore.* [Racialized man, university-based expert]

One public health official described how her "partner joined Twitter partly because he took on the job [of] monitoring my account," but she acknowledged "there's a toll... when you read angry tweets about your partner every day" (White woman, public health official).

Confronting online harassers was not a popular problem-focused coping strategy used by health communicators. Only one interviewee explained that she wanted to engage with perpetrators of online harassment "because criticism and conflict eats at" her, and it was "empowering" to try to connect with those who were unnecessarily hostile (White woman, university-based expert). She noted that, "I've engaged twice, by phone and it actually worked."

Table 3. Sources of reporting and support for questionnaire respondents who experienced online harassment.

	Questionnaire respondents (N=34), n (%)
To whom did you report the acts of online harassment?	
Social media platforms	22 (65)
Supervisor or employer	14 (41)
Professional association or governing body	6 (18)
Police	4 (12)
Government or political representative	1 (3)
Unions	1 (3)
I did not report any acts of harassment	5 (15)
From whom did you seek support?	
Asked a colleague for help	18 (53)

Continuation of Online Health Communication

Health communicators' experiences of online abuse prompted them to reflect on their long-term use of social media to engage publics. We identified 2 broad groups: those who felt the negative impacts of online harassment on their mental health and well-being outweighed the potential benefits of public health advocacy and those who expressed a desire to continue sharing relevant public health information despite online harassment. Health communicators discussed the internal conflict between reducing their engagement to protect their mental health and continuing their advocacy. One interviewee, after being targeted on Twitter for discussing abuse she and other journalists faced, stopped engaging with those issues online:

> *That was honestly really frustrating because I felt that at a time that I really needed to be vocal about these things, I couldn't without compromising my safety and my mental well-being. It kind of felt like there was no good option: either stay silent about what had been done or speak out and perhaps welcome more harm.* [White woman, health journalist]

Those in the first group generally reduced their online engagement to prioritize their mental health and well-being:

> *My mental health and well-being are more important than the hope that maybe...these people will learn...because they're not going to learn.* [Racialized man, medical professional]

Similarly, a participant who used online platforms to remain engaged with health issues reported that he began to believe those benefits are being outweighed by "the risks to my mental health and well-being...and the threats to my productivity" (Racialized man, university-based expert).

In total, 41% (14/34) of questionnaire respondents seriously considered quitting health communication (Table 2). An interviewee explained how burnout prompted him to take a step back from his profession during the pandemic:

> *I was just kind of tired, I guess...I certainly felt burnt out from reporting on the pandemic...There are still COVID stories that are important to tell and there's important journalism to be done, but I felt as if I didn't want it to be done by me anymore.* [White man, health journalist]

Conversely, interviewees in the second group explained why and how they would continue to engage in online health communication despite the challenges:

> *I do feel upset for a little bit (after experiencing online abuse), but it has never gotten to a point where I would think to myself, "I'm not going to do this ever again." I know of people who have given up, who've taken time off or just completely stopped engaging, but...at least for now, I haven't reached that point.* [Racialized woman, civil society expert]

Several participants emphasized that they continued to advocate online because they believed in the public benefit of sharing health information:

> *I'm just trying to tell (people) the facts. And to be targeted for being the messenger of those facts is not very fun. There have been times because of the backlash that I've thought, well, maybe I won't tweet as much. And I definitely had that thought a few times during the course of the pandemic. I really had to weigh...(is) me getting a few messages that are annoying more important than me trying to get information out to people? And for me, getting information out is always more important.* [Racialized woman, health journalist]

Although most health communicators implemented a variety of problem-focused and emotion-focused coping strategies (Figure 2), only some demonstrated a strong willingness to continue their online engagement, whereas others contemplated quitting public health communication. In the face of persistent online abuse, *continuing* to post online could be understood as an act of "professional resilience." Health communicators who faced challenges overcoming the mental health and well-being impacts of online abuse were more likely to reduce or abandon their online advocacy efforts.

Discussion

Impacts of Online Abuse

Throughout the COVID-19 pandemic, many health care providers, researchers, public health officials, and health journalists put extraordinary effort into engaging publics online, which often exposed them to unwanted harassment and abuse [10]. Although online harassment is often dismissed because it occurs in virtual environments, the consequences of such harassment can be very real, including psychological stress and burnout [13]. Among our questionnaire respondents, 82% (28/34) faced online harassment or abuse. Therefore, most participants reported negative emotions, including feeling fatigued, sad, distressed, and angry. Some participants shared symptoms of anxiety and depression, and some explicitly reported that they had been struggling with mental health issues. This emotional distress caused by online harassment has exacerbated the widespread burnout experienced by medical professionals during the COVID-19 pandemic [26].

Coping Strategies for Online Abuse

Participants in this study mentioned a variety of strategies to cope with the mental health impacts of online harassment. Drawing on the framework proposed by Lazarus and Folkman [17], we categorized these as emotion-focused and problem-focused coping strategies [21,27,28].

Participants' most common emotion-focused coping strategies were enduring or ignoring online harassment and disengaging or withdrawing from social media platforms. Several interviewees seemed to accept online harassment as something that came with the territory, rather than something that could be mitigated with problem-focused coping strategies. This sentiment aligns with other research findings that many scientists who publicly commented on the COVID-19 pandemic said they learned to cope with online harassment by "accepting it as an unpleasant but expected side effect of getting information to

XSL•FO
RenderX

the public" [10]. Furthermore, research suggests that many health communicators have purposefully ignored and not responded to social media trolls [10,11,29], since "engagement is their oxygen" [5]. Other emotion-focused coping strategies for online abuse reported by health communicators in our study and the literature include deleting negative comments, reducing engagement on social media platforms, avoiding certain social media platforms, and deleting social media accounts altogether [5,10,29]. Although self-blame has been identified as an emotion-focused coping strategy in other studies [16], no health communicator in our study described blaming themself for the online harassment they received.

Health communicators also used many problem-focused coping strategies to respond to online abuse. As opposed to reactive emotion-focused strategies, such as deleting negative comments, problem-focused strategies tend to be more proactive, such as blocking or reporting hostile users. For example, by preventing such users from sending messages directly to the communicator or seeking to have social media platforms enforce their terms of service against online harassment, health communicators have tried to limit the number of negative or threatening messages they will receive *in the future*. One academic told other researchers that she even blocked her abuser's followers to make it harder for them to target her [10]. Health communicators in our study and in the literature have taken several proactive steps to avoid receiving online abuse, including refining cybersecurity settings by making accounts private [11,29] and removing contact information from public websites [5].

Furthermore, rather than avoiding posting on social media platforms *entirely*, many health advocates became "more careful about how...[they] use" social media [10], making conscious efforts to strategically avoid posting about *specific* topics online. In fact, 63.5% (228/359) of the physicians, biomedical scientists, and trainees in the United States who reported experiencing any online harassment during the pandemic claimed that they have *changed* how they use social media [12]. Many health communicators, in the literature and our study, have begun compartmentalizing professional and personal identities online, avoiding "making comments that might be perceived as political" or controversial [10], or refusing to correct misinformation online [29].

When we examined help-seeking behaviors among our participants, we found a distinction between *reporting* online harassment and *seeking support* for such harassment. While almost three-quarters of questionnaire respondents (24/34, 71%) formally reported online harassment directly to social media platforms, when the same respondents recorded who they asked for help, colleagues (18/34, 53%) and friends and family members (16/34, 47%) were the most common sources of support. Several interviewees explained how their employees or loved ones helped them manage online abuse, limiting the number of negative comments and direct messages they read about themselves. Similarly, Hodson et al [30] reported that women scholars who experienced online harassment were most likely to try to deal with the problem by enlisting the help of spouses, close family members, or friends to help manage their online presence. Social media platforms allow users to report and block hostile users [31], but taking these actions may not be as effective in improving health communicators' mental health and well-being as receiving assistance and emotional support from friends and family members [30]. However, our study focused on health communicators' perspectives on the efficiency of various coping strategies, rather than examining social media platform activity. Thus, we cannot directly assess whether health communicators' reports of hostile users were acted on by platforms or whether these platform responses shaped health communicators' assessments on the efficacy of this strategy.

Some scholars have discussed how emotion- and problem-focused coping strategies can be difficult to discern, and we also found some overlap between the 2 categories. For example, Scarduzio et al [21] described asking friends and family members "for support and advice" as an active emotion-focused coping strategy yet asking friends and family members "to help stop the harasser" as a problem-focused coping strategy. Thus, we acknowledge that some coping strategies may fall into a "gray zone" between emotion-focused and problem-focused.

Although confrontation was an unpopular problem-focused coping strategy among health communicators in our study, some participants expressed a desire to have productive dialogues with their harassers. One physician said she occasionally responded to comments or messages but not when she was upset or angry [10]. However, confronting perpetrators may pose a risk of further abuse and negative mental health consequences [32], which could be one reason most health communicators in our study and the literature relied on other coping strategies.

We found some problem-focused coping strategies were individual in nature, while other strategies involved support through personal and professional relationships or official organizational policies. Individual strategies, like blocking hostile accounts, can lessen exposure to online abuse and, consequently, lessen the impacts of such abuse on mental health and well-being. Another strategy to lessen exposure is sharing the burden of monitoring and responding to hostile content with friends, loved ones, or colleagues. Beyond reducing exposure to online abuse, social and organizational support can strengthen a health communicator's ability to emotionally process abuse and rebuild mental health. For example, 2 journalists in our study, who demonstrated a willingness to continue their professional advocacy, highlighted the importance of access to expanded employee benefits, which enabled them to take time off work and receive counseling after experiencing online abuse. In the workshops, several public health officials described how their teams routinely discussed the hostility they received to address any sense of isolation or personal responsibility for these reactions and to share coping strategies. Conversely, health communicators in our study who worked as freelancers or in individual medical practices noted that a sense of isolation and lack of workplace support had exacerbated the mental health consequences of online abuse.

Professional Resilience Among Health Communicators

There are several opinions about the effectiveness of emotion- and problem-focused coping strategies, but many scholars argue

XSL•FO
RenderX

that problem-focused strategies are more beneficial in the long-term [17,33]. Our findings suggest that health communicators who used problem-focused coping strategies were more likely to continue their advocacy than health communicators who used emotion-focused coping strategies. In the face of persistent online harassment and abuse, Veletsianos et al [16] reported that women scholars who continued working and teaching "required determination and resilience." Thus, simply continuing their professional obligations became an act of resistance [16]. Similarly, we put forth that health communicators who remained "active" online demonstrated significant professional resilience, compared to those who censored or otherwise minimized their online presence. Several communicators in our study noted their commitment to sharing important health information broadly with publics was one reason for this resilience. Some of the clearest expressions of professional resilience were shared by racialized health communicators in our study, which warrants further investigation.

Importantly, we do not define professional resilience as an individual quality or character trait. An individual's capacity to continue using online spaces to inform and advocate publics is significantly shaped by the forms and intensity of online abuse they face as well as the interpersonal and institutional support they receive. Moreover, the extraordinarily high levels of online engagement by health communicators during the COVID-19 pandemic required many health experts to take on burdens that went beyond their job descriptions or were otherwise unsustainable.

Online and in-person abuse has contributed to burnout and high turnover among health communicators, particularly medical professionals and health journalists [11]. Many participants in our study contemplated reducing or ceasing their online health communication activities. This decision could have negative professional consequences, such as a reduction in opportunities to network and collaborate with other scholars [9]. These consequences were especially pronounced for women and racialized individuals, who have historically been excluded from academia. Women who have reported considerable online harassment, especially sexual harassment, have frequently responded by reducing and censoring their online participation as well as deleting their accounts on social media platforms [9,16,34], further limiting their opportunities for professional development.

There are also broader social consequences if health communicators reduce their engagement online. Notably, misinformation and disinformation may be left unchecked by those most qualified to counter it [12]. Experts who were attacked online said they were less likely to participate in future media interviews, highlighting the effectiveness of these attacks [7]. Similarly, scientists who reported the highest frequency of trolling in the *Nature* survey were most likely to report that their experiences have greatly affected their willingness to speak to the media in the future [10]. At a time when "we've never needed them so badly" [10], many health communicators are avoiding certain topics on social media or withdrawing from these platforms entirely. Furthermore, given the alarming amount of abuse reported by senior public health officials, it seems likely that the hostile online environment could dissuade up-and-coming health communicators from fully engaging in important discussions [6]. Consequently, we may see a reduction in the diversity of thoughts and opinions shared within academia and public discourse, especially if women and racialized academics are disproportionately pushed out of online spaces [16].

Policy Recommendations

Health communicators in our study implemented various emotion- and problem-focused coping strategies, many of which they implemented as individuals. Future studies should investigate the effectiveness of these digital coping strategies for health communicators' mental health, well-being, professional efficacy, and professional resilience, especially those who belong to gender and racial minorities.

Our findings also highlight the limitations of individual coping strategies, necessitating the development of organizational policies to support those who receive online abuse and sanction those who perpetrate it. While health communicators have taken many steps to mitigate the frequency and severity of harassment they experience on social media platforms, advocates argue that individuals should not have to "cope on their own" [10].

Advocates have asserted that there is much that institutions can do to assist scientists who are receiving online abuse [10]. Studies have suggested several actions for institutions that employ health communicators: creating formal policies to guide health communicators' digital interactions [19], hosting trainings for health communicators on how to engage with the media and what to expect from online trolls [5,10], and enlisting organizations' information technology departments to block consistent abusive emailers and report incidents to social media platforms and police [10]. These organizational efforts should address the potential for different forms of abuse based on individuals' gender identity, race or ethnicity, ancestry, and other sociodemographic characteristics. In our study, the strongest examples of organizational policies were provided by health journalists and communicators at public health agencies. These examples include (1) clear recognition from superiors that online abuse is a serious problem that requires action and (2) institutional programs providing psychological therapy, cybersecurity assistance, and peer support. This finding warrants an exploration of organizational polices across industries to ascertain and promote best practices. Programs are also needed to support health communicators who are not full-time employees of large organizations, such as family doctors, free-lance journalists, and others.

While individual actions may have immediate short-term outcomes, institutional policies and practices could have sustained long-term outcomes for health communicators' mental health and well-being by preventing online harassment or, at least, mitigating it. Organizational policies would support professional resilience, ensuring that important health information is "not silenced" by online abuse and can still reach publics [10].

Limitations

There are several limitations to this study. Our purposive sampling of health communicators who were highly engaged in online health communication provided findings from an important population but not necessarily a representative one. Our study was conducted in English, which might have precluded insights from Canada's significant French-speaking population. Moreover, because of the small sample size of our study, we could not quantitatively compare exposure to online harassment by gender identity, ethnicity, or professional role. A more comprehensive sample of health communicators across institution types, professional roles, and sociodemographic characteristics could identify broader patterns and gaps in our findings as well as greater insights into the experiences and coping strategies of members from marginalized populations. Finally, this study focuses on health communicators in Canada and their experiences during the first few years of the COVID-19 pandemic, when uncertainty and fear were heightened. Further comparative studies across countries are needed to measure the long-term impacts of online abuse and coping strategies on health communicators in different political and health care contexts.

Conclusions

This study elucidates the significant impacts of online abuse on health communicators during the COVID-19 pandemic, highlighting both mental health and professional consequences. Despite the variety of individual coping strategies used by health communicators, there remains a pressing need for organizational efforts that offer comprehensive protection against online abuse and support for those who receive it. Institutions must acknowledge that the burden of coping with online abuse should not fall solely on individuals and that they should be supported by formal organizational policies and practices that safeguard the mental health, well-being, and professional efficacy of health communicators. These efforts will support individuals at the forefront of public health communication to share critical information.

Acknowledgments

The authors are grateful for the interviewees and workshop participants who shared their insights and experiences, some of which were quite difficult. They deeply appreciate research assistance from Hannah Hett, Sabah Haque, and Oliver Zhang, as well as feedback from Jaigris Hodson, Elizabeth Dubois, and George Veletsianos. The authors would like to thank ScienceUpFirst, which helped them engage a broader community of health communicators. This study has been made possible by funding from the New Frontiers in Research Fund (NFRFR-2021-00289) by the government of Canada and from the Bridge Research Consortium, a part of Canada's Immuno-Engineering and Biomanufacturing Hub.

Authors' Contributions

CT, SH, and HT conceptualized the study. CT collected interview and survey data. CT and a research assistant coded the qualitative data. LW analyzed the quantitative and qualitative data with support from SH and CT. LW drafted the manuscript. CT, SH, and HT reviewed and edited the manuscript. All authors read and approved the final manuscript.

Abstract

Background: Social media is widely used by the general public as a source of health information because of its convenience. However, the increasing prevalence of health misinformation on social media is becoming a serious concern, and it remains unclear how the general public identifies and responds to it.

Objective: This study aims to explore the approaches used by the general public for identifying and responding to health misinformation on social media.

Methods: Semistructured interviews were conducted with 22 respondents from the Malaysian general public. The theory of motivated information management was used as a guiding framework for conducting the interviews. Audio-taped interviews were transcribed verbatim and imported into ATLAS.ti software for analysis. Themes were identified from the qualitative data using a thematic analysis method.

Results: The 3 main themes identified were emotional responses and impacts of health misinformation, approaches used to identify health misinformation, and responses to health misinformation. The spread of health misinformation through social media platforms has caused uncertainty and triggered a range of emotional responses, including anxiety and feelings of vulnerability, among respondents who encountered it. The approaches to identifying health misinformation on social media included examining message characteristics and sources. Messages were deemed to be misinformation if they contradicted credible sources or exhibited illogical and exaggerated content. Respondents described multiple response approaches to health misinformation based on the situation. Verification was chosen if the information was deemed important, while misinformation was often ignored to avoid conflict. Respondents were compelled to take action if misinformation affected their family members, had been corrected by others, or if they were knowledgeable about the topic. Taking action involved correcting the misinformation and reporting the misinformation to relevant social media, enforcement authorities, and government bodies.

Conclusions: This study highlights the factors and motivations influencing the general public's identification and response to health misinformation on social media. Addressing the challenges of health misinformation identified in this study requires collaborative efforts from all stakeholders to reduce the spread of health misinformation and reduce the general public's belief in it.

Introduction

Background

Social media has increasingly been used by the general public for health-related purposes, primarily for receiving social support and searching for and sharing health information [1]. Social media platforms offer unlimited access to prompt and easily accessible health information, making them a preferred channel for seeking health information [2]. The most commonly used social media platforms for this purpose include WhatsApp (WhatsApp LLC), YouTube (Google LLC), Facebook (Meta Platforms, Inc), and X (formerly known as Twitter; X Corp) [2,3]. Studies have shown that between 76% and 85% of respondents, including the general public and patients aged ≥18 years from Saudi Arabia and the United States, search for health information on social media [2,4].

Although social media may offer some advantages in the dissemination of health information, there is growing concern about the prevalence of health misinformation on these platforms. Health misinformation is defined as a health-related claim that is false or misleading because of a lack of supporting scientific evidence at a given time [5]. Studies have shown that the quality of health information on social media is generally poor, based on criteria such as content accuracy, information design, credibility, disclosure of user information, and interactivity [6]. A systematic review found that the 3 most common topics with health misinformation on social media were vaccines (32%), drugs and smoking issues (22%), and noncommunicable diseases (19%) [5].

Health misinformation can be harmful as it can cause unnecessary fear and lead the general public to make inappropriate decisions about their health, which can worsen physical health and even lead to increased morbidity and mortality [7-10]. One example is the widespread antivaccine content on social media that has contributed to decreases in vaccine acceptance and vaccination rates as well as an increase in preventable disease outbreaks [7]. Physicians have also expressed concerns about the dangers of health misinformation, describing regular encounters with patients who were hesitant to take potentially lifesaving medications or adhere to prescribed treatments owing to misinformation on the internet and social media [8]. Moreover, the narratives found in health misinformation often instill fear, anxiety, and mistrust in health institutions [9]. For example, health misinformation circulating on social media during the Ebola virus outbreak created hostility toward health care workers and contributed to challenges in efforts to control the epidemic [11]. In addition, misinformation may cause the general public to have reduced adherence to government public health policies, rendering these efforts ineffective [12-16].

Previous research has demonstrated that various factors can influence the perceived credibility of health misinformation on social media. These factors may collectively contribute to the rapid spread of misinformation, particularly during health crises such as the COVID-19 pandemic. One identified factor is the inclusion of claims of background evidence, such as an attached link or source, in misinformation messages, which can make messages appear more credible to the general public [17]. Social endorsements, such as a higher number of likes and shares, also enhance believability [18-20]. The perceived credibility of the message's source is also important, with individuals tending to trust messages from respected authorities, close contacts, influencers, or celebrities, leading to further misinformation spread [20,21]. Health care professionals and organizations are often perceived as reliable sources of information; however, they are also exposed to misinformation on social media [17,22]. A qualitative study among physicians and nurses in the United States identified several cues for spotting health misinformation, including messages with exaggerated claims, grammar errors, unreliable links, and conspiracy content [22].

The general public's response to health misinformation on social media, if they are able to identify it, has been shown to be influenced by their beliefs, cultural factors, and social media use. Beliefs in conspiracy theories, such as government secrets, and cultural beliefs, such as trust in traditional treatments over scientific evidence, contribute to the spread and acceptance of misinformation, as observed during the COVID-19 pandemic [23,24]. General public reactions to misinformation on social media also vary; some people choose to disregard the information [25], while others challenge and report it [26]. Fact-checking has been shown to reduce the spread of misinformation, but heavy reliance on social media as information sources reduces the critical verification process, leading to the further spread of health misinformation [27].

Due to the urgency of this issue, various measures have been proposed and adopted by organizations, governments, health care workers, and researchers to combat health misinformation on social media. These measures include regulating social media content, skillfully communicating public health messages, promoting verification and correcting health misinformation, warning about the sources of information, promoting evidence-based medicine, educating the general public about health information, conducting fact-checking efforts, improving critical thinking skills, and enhancing media and health literacy [10,28-31]. For example, the World Health Organization (WHO), recognizing the mounting concerns about health misinformation on social media, has adopted numerous measures to combat it, such as providing an avenue for reporting health misinformation, creating a MythBusters web page to debunk misinformation with facts and figures, and working toward amendments in social media policies [32,33]. While this is recognized as a pressing issue requiring a multidisciplinary effort, effectively addressing it requires a deeper understanding of how the general public identifies and responds to health misinformation on social media platforms. This understanding will enable the identification of areas requiring concerted efforts from all stakeholders to mitigate the spread of health misinformation and reduce the general public's belief in it.

While previous studies on health misinformation have primarily focused on regions such as Europe, the Middle East, Africa, and parts of Asia, Southeast Asia remains underrepresented in this field of research [34,35]. Nevertheless, there has been notable rise in health misinformation on social media within the South East Asian region [35]. Given that culture plays a significant role in how health misinformation is perceived and

XSL•FO
RenderX

managed [36-38], it is important to explore this issue within a Southeast Asian context. As a multicultural and multilingual country, Malaysia offers a unique setting for such studies [39]. The diverse cultural backgrounds and traditions within the Malaysian population can influence health information–seeking behaviors [40] and provide additional insights into health misinformation on social media. However, no studies have specifically examined how the Malaysian general public identifies and responds to health misinformation on social media. Therefore, this study aims to explore the approaches used by the Malaysian general public to recognize health misinformation on social media and their responses to it.

Theory of Motivated Information Management

The theory of motivated information management (TMIM) serves as a guiding framework in this study. The TMIM explains how uncertainty influences information management behaviors [41] and has been widely applied to explore the barriers and motivations behind health information seeking [42-45]. While its application to health misinformation is relatively limited, it may offer valuable insights into how individuals engage with, process, and respond to health misinformation encountered on social media. It can also help explain how feelings of uncertainty drive health information–seeking behaviors in the context of health misinformation [46].

This theory is structured into 3 phases: interpretation, evaluation, and decision. In the context of health misinformation on social media, the interpretation phase occurs when individuals recognize discrepancies or uncertainties in health information or misinformation they encounter. This recognition may trigger emotional responses, such as anxiety, which can influence their approach to managing the information. Next is the evaluation phase, where individuals assess their ability to reduce uncertainty through health-related information seeking and consider the potential outcomes—both positive and negative—of obtaining new information. The likelihood of seeking information is influenced by individuals' perceived ability to cope with the expected outcomes (coping efficacy), their ability to manage the communication process involved in seeking information (communication efficacy), and the perceived reliability of the information source (target efficacy). Finally, the decision phase determines the individuals' course of action based on the evaluations from the previous phase, such as whether to search for additional health information or disregard the health misinformation encountered [41].

Methods

Study Design and Participants

This qualitative study involved individual semistructured interviews with members of the general public in Malaysia. This study design was selected to allow a deeper exploration of the factors influencing the management of health misinformation in this population, providing richer insights into the issue.

The respondents were initially recruited through advertisements posted on social media platforms, including Facebook, Instagram (Meta Platforms, Inc), WhatsApp, and X. Those who were interested in participating completed a Google Form providing their sociodemographic information and details about their social media activity. Potential respondents who met the inclusion criteria, which included being Malaysian, aged >18 years, and active social media users on the specified platforms, were then contacted. Individuals who were unable to participate in web-based interviews or could not speak English or Malay were excluded. For this study, active social media users were defined as individuals who engaged with content by liking, commenting, and sharing information on Facebook, Instagram, X, and WhatsApp. These social media platforms were selected because they are the most commonly used for seeking and sharing health information in Malaysia [47].

The respondents were then purposively selected by the researchers to ensure a diversity of sociodemographic characteristics, such as age, education, occupation, income, gender, state of residence, and religion. This was done to gather a broad range of views and perspectives on the issue of health misinformation in Malaysian social media and the responses toward it.

Ethical Considerations

This study was approved by the Human Research Ethics Committee of Universiti Kebangsaan Malaysia (JEP-2022-037). Before conducting the interviews, the purpose of the interviews was explained to the participants, and their written informed consent was obtained. To ensure privacy and confidentiality, all transcripts were anonymized through pseudonymization. Each participant was assigned a unique identifier, and all potentially identifying information was removed during transcription. Only the research team had access to the anonymized data, which was stored on a secure, password-protected server. Following the interviews, RM 50 (US $11) was credited into the e-wallets of the respondents as compensation for their participation in this study.

Data Collection

An interview guide was developed based on domains identified through literature review and guided by the TMIM framework, as outlined earlier [41]. Table 1 presents examples of interview questions aligned with the 3 key phases of the TMIM. In the interpretation phase, questions were designed to explore the types of health misinformation encountered on social media; the uncertainty recognized in the information; and the emotional responses triggered, such as anxiety. In the evaluation phase, interview questions focused on understanding how individuals identify health misinformation, their perceptions of social media as a source of health information, and their confidence in seeking accurate information and assessing its reliability. Finally, questions in the decision phase explored how individuals respond to health misinformation based on their evaluations, including disregarding the misinformation or using strategies for verifying health information. The interview guide was piloted with 2 respondents and amended to improve clarity and length. The pilot interviews were not included in the final analysis.

XSL•FO
RenderX

Table 1. Examples of questions used during the interview.

TMIM[a] phases [41]	Description	Examples of questions
Interpretation	Individuals recognize discrepancies or uncertainties in health misinformation, which may trigger emotional responses.	• Have you ever encountered information that conflicts with your beliefs? • If so, what was the information? • How did you feel upon encountering this (mis)information? • What was your initial reaction? • What do you think are the risks of health misinformation?
Evaluation	Individuals assess their ability to reduce uncertainty through health information seeking and evaluate potential outcomes.	• What would you do when you are unsure about health information encountered on social media, and why? • How did you determine whether it was health misinformation? • How do you assess whether an information source on social media is credible or not? How confident are you in your evaluation?
Decision	Individuals decide on the course of action based on their evaluations.	• What would you do if you discovered that health information encountered on social media is misinformation? • How would you respond, and why? • How would responding this way make you feel? • Would you seek further information, and why?

[a]TMIM: theory of motivated information management.

The individual interviews were conducted online via Zoom (Zoom Video Communications) between June 2022 and February 2023. The interviews were conducted in English and Malay. Each interview session lasted between 35 and 62 minutes, with an average duration of 40 minutes. All interviews conducted were audio recorded with the respondents' consent, and field notes were taken during the interview sessions. The audio recordings of the interviews were transcribed verbatim. Interviews conducted in Malay were first transcribed in Malay and then translated into English, with the translations reviewed by bilingual research team members. The transcripts were assigned a code, and potentially identifying information was removed. The transcripts were anonymized through a pseudonymization procedure. Data collection was conducted until data saturation was reached, which was determined by the repetition of themes and the absence of new insights. This was assessed collectively by the research team, who continuously compared data from interviews to identify recurring themes among respondents. Data collection continued until all emerging themes were fully explored and stopped when no new codes or themes emerged from the last 3 interviewees [48].

Data Analysis

The transcripts were imported into ATLAS.ti (ATLAS.ti Scientific Software Development GmbH) to facilitate the coding process and identify themes from the qualitative data. The reflexive thematic analysis method by Braun and Clarke [49] was used, following 6 phases, which included familiarization with the data, identifying initial codes, searching for themes, reviewing themes, classifying themes, and generating reports. Initially, inductive coding was conducted independently by SS and WWC to derive preliminary codes from the data. These initial codes were subsequently reviewed, compared, and discussed in depth during multiple iterative meetings between the researchers to ensure rigor and consistency. Following this, abductive coding, guided by the TMIM framework, was incorporated to interpret and refine the codes and themes. Specifically, TMIM was applied to interpret and refine the categorization of themes by incorporating insights into how individuals manage uncertainty and seek or avoid information. This theoretical lens helped clarify the motivations behind participants' behaviors, ensuring that the themes captured both empirical patterns and underlying motivational processes [50]. Final codes were determined through discussion-based consensus. Themes and subthemes were identified based on significant patterns observed in the data and were continuously revised and refined using the constant comparison approach [51]. Field notes were used to aid early analysis, and reflexivity was maintained by the researchers throughout the interviews and analysis phases via memos collected during and after the interviews [52]. All themes and subthemes were finalized through discussions among research team members until a consensus was achieved.

Results

Overview

A total of 22 respondents participated in this study. Respondents represented a diverse range of demographics, including age groups (ranging from 19 to 54 years), levels of education (ranging from secondary school to postgraduate degrees), incomes (ranging from <RM 1000 to >RM 6000), and professional backgrounds (including unemployed, self-employed, private sector, and government) and came from different states across Malaysia. The detailed characteristics of the respondents are included in Table 2.

XSL•FO
RenderX

Table 2. Respondents' demographics.

Respondent number	Age	Sex	Education	Employment sector	Family income[a]
1	27	Female	First degree	Private sector	RM 5000-RM 6000
2	32	Male	First degree	Private sector	>RM 6000
3	54	Female	First degree	Government sector	>RM 6000
4	36	Female	Postgraduate	Government sector	>RM 6000
5	19	Female	Diploma (postsecondary level)	None	>RM 6000
6	25	Male	First degree	Private sector	RM 3000-RM 4000
7	31	Female	First degree	Private sector	>RM 6000
8	23	Female	First degree	Private sector	>RM 6000
9	30	Male	Postgraduate	None	<RM 1000
10	49	Female	Diploma	Government sector	RM 4000-RM 5000
11	19	Male	Diploma	None	RM 3000-RM 4000
12	40	Male	First degree	Self-employed	RM 5000-RM 6000
13	29	Female	First degree	Government sector	>RM 6000
14	22	Female	Secondary School	Private sector	RM 1000-RM 2000
15	33	Female	Postgraduate	Private sector	>RM 6000
16	32	Male	Postgraduate	Government sector	RM 5000-RM 6000
17	37	Female	Diploma	Private sector	RM 2000-RM 3000
18	31	Female	First degree	Private sector	<RM 1000
19	23	Male	Secondary School	Private sector	RM 4000-RM 5000
20	34	Male	First degree	Private sector	>RM 6000
21	22	Male	First degree	None	RM 2000-RM 3000
22	29	Male	Postgraduate	None	<RM 1000

[a]RM 50=US $11.

In total, 3 main themes were identified and will be discussed in detail in subsequent paragraphs with representative quotes: emotional responses and impacts of health misinformation, approaches used to identify health misinformation, and responses to health misinformation.

Emotional Responses and Impacts of Encountering Health Misinformation on Social Media

Respondents generally regarded health misinformation as a serious issue with important and potentially harmful consequences. Many reported encountering such misinformation across various social media platforms, including WhatsApp, X, Facebook, and TikTok (ByteDance). The topics described included misleading claims about COVID-19 (eg, consumption of clove water, coconut water, or black pepper water as cures for COVID-19), conspiracy theories regarding health treatments (eg, pharmaceutical companies concealing cancer cures), vaccinations (eg, vaccines causing autism or COVID-19 vaccines containing tracking devices), and pseudoscientific claims related to traditional supplements (eg, turmeric curing all ailments).

Respondents described a variety of emotions when they encountered health misinformation on social media. They felt uncertainty because of the conflicting information being spread, leading to worry as they were unsure which was correct. In addition, when they came across health misinformation on social media, they experienced self-doubt, questioning their own knowledge as the health misinformation conflicted with their own understanding of the health issue at hand:

> *This is worrying as one person says something and another person says something else. So, we are not sure if it is right or wrong.* [Respondent 11]
>
> *It would get me thinking that whatever I studied, is it wrong?* [Respondent 7]

They explained that they felt scared as they saw even health care professionals spread health misinformation on social media, especially during the peak of the COVID-19 pandemic when everyone was uncertain about what was happening. This further led to feelings of vulnerability as they were not from a health care background, and with health care professionals themselves believing health misinformation, this put them in a more vulnerable position:

> *I saw videos with healthcare workers saying that vaccination could make our immune system worse. This is scary for me as if they can be uncertain about it, what about those who are not from a healthcare background?* [Respondent 7]

XSL•FO
RenderX

Besides that, some respondents described feeling angry as they found the health misinformation spreading on social media to be ridiculous. They further explained that this health misinformation was selling hope to those who were sick, which they felt was very irresponsible. Furthermore, another respondent noted that during the peak of the COVID-19 pandemic, when vaccination was promoted by authorities as a solution, the spread of antivaxxers on social media led to anxiety, as they felt they were exposed to the virus when they came across them in a public area:

> *Who says coconut water can kill Covid-19? They make me so angry.* [Respondent 1]
>
> *How can this kind of food recover the function of the kidneys? It's irresponsible to be spreading this information. They are selling hope. Those who are sick are willing to do anything or spend money to get their health back.* [Respondent 12]
>
> *It gives us anxiety when faced with anti-vaxxers, especially at the peak of the pandemic.* [Respondent 2]

Some respondents described feeling disappointed as they were lied to with promised recovery through miraculous treatment options that failed:

> *You just feel you're being lied to, and then you get your hopes down.* [Respondent 22]

However, a few respondents indicated that misinformation was rare and not serious or significant. This was because they rarely encountered misinformation and had only mild or no effects:

> *It is rare that there is misinformation at all.* [Respondent 18]

Approaches Used to Identify Health Misinformation

Respondents indicated the approaches they used to identify health misinformation, which can be divided into 2 subthemes: message characteristics and the source of the message on social media.

Message Characteristics

Respondents examined the characteristics of social media messages to decide whether they were health misinformation. This comprised the message content and layout.

Respondents decided that it could be misinformation when claims were illogical and exaggerated or when the message claimed that the product is a magical cure for every ailment and was too good to be true. In addition, it was potentially misinformation if the tips or treatment suggested were too simple compared with the severity of the illness at hand, whereby the information provided was deemed to be clearly false:

> *If it is either too good to be true or sounds ridiculous.* [Respondent 2]
>
> *It is not logical, how can this type of herb cure everything?* [Respondent 12]

Some respondents also expressed doubt about the products being promoted, as they lacked proper dosage guidelines in comparison to medications provided by health care professionals. One respondent highlighted that messages that appear visually unattractive should be investigated further, as official information would be created with much thought and graphics to ensure appropriate dissemination of information to the public. In addition, messages circulated on WhatsApp with the caption *forwarded many times* should be approached with caution:

> *As most of the time, it is simply forwarded many times. When we see this tag on WhatsApp, it has a high chance of being something that is circulated for the sake of circulating, while nobody actually knows whether it is correct.* [Respondent 22]

Source of Message

Overview

Respondents highlighted that health misinformation was commonly encountered on blogs, Facebook, X, and WhatsApp groups. They identified several key factors related to the source of a message when determining whether health information was misinformation. These factors can be grouped into 3 main areas: verifying misinformation through source credibility, which focuses on the objective validation of the source based on institutional backing or official endorsements; social trust and misinformation on social media, which emphasizes the role of perceived trustworthiness and social influence of the message source; and sociodemographic influences on source credibility, which considers how factors such as education level, geographic location, and age shape the perceived credibility of the source.

Verifying Misinformation Through Source Credibility

The perceived credibility of the information source was a major factor in identifying health misinformation. Respondents consistently mentioned that health misinformation was often associated with sources that lacked verification or evidence-based backing. Government bodies, such as the Malaysian Ministry of Health, and verified organizations (eg, nongovernmental organizations with blue-ticked social media accounts) were seen as more trustworthy. Messages that contradicted or lacked support from these credible sources were more likely to be considered misinformation. For instance, a lack of official approval or research backing from the Ministry of Health, or promotion of unregistered products, were key indicators that the information could be false. In addition, information not reported by traditional media sources was also deemed as possible misinformation:

> *Suppose they have at least a blue tick source, I will be more confident as some government pages and NGOs have a blue tick. You know they are verified and that gives a bit more trust factor. But if it is only some small shop that sells health ointments or whatever, like nothing is credible, no information; then for those, I will definitely have to search for extra information.* [Respondent 1]
>
> *Okay, I know it is [misinformation] because I never found the information in the newspaper or news, and the Honorable Minister of Health has never allowed its usage in health.* [Respondent 9]

XSL•FO
RenderX

Social Trust and Misinformation on Social Media

In general, respondents highlighted that health misinformation mainly comes from individuals rather than organizations, and any individual could potentially spread misinformation, including vaccine opponents, family members, friends, celebrities, health care professionals, and business-oriented individuals. Furthermore, those who lack knowledge of how to obtain accurate information were considered potential sources of misinformation. Those spreading misinformation about health were described as having a strong belief in their stance:

> *They have a lot of followers, it's like cults. For example, if they post something, and you comment with scientific evidence, they will [continue to] reject because they have been brainwashed.* [Respondent 17]

> *They do not know where to find the correct information, so whatever information they get, they feel it is true.* [Respondent 20]

Respondents highlighted important characteristics related to social trust in the source of a message, which significantly influenced their perception of health misinformation. They noted that individuals who have a strong social media presence and a trustworthy image are more likely to be believed. This trust is particularly important when assessing the credibility of health information. Respondents indicated that individuals with strong educational backgrounds, professional qualifications, or verified social media profiles were seen as more reliable, thus emphasizing the image portrayed on social media being of utmost importance. Conversely, individuals lacking these credentials were viewed as less trustworthy.

Sociodemographic Influences on Source Credibility

Respondents also discussed how sociodemographic factors influenced the perceived credibility of sources of health misinformation. Education level was identified as a key factor, with respondents perceiving that people with lower educational backgrounds were more likely to spread misinformation. Geographic location, particularly rural areas, was another significant influence, with respondents believing that people in rural areas had limited access to reliable health information. Age was also mentioned, with older individuals often seen as sources of misinformation, although respondents acknowledged that misinformation could originate from any age group:

> *Those less privileged, less educated, or [from] rural areas, they tend to share a lot of fake news.* [Respondent 13]

> *Especially parents, those in their 50s, share a lot of [such information], but they don't really know whether it is true or not.* [Respondent 22]

Challenges Associated With Identification of Health Misinformation

Respondents indicated that identifying misinformation becomes difficult when a message possesses certain characteristics. These characteristics included lengthy posts and messages that spread virally. Furthermore, messages that contain anecdotes and testimonials appeared convincing, as they had been tried by many people with positive results. Similarly, messages and videos that feature endorsements from academicians or health care professionals for treatments were also deemed challenging to differentiate. Some respondents perceived that they could trust the message if it went viral. Hence, viral messages can create confusing outcomes for the general public, as some believe that the message is reliable, while others believe that it might be spreading misinformation:

> *It looks like something genuine because they include anecdotes and testimonials. They include videos like I've tried this.... So, when you have these kinds of anecdotes, people are influenced by the power of emotions.* [Respondent 2]

> *They quote doctors claiming the latest evidence shows that high cholesterol is normal, safe, and can prolong lifespan. So, the public will believe they can lead a sedentary life and consume a high-fat meal.* [Respondent 4]

Responses To Health Misinformation

Responses to health misinformation can be divided into 3 themes: ignoring, verifying health information, and taking action.

Ignoring

Many respondents disclosed that they often chose to simply ignore or disregard health misinformation and cited several reasons for this.

Some respondents mentioned that they would ignore the misinformation when they are uncertain about the health topic, if it was controversial, or if it came from unknown strangers. In addition, many respondents believed that they lacked sufficient expertise in health matters to offer informed opinions and, thus, preferred not to risk appearing ignorant on social media. Some were also concerned that challenging the misinformation might lead the perpetrator to question their qualifications, and that could backfire:

> *I want to fix [correct] it. But the netizens will comment "Who are you to tell this?" So, I leave it alone.* [Respondent 10]

> *Because we do not have the knowledge, I am a public person, so we follow those who have studied. When they argue these types of topics, we simply leave it.* [Respondent 19]

Another reason cited by respondents for ignoring health misinformation was to avoid potential trouble and conflict. They expressed concerns that challenging the perpetrator might lead to cyberbullying or negative reactions. Others expressed feelings of fear or concern about offending or embarrassing the person sharing the misinformation, which led them to refrain from challenging the content, highlighting how emotions, such as empathy, fear, and worry, influenced their decision to remain passive. Furthermore, 1 respondent highlighted that they would ignore the misinformation if there were many supporters for those sharing misinformation:

> *I will not interfere with them. If the poster [person posting the misinformation] wants to look for trouble*

XSL•FO
RenderX

> *with you or the people who follow that person are really supportive of that person, then I am going to be in trouble.* [Respondent 22]
>
> *If there are many people in the group that you do not know and you do not know how they will react, I will just ignore them. It is because I try to avoid conflict and trouble.* [Respondent 22]

A few respondents mentioned that they would ignore the misinformation when it does not affect them personally. They believed that it would require too much effort to try to correct the misinformation and that they would not be able to make a difference in any case. Some simply believed that someone else would correct it, while others felt that it was the responsibility of the government to take corrective actions:

> *A lot of people seem to believe that [misinformation]. So, you cannot really change their minds.* [Respondent 1]
>
> *It is a mentality of how much difference am I going to make?* [Respondent 7]

In addition, 1 respondent believed that the perpetrator's opinion should be respected as a form of free expression allowed on social media. They added that condemning people for their opinions is not an acceptable practice.

Verifying Health Information

Most respondents described verifying health-related information that they come across on social media and shared various reasons and methods they used to verify the information. Verification usually involves checking both the content of the information and the background of the individual or organization sharing it. Many indicated the importance of verification, even if the source of the information is a health care professional or family member:

> *When they post something, I will search about it first, even if my family members share something.* [Respondent 14]

Respondents reported that they were more likely to check information if it pertained to a serious issue that could potentially affect them. They also mentioned that they would verify information if they were uncertain about it, for instance, if the information was difficult to understand or if they had never heard about it before. They were also more likely to verify information that came from fewer sources or sources with questionable reliability and trustworthiness. In addition, respondents said that they would verify information if conflicting information was presented or if they were considering spending money, for example, on a product advertised:

> *I will check if I never heard about it before.* [Respondent 21]
>
> *I would look for more information if it affects me or I have to spend money for it.* [Respondent 3]
>
> *When they post, usually I check their backup sources, from where they share their information...At least if there is research or link to reliable sources. I do not like it when they share something not to be done, without any evidence.* [Respondent 13]

When evaluating the credibility of health-related information, respondents typically used multiple sources, including social media, health care professionals, health organizations, traditional media, family members, acquaintances, websites, and studies. Some respondents mentioned that they could identify false information because the correct information had already gone viral. If the respondents still had doubts, they simply visited a doctor to clarify the information. The respondents emphasized the importance of being vigilant and having critical thinking skills to distinguish between true and false information:

> *I will read a lot more than just Facebook. Maybe I will Google first and then read. I will read the type of feedback provided by other people.* [Respondent 17]
>
> *I will check with doctor friends, pharmacists, and nurses.* [Respondent 9]

Taking Action

This theme relates to respondents describing the actions that they would take to address health misinformation on social media. If respondents were to take action, it would be either to report, block, or correct misinformation. Respondents also discussed who should be responsible for correcting the health misinformation.

Many respondents mentioned that they would report the misinformation despite perceiving limited regulations on social media. The reporting actions included notifying relevant social media administrators; law enforcement agencies, such as the National Pharmaceutical Regulatory Agency; and the Ministry of Health. Interestingly, 1 respondent said that they would tag the police department. These efforts were aimed at ensuring the misinformation was removed from the respective social media platforms:

> *If I am sure it is wrong, there is a button where you can press report. Yeah, I will just do that.* [Respondent 14]

Some respondents indicated that they did not want to ruin their social media page with content that they disagreed with. Thus, they would either mute or block the offender's account, while others deleted those who posted misinformation from groups.

Many respondents believed that correcting misinformation is important and expressed their willingness to do so if they encounter false information. However, respondents mentioned that they were more likely to provide corrections in certain situations. Generally, they were inclined to correct misinformation if they felt there could be no conflict or direct confrontation as a result. For example, if they knew the person posting misinformation, they would feel comfortable providing corrections, driven by a sense of familiarity and trust. They felt safe correcting misinformation through personal WhatsApp messages or group chats if they were familiar with everyone in the group. In addition, respondents described feeling more confident in correcting misinformation if they were knowledgeable about the topic and if others had already

XSL•FO
RenderX

corrected it before them. They were also more motivated to provide corrections and encourage others to verify the information source if they believed it could affect their family members, indicating how emotional factors such as care and responsibility can motivate actions against misinformation:

> *If there are people close to me, for example a group of five people that I am close to, close friends, then it will be easy for me to correct them.* [Respondent 22]

> *If there are others who have commented it is wrong, then I will comment. Otherwise, I will not.* [Respondent 14]

> *If it affects my family, I would shut it down immediately. I will tell them that they would want to check the sources. But when it comes to other people, I mostly would not budge [react].* [Respondent 7]

When correcting misinformation, respondents provided justifications for why the information was false and sought to persuade using data and facts. A few respondents also mentioned using general terms and simple language, similar to that used by those disseminating false information. In addition, respondents shared information from sources deemed reliable, including social media sources with blue verification ticks, to correct misinformation:

> *Try to speak things in terms of their perspective, like put yourself in their shoes and try to speak in their language. However, if things fail, then try to convince with facts and figures.* [Respondent 2]

> *Take the evidence from the blue tick source.* [Respondent 21]

Respondents described experiencing mixed outcomes when correcting misinformation. Some family members were thankful and believed the corrected information, while others deleted the false information post. Unfortunately, some respondents faced reprimand and subsequently chose to disregard it. Despite the possibility of disbelief from others, they believed it was their duty to educate them regarding the truth. However, some respondents reported that their comments went unanswered, and in some cases, the offenders shared even more questionable links. Nevertheless, it was emphasized that respondents had done their part in correcting the inaccurate information.

Who Should Correct Health Misinformation on Social Media

The respondents believed that the government should take action against the spread of misinformation. In addition, it was suggested that the government should adopt measures to educate the general public about the dangers of misinformation and to be cautious before sharing health information on social media. Furthermore, respondents proposed enforcing legal provisions and regulations against those spreading health misinformation. An interesting suggestion was made that the Ministry of Health could use nudges on social media, such as "Are you sure about this?" to encourage the general public to consider the validity of health information before sharing it:

> *I hope the government of Malaysia will tighten the law for those who like to spread wrong information, because if they do not, they will keep doing it.* [Respondent 19]

> *For example, Ministry of Health can comment "Are you sure this fact is true?" and people will be thinking, okay this may not be true because Ministry of Health commented.* [Respondent 22]

Respondents also recommended that the Ministry of Health establish a multidisciplinary team dedicated to verifying and correcting misinformation on social media. They also highlighted an opportunity to improve accessibility by providing government health information in languages beyond English and Malay to better accommodate a multicultural population. Furthermore, participants emphasized the importance of providing timely and transparent explanations for changes in health-related information, as observed during the COVID-19 pandemic, when frequent updates were necessary because of emerging evidence:

> *They should have a team or department that targets or even tracks all these rumors being spread around.* [Respondent 7]

> *I wish they would have more languages. At this point, it is mostly in English and Malay, and there are many elderly people who do not understand.* [Respondent 7]

> *During the Covid-19 pandemic, initially they [government] provided a recommendation [on] vaccines...then they provided different information...but they never explained whether the vaccines were really effective.* [Respondent 6]

> *The public may not understand that knowledge is progressive. Initially, the government recommended two doses to achieve herd immunity, but when cases were rising, they introduced booster doses. The public will hold on to the recommendations made two years ago.* [Respondent 16]

In addition to the government, respondents also believed that health care professionals have a responsibility to combat misinformation. It was suggested that health care professionals should be more proactive in correcting misinformation on social media and consider reaching out to populations considered vulnerable:

> *Healthcare workers such as doctors and pharmacists should correct people's understanding on medication. If more people share on social media, it is better so that the wrong and true information are in the same quantity.* [Respondent 13]

> *When doctors post on health information, they have to think how to reach those susceptible to this [misinformation].* [Respondent 13]

Discussion

Principal Findings

The spread of health misinformation through social media platforms has led to uncertainty and evokes a range of emotional responses in those who encounter it. This study provides insights into the various approaches used by the general public to identify health misinformation on social media as well as the reasons and motivations behind their responses to it. In addition, several challenges faced by the general public in identifying and addressing misinformation were identified.

The first phase of TMIM describes the uncertainty caused by health misinformation. Our study reflects this, showing that misinformation spread through social media platforms led to uncertainties and triggered emotional responses, such as worry, fear, self-doubt, anger, feelings of vulnerability, disappointment, and anxiety. Studies in other countries also showed this, where misinformation in South Africa caused panic, confusion, and anxiety [53]. Similarly, studies in Jordan and Spain reported elevated levels of anxiety in response to health misinformation [13,54]. These emotions significantly influence how individuals process and respond to misleading health information. Higher levels of anxiety and fear, for example, are associated with increased belief and willingness to share misinformation [55,56]. Anger, which often arises when users feel deceived by false claims, also contributes to intuitive actions and the further spread of misinformation [57,58]. Fear and anxiety tend to intensify when misinformation relates to health threats, increasing concerns and feelings of vulnerability over personal and general public health [59]. Uncertainty and self-doubt emerge when users encounter conflicting information, leading to cognitive dissonance that hinders informed decision-making [60]. Such emotional distress can lead to a general feeling of disappointment, especially when people realize that they have been misled by trusted sources or when accurate information is overshadowed by misinformation [57]. The cumulative effect of these emotions can hinder effective health decision-making and reduce trust in health information sources [12-15]. This may influence the evaluation phase, where individuals analyze and attempt to identify health misinformation on social media platforms.

Previous research has identified both internal and external factors that individuals use to determine the credibility of the information [61-63]. Internal factors include elements such as the source of the message, message characteristics, and individual personality traits. By contrast, external factors include institutional sources or interpersonal networks, such as verification from family, friends, and trusted institutions. This study also described the internal and external factors used by respondents to assess credibility and the challenges faced in identifying misinformation. One significant internal factor is the source of the message. Trust in government and health care professionals emerged as an important component, highlighting how credibility is tied to recognized, authoritative sources. This aligns with the MAIN (modality, agency, interactivity, and navigability) model, which suggests that technological aspects of digital media can influence credibility judgments, particularly when information comes from official authorities [64]. Supporting this, a study conducted in Malaysia found that respondents mainly selected the Ministry of Health as their preferred source of health information [65]. This trust may stem from cultural norms in Malaysia, where the conservative Asian context fosters greater respect for figures of authority [66]. Furthermore, respondents believed that the government has a critical role to play in combating this problem by implementing regulations and awareness campaigns. Beyond institutional sources, respondents also expressed trust in messages from those they believed to have trustworthy reputations and relevant educational backgrounds. This was also similar in India, with respondents placing trust in messages from local government representatives and community health workers deemed to have a wide knowledge of the area [62].

In contrast to previous studies conducted in Malaysia and the United States, where most respondents were unable to evaluate the accuracy of health-related information, our study identified specific characteristics of messages that respondents associated with misinformation [67,68]. Respondents pointed out that exaggerated or illogical claims, such as those promising miracle cures, were indicative of misinformation. This was similarly seen in a survey study in Austria, where exaggerated claims were met with skepticism [69]. Conversely, social media messages that were visually appealing were often perceived as more credible by respondents. Research has indicated that visual design plays a role in influencing people's judgments about the credibility of health information found on the web [70]. This may be because of the attractive design of these messages, such as well-crafted infographics, which suggest that effort and thought have been invested in creating them, which in turn increases their trustworthiness [71].

Correction directed to those sharing the misinformation and individuals looking at misinformation was considered a strategy for combating health misinformation [30]. A content analysis of monkeypox on Instagram found that one-third of the content was debunked, with social media users actively correcting the misinformation [72]. It was interesting that in our study, many respondents chose to ignore misinformation, citing avoidance of conflict and perceived futility in correcting it. This behavior aligns with findings from another Malaysian study, which showed that most respondents tended to ignore fake news during the COVID-19 pandemic [68]. Such tendencies may be influenced by cultural norms, as previous research has found that Malaysians often prefer to avoid conflicts [73]. Nevertheless, this finding is also consistent with other studies [62,74-76], including a UK study that found avoidance of conflict to be a major barrier in preventing the correction of COVID-19 misinformation [76]. However, despite these challenges, some respondents in our study were willing to take action when their loved ones were affected or when they had a close relationship with those posting misinformation. This could be beneficial, as the literature suggests that correction by a close tie could be successful [77]. In addition, corrections that focus on collective interests have been shown to work better [78].

Respondents also were more inclined to correct misinformation when they felt that they knew the topic well. This is supported by previous studies where health care workers themselves face

XSL•FO
RenderX

challenges in correcting misinformation because of various factors, such as the belief that there would be no improvement after correction; lack of time to address the issue; fear of retaliation from those posting misinformation; and a lack of support, such as social media training, to handle these situations [79]. They opted to correct misinformation only if it was important to them or if the offender was someone close to them [74]. Furthermore, an experimental study among health experts in China showed that they were willing to correct health misinformation when the perceived threat to readers was severe, when they believed that they had the necessary skills to correct it, and when they wanted to maintain a reputation of kindness toward others [80]. This aligns with a study in India where respondents chose not to correct misinformation if they believed it would not cause harm [62].

Suggestions for Interventions to Tackle Health Misinformation

Multifaceted interventions involving multiple stakeholders, including government, health care providers, researchers, academicians, and social media administrators, are needed to effectively address health misinformation on social media. Previous studies have recommended measures to combat health misinformation in Malaysia, such as legal action against offenders, the establishment of fact-checking portals, and the continuous health information dissemination to the general public [81]. The findings from this study suggest additional measures that can be implemented to further address the spread of misinformation. Respondents identified several challenges in identifying misinformation, including those presented with anecdotes or testimonials. It has been acknowledged that misinformation can spread when compelling anecdotes are presented and data are misrepresented with fake experts [82]. Studies also revealed that correct information and misinformation both contained anecdotes, which explains why the general public may be confused in this regard [83]. This highlights the need for digital literacy training on how to search for, identify, verify, and share credible health information on social media, as indicated by other studies [84-87]. Improvement in digital literacy skills was seen to improve recognition of the quality of health information on the web [88-91]. Educational institutions should also focus on increasing awareness regarding the identification of health misinformation on social media [92-94]. This was shown to lead to fact-checking information before sharing [95].

In addition, messages that are viral need to be monitored, as they tend to cause confusion regarding credibility, as indicated by respondents in this study. Another study supports this, showing that among African American older adults, respondents were more likely to believe a message if they saw the information multiple times [96]. Furthermore, other studies have shown that health misinformation with a greater number of likes is often perceived as more credible, as it was viewed as social endorsements [18-20]. One potential strategy is to assemble a team of health experts to correct misinformation on social media and highlight the truth, with the support of multiple experts to prevent cyberbullying toward them [79,86,97]. In addition, health care workers can address health misinformation by correcting it when they encounter it with patients at clinics or in hospital settings. This can be done by educating the patients and encouraging 2-way communication between patients and health care workers [98,99]. Moreover, the government could focus on “prebunking” by addressing potential areas that could pose challenges in differentiating misinformation before it spreads [100,101]. As “prebunking” effect is limited, this strategy should be combined with other efforts to enhance its effectiveness in combating misinformation [102].

Access to multilingual health information has also been identified as a need, with potential implications for health equity. The WHO has acknowledged multilingualism as an area to improve equality in health information dissemination [103]. However, further investigation is required to determine the extent of implementation across countries and to assess the need for additional languages in health information dissemination to effectively combat misinformation.

Limitations

This study offers insights into public perceptions of health misinformation on social media in a Southeast Asian country, a region with limited research on the topic. The challenges described can be used to develop interventions to address the issue of health misinformation on social media. Nevertheless, this study has some limitations that need to be considered, including the possibility of sampling biases and social desirability biases. Although efforts were made to include a wide range of respondents from various sociodemographic backgrounds, it is possible that certain groups may have been missed, such as those with lower educational backgrounds or older respondents. Further quantitative research is recommended to better understand how different population groups identify and respond to health misinformation. The development and validation of tools to measure this, such as survey-based approaches to validate identified themes, would be valuable for enabling cross-country comparisons regarding responses to health misinformation.

Conclusions

The characteristics of a message and its source on social media are important factors that the public considers when identifying health misinformation. Various reasons and circumstances may affect individual responses toward health misinformation, which range from ignoring it to verifying health information and adopting measures to correct it. Digital literacy training may be useful in addressing the challenges faced by the public in identifying and responding to health misinformation. This study also highlights the need to further investigate populations considered vulnerable or at risk of health misinformation on social media and the factors influencing responses toward health misinformation, which will allow the development of targeted intervention strategies.

Abstract

Background: Dengue fever has evolved into a significant public health concern. In recent years, short-video platforms such as Douyin have emerged as prominent media for the dissemination of health education content. Nevertheless, there is a paucity of research investigating the quality of health education content on Douyin.

Objective: This study aimed to evaluate the quality of dengue videos on Douyin.

Methods: A comprehensive collection of short videos pertaining to dengue fever was retrieved from the popular social media platform, Douyin, at a designated point in time. A systematic analysis was then performed to extract the characteristics of these videos. To ensure a comprehensive evaluation, three distinct scoring tools were used: the DISCERN scoring tool, the JAMA benchmarking criteria, and the GQS method. Subsequently, an in-depth investigation was undertaken into the relationship between video features and quality.

Results: A total of 156 videos were included in the analysis, 81 of which (51.9%) were posted by physicians, constituting the most active category of contributor. The selected videos pertaining to dengue fever received a total of 718,228 likes and 126,400 comments. The video sources were categorized into four distinct classifications: news agencies, organizations, physicians, and individuals. Individuals obtained the highest number of video likes, comments, and saves. However, the findings of the study demonstrated that physicians, organizations, and news agencies posted videos are of higher quality when compared with individuals. The integrity of the video content was analyzed, and the results showed a higher percentage of videos received a score of zero points for outcomes, management, and assessment, with 69 (45%), 57 (37%), and 41 (26%), respectively. The median Total DISCERN scores, JAMA, and GQS of the 156 dengue-related videos under consideration were 26 (out of a total of 80 points), 2 (out of a total of 4 points), and 3 (out of a total of 5 points), respectively. Spearman correlation analysis was conducted, revealing a positive correlation between video duration and video quality. Conversely, a negative correlation was observed between the following variables: video comments and video quality, and the number of days since posting and video quality.

Conclusions: This study demonstrates that the quality of short dengue-related health information videos on Douyin is substandard. Videos uploaded by medical professionals were among the highest in terms of quality, yet their videos were not as popular. It is recommended that in future, physicians employ more accessible language incorporating visual elements to enhance the appeal and dissemination of their videos. Future research could explore how to achieve a balance between professionalism and entertainment to promote user acceptance of high-quality content. Moreover, platforms may consider employing algorithmic optimization or content recommendation mechanisms to encourage users to access and engage with more high-quality health science videos.

Introduction

The dengue virus (DENV) is considered to be among the most significant mosquito-borne pathogens, and it was listed among the top 10 global health threats in 2019 [1]. The dengue virus can cause a wide range of clinical manifestations, varying from a relatively minor illness characterized by flu-like symptoms and known as dengue fever (DF) to a condition that carries a significant risk of mortality and is known as dengue shock

syndrome (DSS). The 2009 World Health Organization (WHO) classification system for dengue is predicated on the levels of severity. The system includes the following classifications: dengue without warning signs, dengue with warning signs (which includes abdominal pain, persistent vomiting, fluid accumulation, mucosal bleeding, lethargy, liver enlargement, and increasing hematocrit with decreasing platelets), and severe dengue, which includes dengue with severe plasma leakage, severe bleeding, or organ failure [2]. A 30-fold increase in dengue incidence has been seen in the last 50 years, and more than 50% of the world's population, in over 100 countries, is living in areas at risk of DENV infection [3,4]. It is evident that in 2023, the number of reported infections worldwide exceeded five million, resulting in approximately five thousand deaths, which approximates a historic peak [5]. These data indicate that dengue fever is a significant global public health concern, necessitating the implementation of effective control and prevention strategies.

The emergence of dengue fever in China poses a considerable risk to public health and social stability. An outbreak of dengue fever occurred in Guangdong in 1978, resulting in a total of 22,122 cases of infection and 16 deaths. Since then, dengue has been identified annually, with outbreaks occurring intermittently at 4 - 7-year intervals [6,7]. A comprehensive review of the extant literature reveals that from 1978 to 2019, dengue fever outbreaks led to a total of 747,417 cases and 622 deaths [1]. These alarming figures not only reflect the widespread spread of dengue fever in the country, but also reveal the challenges faced in preventing and controlling the disease. The implementation of efficacious prevention and control strategies is imperative to mitigate the societal burden of dengue fever and to protect public health and safety.

The outpatient management of dengue fever by primary care physicians represents the primary treatment strategy, as the majority of cases present as mild and self-limiting [8]. It is standard practice to advise patients with dengue who are being treated on an outpatient basis to seek immediate medical assistance when warning signs of dengue are present. The prevention of dengue virus infection requires the acquisition of knowledge, the development of favorable attitudes and the adoption of appropriate practices among the general public [9]. The absence of awareness regarding the transmission of the dengue infection and the preventive measures that can be employed to avoid infection may elevate the risk of disease transmission. A study conducted in China demonstrated that the Dai people possess a comprehensive understanding of dengue fever. However, their perceptions of disease susceptibility and severity are relatively low [10]. Recent research has demonstrated that, despite the efforts of physicians to educate their patients about warning signs and their significance, many patients either lack recall or fail to fully comprehend these messages. Consequently, it is imperative to enhance public cognizance and comprehension of dengue fever and to furnish precise counsel on prevention. This is an indispensable strategy for controlling and preventing the dissemination of dengue fever.

The dissemination of information through various forms of mass media, including official WeChat accounts, print media, leaflets, broadcast media, and the Internet, directly influenced the public's knowledge about dengue fever and their actions regarding mosquito control [11]. As indicated in the 50th Statistical Report on China's Internet Development Status, published by the China Internet Network Information Center, the nation's Internet penetration rate was 74.45% as of June 2022, with 1.051 billion Internet users [12,13]. The number of users of short videos has increased markedly in recent years, reaching approximately 962 million users across the country [12]. TikTok, a video-sharing medium, has amassed a user base of 600 million in China alone [14]. It has been reported that as of July 2020, TikTok's videos pertaining to the novel coronavirus were viewed a total of 93.1 billion times during the ongoing pandemic [15]. Nevertheless, a considerable body of research has demonstrated that approximately half of the videos shared on the social media platform TikTok disseminate misinformation or present a deficient level of expertise [16,17].

A substantial number of videos related to dengue fever were identified on the Chinese version of the video-sharing platform TikTok. Nevertheless, the reliability of the information provided remains questionable. The objective of this study was to evaluate the quality of information presented in videos related to dengue fever that are available on the Chinese version of the social media platform.

Methods

Data Collection

In this cross-sectional study, the Chinese version of TikTok, known as Douyin, was queried on November 23, 2024, for the specific term "dengue fever" in Chinese. The videos were sorted by a comprehensive ranking with the publishing time set to unlimited, which represents the default setting on TikTok. This analysis focused on videos that addressed dengue fever directly. However, videos pertaining to other topics, in addition to commercials, videos in languages other than Chinese, duplicate videos, videos of personal experiences and videos lacking audio, were excluded from the study. A total of 324 videos pertaining to dengue fever were identified on the Douyin platform, of which 156 were selected for further data extraction and analysis following a rigorous screening process.

The following characteristics of each Douyin video pertaining to dengue fever were recorded and subsequently subjected to a comprehensive analysis, including the title, content, quantity of likes and comments, number of saves, days since upload, duration of video, and status of video source, such as the number of fans and likes for the uploader. All relevant data were stored in a Microsoft Excel spreadsheet.

Classification of Videos

Video sources were classified into the following categories: (1) News agencies, including network platforms, print media, television, and radio stations; (2) Organization entities such as healthcare facilities, public health agencies, research teams, and academic institutions; (3) Physicians; and (4) Individuals, especially those without professional medical qualifications.

XSL•FO
RenderX

Quality Assessment

The quality of the video content was evaluated using three distinct assessment instruments: the DISCERN instrument (Table S1 in Multimedia Appendix 1), the benchmark criteria established by the Journal of the American Medical Association (JAMA) (Table S2 in Multimedia Appendix 1), and the Global Quality Scores (GQS) (Table S3 in Multimedia Appendix 1). A systematic review indicates that, since its publication in 1998, DISCERN has become one of the most frequently employed instruments for evaluating the quality of health information [18]. In recent times, it has been utilized to assess the quality of information conveyed in health education videos [19,20]. The instrument is comprised of 16 items, with response options anchored on a 5-point rating scale, ranging from 1 (indicating poor performance) to 5 (indicating good performance). The 16-item scale is divided into three sections. The first section concerns the reliability of the publication and comprises eight items. The second section evaluates the quality of information regarding treatment choices and comprises seven items. The third section requests an overall rating of the publication, which is based on a single item [21]. The DISCERN scores spanned from 16 to 80, with classifications as follows: very poor (16-26), poor (27-38), fair (39-50), good (51-62), and excellent (63-80) [22].

The JAMA benchmark criteria were employed to evaluate the reliability of the video source. The aforementioned criteria are constituted of four individual criteria, which are as follows: (1) providing authorship; (2) listing copyright information and references, as well as sources of content; (3) providing the initial date and subsequent updates; and (4) disclosing conflicts of interest, funding, sponsorship, advertising support, and video ownership. The total possible score is four points, with each criterion accounting for one point, respectively [23]. Furthermore, the GQS was utilized to assess the quality of the educational content, with a specific focus on evaluating the quality of the material, the comprehensiveness of the information presented, and its utility for patients. The instrument yielded scores on a scale ranging from one (which indicates poor quality) to five (which indicates excellent quality and flow) [21]. Jun Qiu and Youlian Zhou, both Master of Medicine and critical care medicine department members, served as the raters. The determination of the scores was conducted through a process of discussion, and an arbitrator, Liang Yang, a highly qualified critical care physician, was appointed to resolve conflicts between raters and to issue the final scores. Subsequently, all authors achieved a consensus on the ratings.

Completeness of Content

In order to evaluate the completeness of the video content, six questions from the study conducted by Goobie et al were adopted [24]. The aforementioned six questions inquire as to the extent to which a given video addresses the following elements: definitions of diseases, their signs and symptoms, risk factors, evaluations, management strategies, and outcomes. Each component was evaluated using a three-point scale, with a value of zero assigned to those that were not addressed, one to those that were partially addressed, and two to those that were fully addressed.

Statistical Analyses

In cases of categorical variables, the reported values are the count and percentage. The distribution of continuous variables does not align with the normality assumption. To address this, we express the descriptive statistics for continuous variables using the median and interquartile range. The Kruskal-Walli's test was employed to evaluate the existence of statistically significant differences between multiple groups. Subsequently, the Dunn multiple comparisons test was utilized to facilitate intergroup comparisons. The interobserver agreements were assessed using intraclass correlation coefficients (ICC). The relationships between the quantitative variables were evaluated using Spearman correlation analysis. A *P* value of less than .05 was deemed to be statistically significant. The data were analyzed using the SPSS (version 27; IBM Corp) software and GraphPad Prism (version 10 for Mac).

Ethical Considerations

No human biospecimens or experimental organisms were used in this study. As the study focused only on digital content analysis, the institutional ethics committee did not consider it necessary to conduct a review.

Results

Video Sources

A total of 156 videos were included in the analysis, 81 (51.9%) were posted by physicians, constituting the most active category of contributor. News agencies were the second most active category, posting 34 (21.8%) videos. Individuals posted 33 (21.2%) videos, while organizations posted the fewest, with 8 (5.1%) videos (Table 1).

Table . Distribution of video sources.

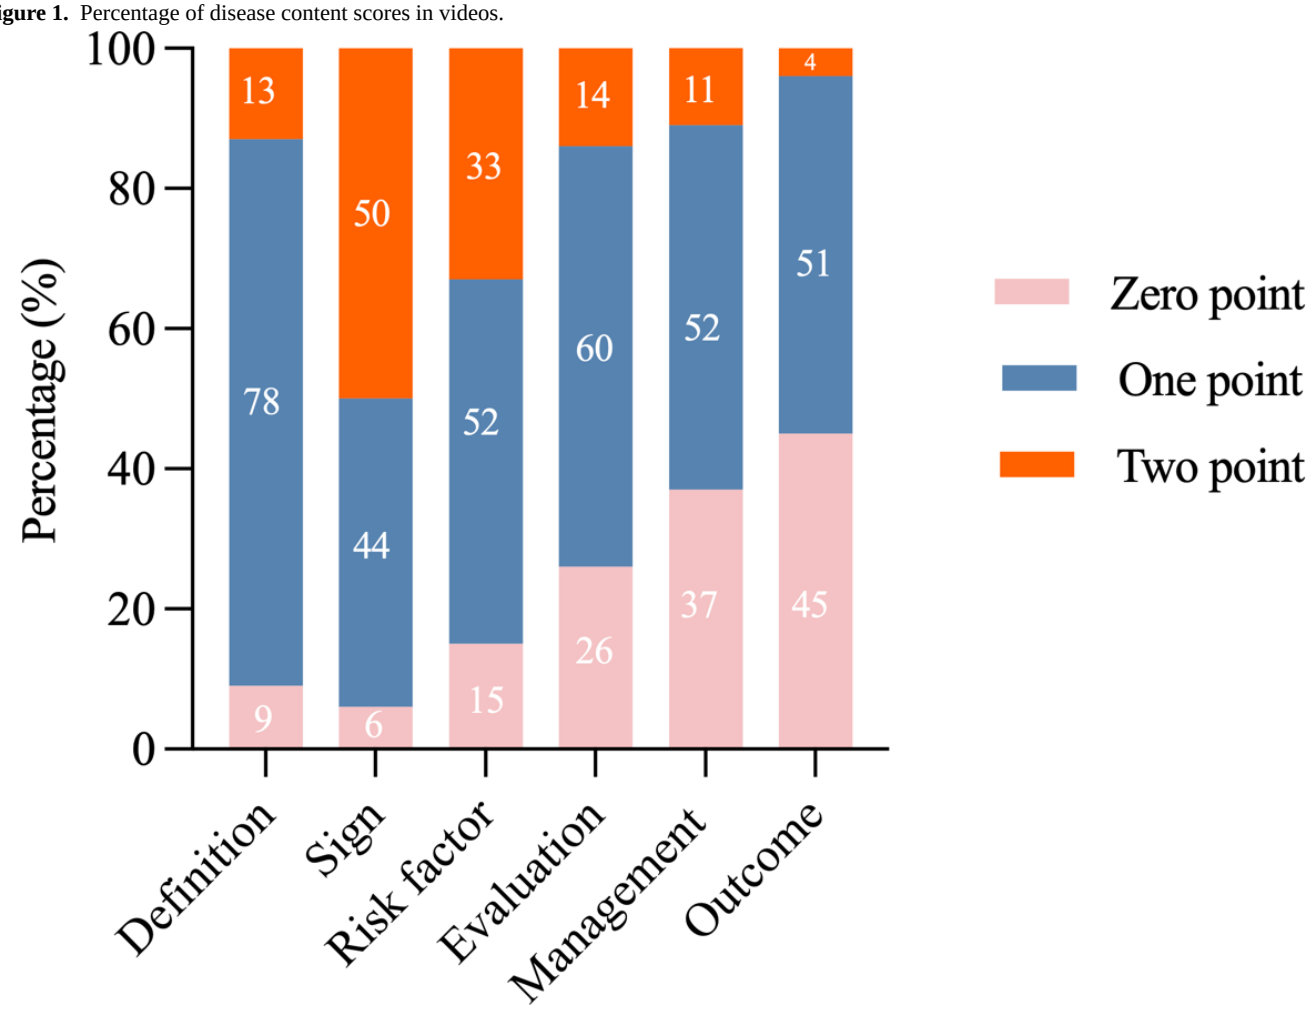
Video sources	Values, n (%)
Physicians	81 (51.9)
News agencies	34 (21.8)
Individuals	33 (21.2)
Organizations	8 (5.1)

XSL•FO
RenderX

Basic Characteristics of Videos

The selected video pertaining to dengue fever received a total of 718,228 likes and 126,400 comments. The most recent video relevant to this subject was uploaded one day before the collection of data, while the oldest was uploaded 1190 days prior to data collection. The average number of days since upload was 89 (SD166). The duration of the videos exhibited significant variation, with the longest video lasting 421 seconds and the shortest video lasting 12 seconds. The mean video duration was 86 (SD 66) seconds. The highest number of fans and likes for the uploader was observed for news agencies, while the lowest was recorded for organizations. Individuals obtained the highest number of video likes, comments, and saves. The number of days since video was uploaded, and the length of the video, were longest for individuals, followed by physicians and news agencies, and lastly, organizations (see Table 2).

Table . Basic characteristics for Douyin of different sources.



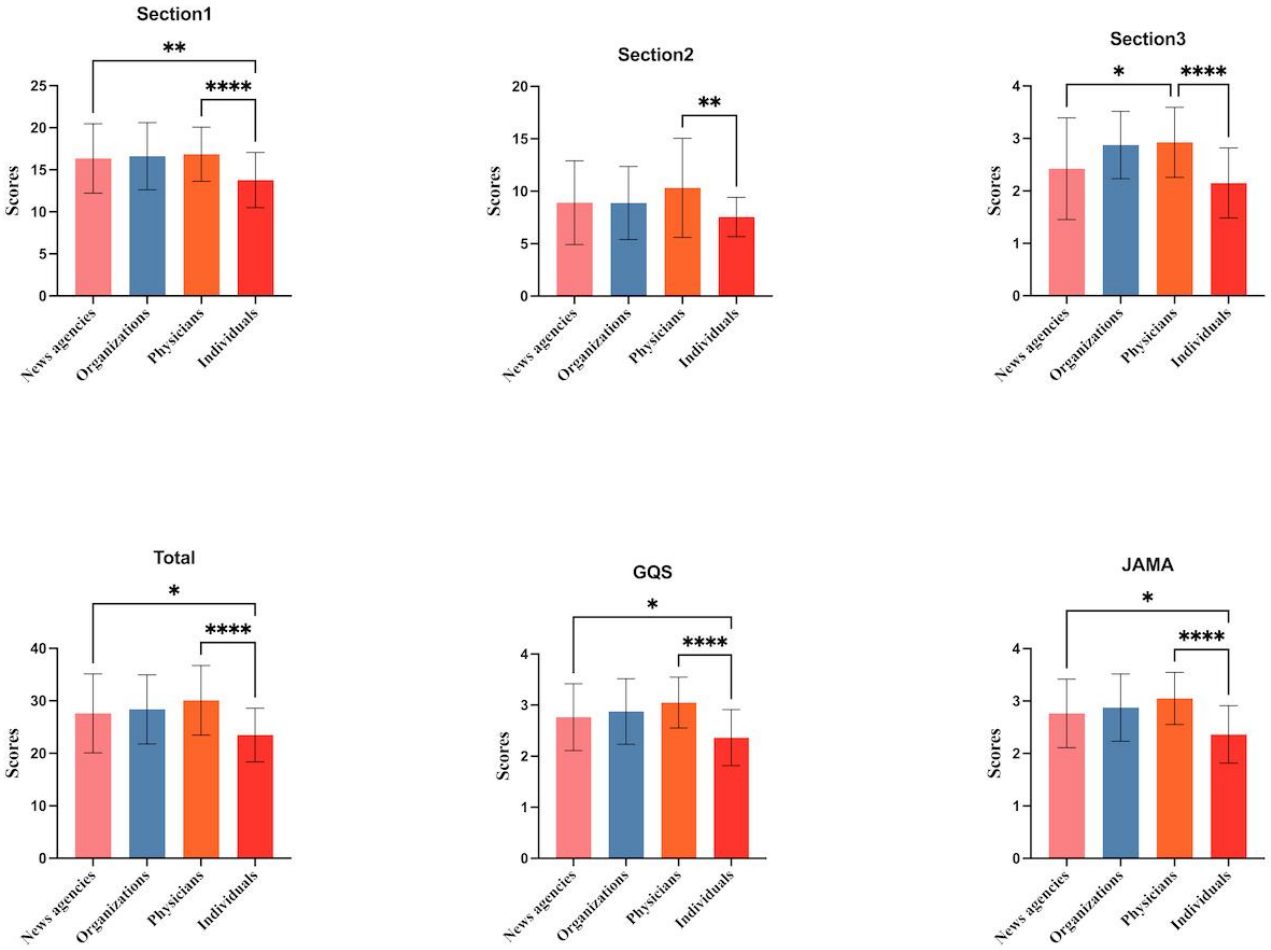
Video sources	Account fans	Account likes	Video likes	Video comment	Video saves	Days since upload (d)	Duration (sec)
News agencies, median (IQR)	386500.00 (69250.00-2827500.00)	3997500.00 (365500.00-48277500.00)	328.00 (129.00-2894.50)	19.50 (1.50-243.50)	99.00 (12.25-619.50)	27.54 (12.39-134.47)	57.00 (28.00-102.75)
Organizations, median (IQR)	17500.00 (1900.75-42000.00)	125500.00 (17145.75-348000.00)	102.00 (19.75-821.50)	41.00 (1.75-222.25)	22.00 (7.50-200.75)	21.96 (15.10-46.39)	55.00 (19.50-78.00)
Physicians, median (IQR)	42000.00 (13000.00-598000.00)	334000.00 (71000.00-3704000.00)	413.00 (52.00-1990.00)	30.00 (3.00-127.00)	77.00 (16.00-400.00)	26.29 (16.17-69.31)	71.00 (47.00-92.00)
Individuals, median (IQR)	22000.00 (3720.00-156000.00)	189000.00 (22000.00-1964000.00)	668.00 (176.00-1860.00)	97.00 (26.00-361.00)	114.00 (39.00-299.00)	44.07 (18.41-210.27)	85.00 (40.00-110.00)

Content of Videos

With the exception of symptoms, videos received a majority score of one point for definitions, risk factors, assessment, management, and outcomes. In regard to symptoms, 78 (50%) of the video content received a score of two points, indicating that the majority of the videos fully refer to the clinical manifestations of the disease. Notably, a higher percentage of videos received a score of zero points for outcomes, management, and assessment, with 69 (45%), 57 (37%), and 41 (26%), respectively (Figure 1).

XSL•FO
RenderX

Figure 1. Percentage of disease content scores in videos.



Video Quality Assessments

The inter-observer reliabilities for the DISCERN, JAMA and GQS demonstrated excellent reliability, with ICC values of 0.973, 0.919, and 0.898 respectively. In this study, the median Total DISCERN scores, JAMA, and GQS of the 156 dengue-related videos under consideration were 26, 2, and 3, respectively. A comparative analysis was conducted on the scores of videos from various sources employing different rating scales. In DISCERN section 1, physicians and news agencies demonstrated significantly higher scores compared to individuals (P<.0001 and P<.01, respectively). Similarly, in DISCERN section 2, physicians exhibited significantly higher scores compared to individuals (P<.01). In DISCERN section 3, physicians' scores were found to be significantly higher than both individuals' and news agencies' scores (P<.05). Additionally, the organization's score was found to be significantly higher than individuals' scores (P<.05). Furthermore, a statistically significant discrepancy was observed in the physician's DISCERN total score when compared to that of the individuals (P<.001). Likewise, a significant disparity was noted in the DISCERN total score of the new agency when contrasted with that of the individuals (P<.05). A general trend indicates that the quality of dengue video information from professional sources is higher than that obtained from non-professional sources, particularly sources from individuals.

Moreover, the physician and news agency scores were found to be significantly higher than those of individuals with respect to GQS and JAMA scores (P<.05). In sum, the findings of the study demonstrated that physicians, organizations, and news agencies obtained consistently elevated scores when compared with individuals (see Figure 2).

XSL•FO
RenderX

Figure 2. Quality score for Douyin videos of different sources. GQS: Global Quality Scale; JAMA: Journal of the American Medical Association. *P<.05, **P<.01, ***P<.001, ****P<.0001.

Correlation Analysis

A subsequent Spearman correlation analysis was conducted, revealing a positive correlation between video duration and DISCERN Section 1, DISCERN Section 3, DISCERN Total Score, and GQS (r=0.384, P<.001; r=0.279, P<.001; r=0.300, P<.001; and r=0.399, P<.001, respectively). In contrast, a negative correlation was observed between the following variables: video comments and DISCERN Section 1 (r=−0.163, P=.04), video comments and DISCERN Total Score (r=−0.222, P=.005), and video comments and JAMA (r=−0.229, P=.004). Furthermore, a negative correlation was identified between the number of days since posting and the following scores: DISCERN Section 1 (r=−0.192, P=.02), DISCERN Section 2 (r=−0.245, P<.002), DISCERN Total Score (r=−0.251, P=.002), and JAMA (r=−0.402, P<.001) (Table 3).

[a]GQS: Global Quality Scale.

[b]JAMA: Journal of the American Medical Association.

As demonstrated in Table S4 in Multimedia Appendix 1 clear linear relationship is evident between the video baseline features. The investigation revealed that the number of followers and the number of likes for the uploader were positively associated with the number of likes, comments, favorites, and posting time for the video. Furthermore, a positive correlation was observed between the number of likes, comments, and favorites for a video, while all three were positively correlated with posting time; all *Ps* <.01 (Table S4 in Multimedia Appendix 1).

Discussion

Principal Findings

TikTok, a popular short-form video platform, has amassed a substantial user base by offering innovative content, accurate recommendations, and social interaction features. Recent research has highlighted the potential of TikTok as a significant source of health information for consumers [25]. Dengue fever, an arboviral infection transmitted by mosquitoes, is endemic in tropical and subtropical regions. The dengue virus is classified into four distinct serotypes, and reinfection with different serotypes can lead to severe manifestations, including death [26]. This study was conducted for the purpose of analyzing videos pertaining to dengue fever that have been uploaded to the Chinese version of TikTok, which is known as Douyin. To assess the quality of the videos, the study utilized a variety of evaluation metrics, including DISCERN, GQS, and JAMA scores. In addition, the content of the videos was evaluated by focusing on six aspects of the disease. The videos related to dengue fever that were included in the study received a total of 718,228 likes and 126,400 comments, suggesting that Douyin has the potential to serve as a platform for disseminating health-related information and educating the public.

In this study, physicians were responsible for 81 (51%) of the dengue videos identified on Douyin, while individuals were responsible for 33 (21.2%) of the videos. However, it was observed that videos shared by individuals received more likes, comments, and favorites, which is consistent with previous research [27]. The following reasons are postulated as possible explanations for the observed phenomenon. First, videos from individuals may be more emotionally resonant or entertaining, and therefore more engaging. Second, individuals' videos tend to use more colloquial language and vivid expressions that are easier to understand. Third, viewers are more likely to watch lighthearted and entertaining content than serious expertise, and videos from individuals are more in line with this preference. A salient feature pertains to the content scores, which reveal that the majority of the videos addressed the disease's definition,

XSL•FO
RenderX

symptoms, and risk factors; however, it is noteworthy that approximately one-quarter to one-half of the videos conspicuously omitted information concerning assessment, management, and outcomes. This phenomenon aligns with prior research, which revealed that between 12.2% and 44.4% of heatstroke videos on TikTok omitted crucial information regarding assessment, management, or outcomes [20]. Two potential explanations emerge. First, the brevity of Douyin videos, with an average duration of 86 seconds, poses challenges in addressing complex subjects such as disease assessment, management, and outcomes. However, the concise nature of the platform is conducive to the effective exposition of symptoms, definitions, and risk factors. Secondly, a considerable proportion of Douyin content creators are not healthcare professionals (with only 81 (51%) of content creators being physicians) and may not possess the expertise to thoroughly assess, manage, or report on disease-related outcomes. Moreover, the communication of this expertise in a comprehensible manner is also challenging.

This analysis reveals that the overall quality of videos on the Douyin platform is substandard, a finding that aligns with the conclusions of earlier research on gallstone disease videos on TikTok and orthodontic retention videos on the platform [28,29]. A significant discrepancy was identified between the highest and lowest scores obtained by physicians and individuals, respectively, in both the DISCERN section and the total scores when comparing the quality of videos from different sources. This observation was consistent across various evaluation metrics, including the GQS and JAMA scores. Fei Sun's article revealed that individuals scored significantly lower than physicians in both the DISCERN section and the total scores [28]. Additionally, Nannan Cui et al article found that videos from physicians received higher GQS scores compared to videos from individuals [15]. A similar conclusion was reached in a study by Riccardo D'Ambrosi et al, who noted that the majority of videos exhibited low educational value, while videos posted by medical physicians exhibited higher educational value across all scores (JAMA, GQS, and DISCERN) [30]. Despite the fact that medical physicians achieved optimal results in comparison with other sources, it is important to note that the overall quality of the videos produced by medical physicians is not of a high standard. A preliminary analysis of the fundamental characteristics of the videos indicates that their brevity may be a contributing factor.

The findings of the study indicated a negative correlation between the temporal distance between video publication and analysis and quality, with the duration of the video exhibiting a positive correlation with quality. It is evident that the content of videos pertaining to medical issues may become outdated over time, particularly as medical knowledge undergoes rapid advancement. The information contained within older videos may become obsolete or no longer applicable, resulting in a deterioration in quality. Furthermore, shorter videos frequently exhibit deficiencies in both the quantity of information presented and the depth of their narrative, resulting in substandard production quality. These observations are consistent with the findings reported in previous studies [31]. A negative correlation has been demonstrated between the popularity of a video, especially its comments, and the video's quality. Previous studies have indicated that unreliable videos exhibit higher user engagement metrics [32,33], findings that are consistent with the conclusions of this study. This phenomenon can be attributed to several factors. First, the presence of exaggerated or emotional content in low-quality videos is more likely to elicit an emotional response from the user, thereby increasing the number of comments. Second, the complexity of higher quality videos may require more time for users to process, thus leading to less frequent commenting. In contrast, lower quality videos are perceived as simple, prompting immediate and frequent reactions.

A positive correlation was identified among video likes, comments, and favorites, which are indicators of video popularity. In addition, the number of followers and likes of the uploader was found to be positively correlated with the other three variables. It is evident that content creators with a considerable number of followers typically possess a greater degree of influence, achieving a higher degree of content dissemination and a broader audience reach. Moreover, content creators who have amassed a significant following demonstrate a higher propensity to engage with their audience. Consequently, these creators are more likely to garner a greater number of likes, comments, and favorites on their videos. On the other hand, users tend to interact with videos that have already received a substantial number of likes, comments, and favorites. This phenomenon, known as the social proof effect, serves to further reinforce the positive correlation between these metrics.

The application of the DISCERN instrument revealed notably low scores in the two initial sections (reliability and treatment information), a phenomenon that is likely attributable to a fundamental misalignment between the tool's design and the inherent characteristics of short-form visual media. The original development of DISCERN was for the purpose of evaluating comprehensive health information resources, and it emphasizes detailed assessments of evidence quality, alternative treatment options, and risk-benefit analyses. These elements are inherently constrained by the brevity and format limitations of short videos. While DISCERN remains a validated measure for assessing information quality in traditional formats, the findings of this study suggest that its conventional criteria may require modification to account for the unique communicative priorities of short-form platforms, where engagement and conciseness often supersede exhaustive detail. It is recommended that future adaptations of the scale consider incorporating metrics that are better suited to evaluating the accuracy and effectiveness of condensed health messaging.

The creation of a more extensive, widely viewed and high-quality corpus of disease knowledge videos will require the involvement of a greater number of healthcare professionals and specialized content creators. In addition, medical professionals and professional organizations should be incentivized to amass supporters through operating accounts and leverage the fan base to augment the dissemination of high-quality content. Concurrently, platforms should strengthen content review and quality control measures and recommend reliable, high-quality disease knowledge through optimized algorithms. In order to create high-quality videos, platforms

XSL•FO
RenderX

need to support the development of videos with comprehensive content, extend the length of videos, and ensure timely content updates. Additionally, platforms should prioritize user education to promote scientific communication and disseminate health knowledge.

This study is subject to several limitations. Primarily, the content on Douyin is subject to rapid and continual updates, which may preclude the identification of long-term trends. Secondly, the evaluation of quality is inherently subjective. Thirdly, it is important to note that this study exclusively focused on the quality of content on the social media platform Douyin and did not consider other social media platforms or artificial intelligence.

Conclusion

A cross-sectional study of dengue videos on Douyin revealed that medical professionals uploaded the highest number of videos; however, the overall quality was unsatisfactory. The number of followers of the creator is associated with the popularity of short videos, while the quality of video content is relatively weakly associated with dissemination. The health education information on Douyin is not rigorous enough to guide the public to make accurate judgments, as there are no experts to guide and supervise the accuracy of the content. In the current landscape, with the proliferation of self-media platforms and the advancements in artificial intelligence technology, there has been a significant surge in public access to health information. However, the quality of this information is highly variable, prompting the government to consider the implementation of a regulatory system, an audit mechanism, a professional certification system, and network communication standards. The implementation of these measures is intended to ensure the scientific integrity and accuracy of health information, to safeguard the public's health rights and interests, and to establish a scientific and authoritative health knowledge dissemination system.

Abstract

Background: Stroke has become a leading cause of death and disability worldwide, resulting in a significant loss of healthy life years and imposing a considerable economic burden on patients, their families, and caregivers. However, despite the growing role of online videos as an emerging source of health information, the credibility and quality of stroke prevention education videos, especially those in Chinese, remain unclear.

Objective: This study aims to assess the basic characteristics, overall quality, and reliability of Chinese-language online videos related to public health education on stroke prevention.

Methods: We systematically searched and screened stroke prevention–related video resources from 4 popular Chinese domestic video platforms (Bilibili, Douyin, Haokan, and Xigua). General information, including upload date, duration, views, likes, comments, and shares, was extracted and recorded. Two validated evaluation tools were used: the modified DISCERN questionnaire to assess content reliability and the Global Quality Scale (GQS) to evaluate overall quality. Finally, Spearman correlation analysis was conducted to examine potential associations between general video metrics and their quality and reliability.

Results: After searching and screening, a total of 313 eligible videos were included for analysis: 68 from Bilibili, 74 from Douyin, 86 from Haokan, and 85 from Xigua. Among these, 113 (36.1%) were created by health care professionals, followed by news agencies (n=95, 30.4%) and general individual users (n=40, 12.8%). The median scores for the modified DISCERN and GQS were 2 and 3, respectively, suggesting that the included stroke prevention–related videos were relatively unreliable and of moderate quality. Most videos focused on primary stroke prevention and commonly recommended adopting a healthy diet; engaging in physical activity; and managing blood pressure, glucose, and lipid levels. Additionally, videos with longer durations and more comments tended to be more reliable and of higher quality. A positive association was also observed between video quality and reliability.

Conclusions: Overall, the quality and reliability of Chinese-language online videos as a source of stroke prevention information remain unsatisfactory and should be approached with caution by viewers. To address this issue, several measures should be implemented, including establishing an online monitoring and correction system, strengthening the video review process through collaboration with health care professionals, and encouraging more selective and cautious sharing of controversial content. These steps are essential to help curb the spread of online misinformation and minimize its ongoing impact.

KEYWORDS

credibility; quality; online video; stroke; prevention; public health education

Introduction

Stroke, which is primarily classified into ischemic and hemorrhagic types, is an extremely lethal and disabling neurological disease, accounting for approximately 7.3 million deaths and 160.5 million years of healthy life lost worldwide in 2021 alone [1]. China, as one of the largest developing countries, faces an increasingly severe challenge from the burden of stroke due to its large population and rapid aging [2].

In the pursuit of better combating this growing threat, the primary prevention of first stroke and secondary prevention of recurrent stroke have emerged as critical strategies and are now recognized as essential components of global stroke control [3,4]. As a result, prevention-oriented public and patient

XSL•FO
RenderX

education is increasingly emphasized, with various specific educational methods, such as standardized courses [5], peer education [6], and community-based programs [7], proven to significantly improve stroke management quality and help mitigate rising medical expenditures.

Over the past few decades, the continuous development of the internet and the growing ownership of mobile devices have inevitably created new opportunities for education on cerebrovascular disease. In particular, online video-sharing platforms, known for their easy accessibility and user-friendly interfaces, have significantly transformed how health information is disseminated and accessed by the public [8,9]. Compared with traditional educational methods involving 1-on-1 teaching and print materials, online video-based disease education may offer a distinct advantage by presenting graphical content that is easier for audiences to absorb and retain. For example, YouTube (Google LLC/Alphabet Inc) has been found to provide useful video resources that compile information about stroke treatment options for patients and their families [10].

However, despite these benefits, the drawbacks of online video-based patient education cannot be ignored. Videos created by amateurs may contain numerous rumors, hoaxes, and misinformation that lack a solid scientific basis [11,12]. Consequently, it remains an arduous and complicated task for most patients with stroke and general users to fully evaluate the overall quality and reliability of stroke-related videos automatically recommended by search engines [13]. Given that Google (Alphabet Inc) has withdrawn its operations from Mainland China, YouTube has been unavailable to the majority of the Chinese population since 2010. Nevertheless, some Chinese domestic video-sharing platforms, such as TikTok (ByteDance Ltd), have gained tremendous popularity across the nation with their engaging content and user interaction.

Although several previous studies have investigated the quality of stroke-related materials on YouTube, TikTok, and similar platforms, showing variable reliability and adherence to evidence-based information, most of this literature originates from English-speaking contexts [10,14-17]. For instance, a systematic review by Garg et al [18] assessed social media's role in stroke education globally, while other studies have evaluated video content acquired in countries such as India [14] and Turkey [17]. However, research focusing on Chinese-language video content remains limited, despite the heavy burden of stroke and the widespread use of social media in China.

Therefore, our research team aimed to systematically assess the overall quality and reliability of online videos related to stroke prevention in Mainland China by searching for and extracting relevant Chinese-language videos from the 4 most popular online video platforms. This study seeks to address the existing academic gap and help future viewers more appropriately select stroke-related video resources.

Methods

Search Strategy

In this cross-sectional study based on electronic media, the following search terms were used: "中风" "脑卒中" (Chinese for "stroke"), "脑梗死" (Chinese for "ischemic stroke"), "脑出血" (Chinese for "hemorrhagic stroke"), and "预防" (Chinese for "prevention"). These terms were used to retrieve the top 100 videos automatically recommended by the default overall ranking on 4 popular Chinese-language online video-sharing platforms: Bilibili (Bilibili Inc/Shanghai Hode Information Technology Co, Ltd/Sony Group Corporation) [19], Douyin (ByteDance Ltd) [20] (the Chinese counterpart of TikTok), Haokan Video (Baidu, Inc) [21], and Xigua Video (ByteDance Ltd) [22]. A brief introduction to these 4 Chinese-language video platforms is provided in Table 1.

Table . A brief introduction to Bilibili, Douyin, Haokan Video, and Xigua Video.

Online video platform	History and introduction
Bilibili	Founded by Shanghai Kuanyu Digital Technology on June 26, 2009, Bilibili has become a cultural community and video platform known for its bullet comment feature and strong popularity among China's younger generation.
Douyin (Chinese counterpart of TikTok)	Founded by ByteDance in 2016, Douyin (the Chinese counterpart of TikTok) is a short video platform aimed at young audiences in China. It encourages users to record and share their daily lives using smartphones or other available filming equipment.
Haokan Video	Founded by Baidu in December 2017, Haokan Video is currently positioned as the "Comprehensive Short Video Flagship" among Baidu's products. The platform is committed to developing a broad short video ecosystem that spans knowledge, lifestyle, health, culture, history, science popularization, technology, emotions, news, film, television, and other domains.
Xigua Video	Founded by ByteDance in 2017, Xigua Video has become a leading domestic professional + user-generated content platform in China. It delivers high-quality content to diverse audiences through personalized recommendations, while promoting creative diversity and making it easy for users to share their videos.

XSL•FO
RenderX

The selection of search keywords was based on both medical terminology and commonly used lay terms for stroke within the Chinese context to ensure relevance and comprehensiveness. This approach aimed to capture a broad spectrum of videos that users might realistically encounter. For example, we included both formal terms such as "脑卒中" (formal medical terminology for "stroke" in the Chinese language) and more colloquial expressions such as "中风" (colloquial description of "stroke" in the Chinese language), which are widely used in public discourse and online media. In addition, we referred to trending tags and frequently searched phrases related to stroke on Chinese video-sharing platforms to enhance the validity of the search keyword set.

With regard to the automatic recommendation and ranking algorithm, consultation with the customer service agents from the selected platforms indicated that the algorithms are primarily driven by video relevance, followed by a comprehensive evaluation based on popularity metrics such as views and likes. However, more detailed information about the algorithm's formulas and methodologies is unavailable due to concerns related to commercial confidentiality.

Video retrieval was conducted on a Windows 10 (Microsoft Corporation) personal computer using a newly installed Mozilla Firefox browser (version 121.0.1; Mozilla Foundation and Mozilla Corporation) in Suzhou, Jiangsu, China, within a single day (December 28, 2023) to minimize potential bias from newly uploaded content. To reduce the influence of personalized recommendation algorithms, all cookies, browsing history, and temporary internet files were cleared, and platform accounts were logged out before and between search queries, which were performed in incognito mode.

Video Selection Criteria

After conducting the searches, the top 100 videos automatically recommended based on the default overall ranking on each video platform were selected and prepared for initial screening. This decision was informed by previous literature indicating that most amateur health seekers rarely browse beyond the first 2 pages of search results [23]. Additionally, most Chinese-language video-sharing platforms limit the number of videos displayed per page to no more than 30. Specifically, Bilibili displays 30 videos per page, Haokan Video 10, Xigua Video 20, and Douyin 20. Therefore, we believe that our sample size (n=100) exceeds the number of videos typically displayed on the first 2 pages (Bilibili, n=60; Haokan Video, n=20; Xigua Video, n=40; and Douyin, n=40), which audiences are most likely to engage with, thereby ensuring representativeness. Furthermore, a sample size of 100 has been widely adopted in similar previous studies [24-26], further supporting the rationale for selecting the top 100 automatically recommended videos for subsequent filtering and analysis.

The exclusion criteria were defined as follows: (1) videos not directly related to stroke prevention; (2) duplicated videos repeatedly uploaded to the same platform; (3) videos not in Chinese (including Mandarin, Cantonese, and other dialects); and (4) commercial advertisements. In this study, 78 off-topic videos and 9 duplicate videos uploaded to the same platform were identified and excluded, resulting in a final sample of 313 eligible videos for further analysis (Figure 1). All eligible videos were produced in Mandarin Chinese, and no highly similar or fully duplicate videos were observed across different platforms.

General Information Extraction

For the included videos, general information, including URLs; authorship; number of views, likes, shares, and comments; upload date; and video length (in seconds), was collected and recorded in an Excel spreadsheet (Microsoft Corporation) by an independent researcher (RGG).

Classification of Videos

The included videos were categorized based on the identity of their producers as follows: (1) general users (eg, amateurs); (2) health professionals (eg, medical practitioners); (3) science communicators (eg, citizen science storytellers); (4) news agencies (eg, CCTV [China Central Television]); (5) medical organizations (eg, hospital); (6) for-profit organizations (eg, commercial health care–related enterprise); and (7) nonprofit organizations (eg, voluntary patient communities).

For videos classified under health professionals, a further subcategorization was conducted as follows: (1) doctors specializing in neurology within modern evidence-based medicine; (2) doctors specializing in other areas of modern evidence-based medicine; (3) doctors of traditional Chinese medicine (TCM); and (4) other health-related professionals, further specified according to their specialty. Detailed definitions of the authorship categories are provided in Table S1 in Multimedia Appendix 1.

Video Evaluation Framework

Quality and Reliability Assessment

After completing the video retrieval, exclusion, and classification, 2 separate questionnaires were used to quantitatively assess the overall quality and reliability of the included online videos on stroke prevention.

The DISCERN instrument, first introduced in 1999 to evaluate the quality of online information on treatment choices [27], has since been widely validated and applied to assess health-related content on video-sharing platforms [28,29]. In 2012, Singh et al [30] developed a modified version of DISCERN, streamlining the original 16-question format into a 5-question version that focuses on clarity, reliability, bias/balance, provision of additional information sources, and acknowledgment of areas of uncertainty. This modified version has also been extensively tested and is commonly used in previous studies [31-35]. Therefore, in this study, we used the modified DISCERN instrument to assess the reliability of video content based on its 5 items (Table 2). The total score of the modified DISCERN tool ranges from 0 to 5, with higher scores indicating greater reliability (from unreliable to reliable). Furthermore, the GQS, a commonly used 5-point scale ranging from 1 (poor quality) to 5 (excellent quality) for evaluating health-related content on the internet [25,36,37], was also applied to assess the overall quality of the included videos (Table 3).

Table . Modified DISCERN questionnaire (1 point for every yes and 0 points for no) items and their descriptions.

Item	Description
1	Are the aims clear and achieved?
2	Are reliable sources of information used?
3	Is the information presented balanced and unbiased?
4	Are additional sources of information listed for patient reference?
5	Are areas of uncertainty mentioned?

Table . Global Quality Scale grades and their descriptions.

Grade	Description
1	Poor quality, poor flow, most information missing; not helpful for patients.
2	Generally poor, some information given; limited use for patients.
3	Moderate quality, some information is adequately discussed, but important topics are missing; somewhat useful to patients.
4	Good quality and flow, most relevant information is covered; useful for patients.
5	Excellent quality and flow; very useful for patients.

Two qualified neurologists (HYD and YHX), both with sufficient medical education and clinical experience, were assigned to independently assess the included online videos using the modified DISCERN and GQS tools. Before formal scoring, both raters thoroughly reviewed and familiarized themselves with the questionnaires to minimize potential biases caused by any misunderstanding of the scoring instruments.

Moreover, the Cohen κ test was used to assess interrater agreement. A value greater than 0.8 was considered indicative of excellent consistency; a value between 0.8 and 0.6 represented substantial consistency; a value between 0.6 and 0.4 indicated moderate consistency; and a value below 0.4 was considered poor consistency [38]. Disagreements between the 2 reviewers were resolved through discussion; if a consensus could not be reached, a senior researcher (YJC) was appointed to make the final decision.

XSL•FO
RenderX

Video Content Evaluation

With regard to the video content related to stroke prevention, 3 key aspects were considered, as outlined below: (1) Which stage of stroke prevention was mentioned (primary, secondary, or both)? (2) What specific preventive measures were recommended (including both pharmacological and nonpharmacological approaches)? (3) What were the frequency and proportion of specific stroke prevention measures recommended in the videos?

As for the rationale behind using this 3-item combined evaluation strategy: Identifying the stage of prevention helps determine whether a video emphasizes preventing the initial onset of stroke or preventing recurrence, an area often overlooked in public education. Examining the specific preventive strategies provides insight into whether the content offers accurate and actionable guidance aligned with current clinical guidelines. Lastly, quantifying the frequency and distribution of these strategies allows for an assessment of the consistency and emphasis of public health messaging across different videos and platforms. Together, these 3 items offer a structured lens through which to assess both the breadth and clinical relevance of video content, aligning with the overall goal of evaluating the educational quality and reliability of Chinese-language videos on stroke prevention.

This procedure was performed by another independent reviewer (CCG), and any uncertainties were resolved through discussion with the research team.

Statistical Analysis

In this study, the Shapiro-Wilk test was used to assess the normality of the quantitative data extracted from the included videos. For nonnormally distributed data, the median and IQR were used for descriptive analysis, whereas for normally distributed data, the mean and SD were reported. Categorical data were presented as absolute numbers and percentages.

Comparisons between 2 groups were performed using the nonparametric Mann-Whitney *U* test, while comparisons among 3 or more groups were conducted using the Kruskal-Wallis *H* test. The Spearman correlation coefficient was then used to examine associations between video variables and quality and reliability scores. For interpretation, a correlation coefficient less than 0.10 was considered negligible; between 0.10 and 0.39, weak; between 0.40 and 0.69, moderate; between 0.70 and 0.89, strong; and greater than 0.90, very strong [39]. Finally, a linear regression model was applied to explore potential temporal trends in the quality and reliability of stroke prevention–related videos over the upload period. A *P* value of <.05 was considered statistically significant. All analyses were performed with the GraphPad Prism software (version 9.5.1; GraphPad Software, Inc).

Ethical Considerations

This study did not involve human participants or experimental animals; therefore, ethics approval and consent to participate were not applicable. Our study involved the analysis of publicly available data or the use of secondary data that do not contain any personal identifiers, thus ensuring the anonymity and confidentiality of the individuals concerned. Compliance with ethical standards was maintained throughout the research process.

Results

Overview

As shown in Figure 1, after the search and screening process, a total of 313 eligible online videos on stroke prevention education were included for further analysis. Of these, 68 were from Bilibili, 74 from Douyin (the Chinese counterpart of TikTok), 86 from Haokan Video, and 85 from Xigua Video.

Overall, as shown in Table 4, the median values among the included videos were as follows: video length, 137 seconds; views, 779; likes, 18; shares, 67; and comments, 1. Regarding the year of video upload, the number of uploaded videos has steadily increased over time, with the majority uploaded in 2023, accounting for 106 out of 313 (33.9%) total videos uploaded. When analyzed by video authorship, health professionals, including doctors specializing in neurology and other fields of modern medicine, doctors of TCM, and pharmacists, collectively created and uploaded 113 stroke prevention–related videos (n=113, 36.1%), followed by news agencies (n=95, 30.4%) and general users (n=40, 12.8%). More detailed descriptive results by video platforms are presented in Table 4.

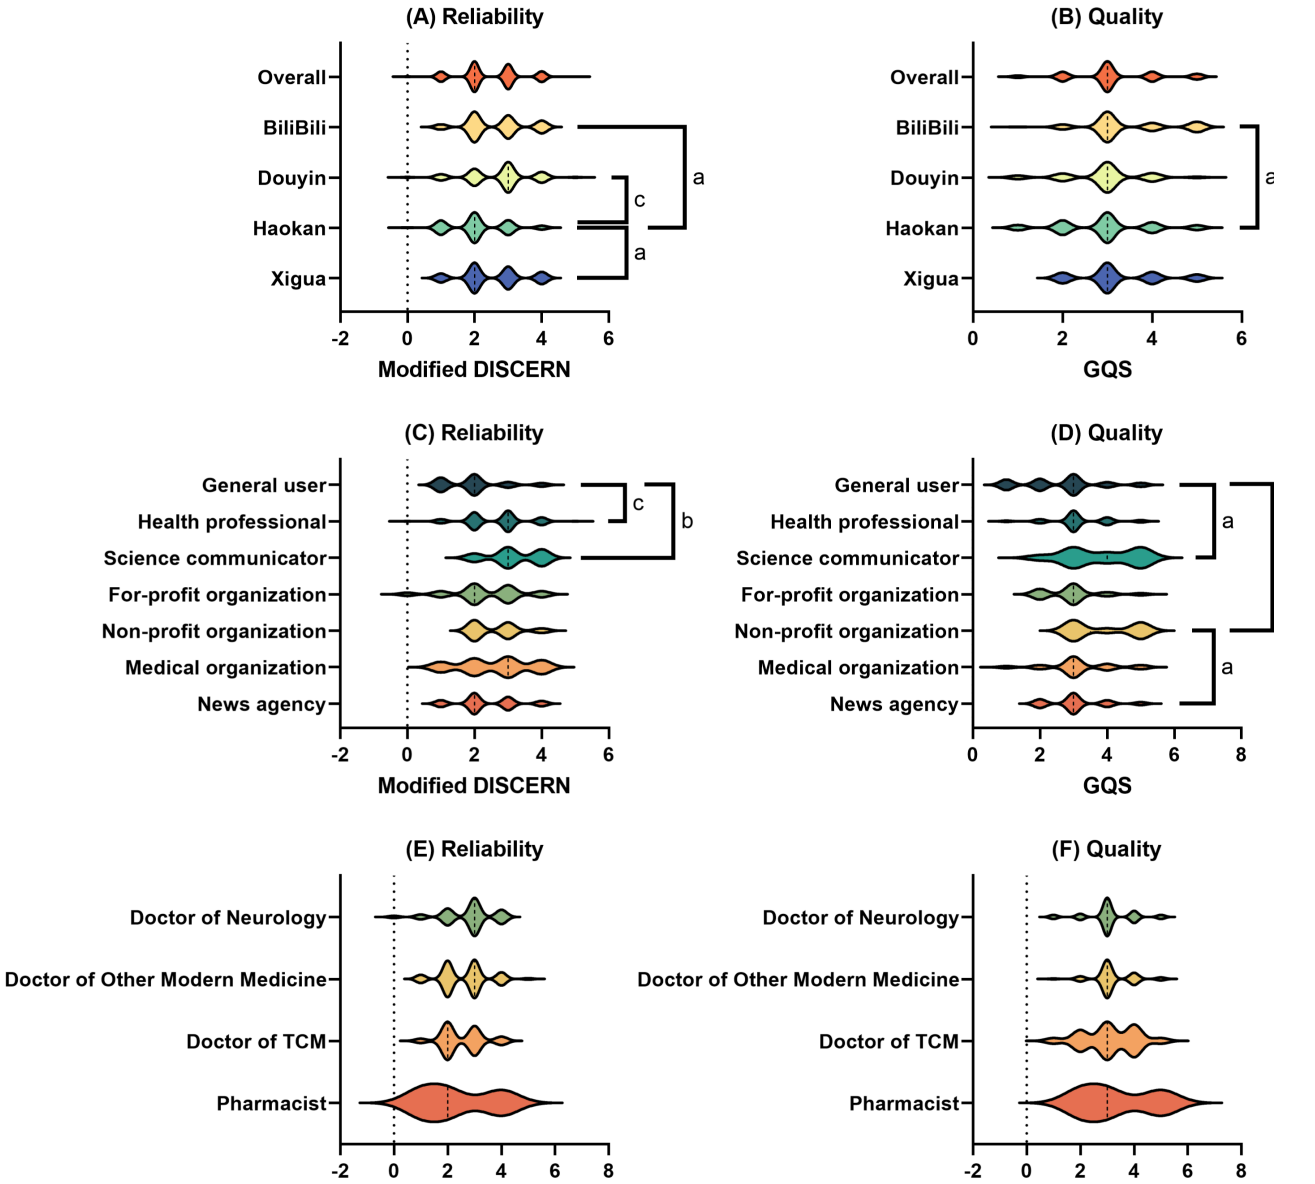
[a]The number of views was not available for the Douyin platform.

[b]The number of shares was not available for the Haokan platform.

[c]The number of shares was not available for the Xigua platform.

With regard to the overall quality and reliability of the included online videos, the kappa coefficients for the modified DISCERN and GQS scores, as assessed by 2 independent raters, were 0.71 and 0.73, respectively, indicating substantial interrater agreement. The observed discrepancies were primarily due to 1 rater slightly overestimating the quality and reliability of certain stroke prevention–related videos. However, most of these minor disagreements were resolved through discussion between the 2 raters. In cases where disagreement persisted, a senior researcher was assigned to make the final decision. Taken together, with the median scores for the modified DISCERN and GQS being 2 and 3, respectively, our results suggest that the included videos exhibited relatively poor reliability but moderate quality.

Video Upload Timeline



The distribution of video uploads over time revealed a clear upward trend. As shown in Table 4, the number of stroke prevention–related videos increased steadily each year. Only a small proportion of videos were uploaded before 2020, with a marked rise beginning in 2021. Notably, the highest number of videos (n=106, 33.9%) was uploaded in 2023 alone, suggesting growing public and institutional engagement with stroke-related health education on video platforms in recent years. This increase may reflect heightened awareness of cerebrovascular disease prevention, evolving content production practices, or rising user engagement with online platforms across China. These temporal patterns underscore the relevance and urgency of evaluating video-based health information, as both the volume and impact of such content continue to grow.

Quality and Reliability by Video Platform

When examined by specific online video platforms, as shown in Figure 2A and B, our results suggest that videos from Douyin (median modified DISCERN score of 3) exhibited higher median reliability score compared with those from other platforms (median modified DISCERN scores of 2.5, 2, and 2 for Bilibili, Haokan Video, and Xigua Video, respectively). However, this difference was statistically significant only between Douyin and Haokan Video (P<.001). Meanwhile, in terms of video quality, the median GQS scores were highly consistent across the 4 video platforms (GQS=3 for all 4 platforms). A statistically significant difference was observed only between Bilibili and Haokan Video (P=.03).

XSL•FO
RenderX

Figure 2. The modified DISCERN and Global Quality Scale (GQS) scores by (A, B) specific video platform, (C, D) video creators, and (E, F) health care professionals. [a]*P*<.05, [b]*P*<.01, [c]*P*<.001. TCM: traditional Chinese medicine.

Quality and Reliability by Video Authorship

When analyzed by specific video creator categories, as shown in Figure 2C and D, videos produced by health care professionals (median modified DISCERN score of 3) and science communicators (median modified DISCERN score of 3) demonstrated greater reliability compared with those created by amateur individual users (median modified DISCERN score of 2). However, no statistically significant difference was observed among videos created by different organizational authors (*P*>.99 in all cases). In terms of video quality, the findings were consistent with those for video reliability. Stroke prevention–related videos created by science communicators received higher GQS scores (median GQS score of 4) than those by amateur individual users (median GQS score of 3). No significant difference was observed between videos created by health care professionals and those by amateur users (*P*=.06). Among organizational video creators, videos from nonprofit organizations (median GQS score of 3.5) demonstrated higher quality compared with those from amateur users and news agencies (median GQS score of 3 for both cases).

When the health care professional authorship category was further subdivided (Figure 2E and F), no statistically significant differences were found among videos produced by neurologists (*P*>.99), doctors from other fields of modern medicine (*P*>.99), doctors of TCM (*P*>.99), and pharmacists (*P*>.99), regardless of whether the assessment was based on reliability or quality. However, despite the lack of statistical significance (*P*>.99), videos created by doctors specializing in modern medicine received higher reliability scores than those produced by TCM doctors (median modified DISCERN scores of 3 for both neurologists and other modern medical specialists vs 2 for TCM doctors). Interestingly, pharmacists, though contributing a relatively small proportion of the videos, produced content with moderate quality (median GQS score of 3), possibly reflecting their specialized knowledge in pharmacological prevention

XSL•FO
RenderX

strategies, such as the use of antiplatelet agents for stroke risk reduction.

These findings suggest that professional background may influence the rigor of content, even if the differences are not substantial, and underscore the potential value of encouraging more contributions from neurologists and other clinical specialists in stroke-related video creation.

Video Content Analysis

Regarding the stroke prevention strategies recommended in the included online videos, the vast majority focused on primary prevention (n=262), targeting the first onset of stroke. By contrast, relatively few addressed secondary prevention aimed at preventing stroke recurrence (n=28), and only a small number of videos covered both primary and secondary prevention simultaneously (n=23).

To be more specific, among primary stroke prevention measures, the most frequently mentioned strategy was controlling abnormal blood pressure (158/313, 50.5%), followed by adopting healthy dietary habits (145/313, 46.3%) and engaging in physical activity (144/313, 46.0%). These lifestyle-oriented recommendations reflect prevailing public health messaging trends and align with international stroke prevention guidelines. By contrast, for secondary prevention, the most frequently recommended measure was also managing abnormal blood pressure (24/313, 7.7%), followed by controlling abnormal blood glucose (21/313, 6.7%), regulating abnormal blood lipid levels (21/313, 6.7%), and using oral antiplatelet agents (21/313, 6.7%). This distribution suggests that, where addressed, secondary prevention videos tended to emphasize pharmacological and laboratory-monitored interventions rather than lifestyle-based recommendations.

Collectively, these findings suggest that while primary prevention dominates the landscape of online stroke-related education in China, a considerable gap exists in public-facing content addressing secondary prevention. Enhancing the visibility and clarity of such content, particularly among stroke survivors, may represent a valuable opportunity for public health intervention.

Correlation of Video General Information With Quality and Reliability

As shown in Table 5, significant correlations were observed among several general video information metrics. In particular, the number of views was positively associated with video length, number of likes, number of shares, and number of comments (r=0.142, P=.03; r=0.838, P<.001; r=0.897, P<.001; and r=0.593, P<.001, respectively). Similarly, videos that received more likes were more likely to have higher numbers of shares and comments (r=0.900, P<.001 and r=0.816, P<.001, respectively).

Table . The Spearman correlation coefficient between general video information and video quality and reliability.

Correlation	Video Length (s)	Views	Likes	Comments	Shares	Modified DISCERN score	Global Quality Scale score
Video Length (seconds)	1.000	—[a]	—	—	—	—	—
Views (n)	0.142[b]	1.000	—	—	—	—	—
Likes (n)	−0.060	0.838[b]	1.000	—	—	—	—
Comments (n)	−0.045	0.593[b]	0.816[b]	1.000	—	—	—
Shares (n)	−0.017	0.897[b]	0.900[b]	0.826[b]	1.000	—	—
Modified DISCERN scores	0.151[b]	−0.105	0.027	0.137[b]	0.019	1.000	—
Global Quality Scale score	0.441[b]	−0.042	−0.077	−0.017	−0.110	0.559[b]	1.000

[a]Not applicable.

[b]Statistical significance (P<.05).

Nevertheless, when considering video quality and reliability, video length was found to be positively correlated with both the modified DISCERN and GQS scores (r=0.151, P=.007 and r=0.441, P<.001, respectively). Additionally, a greater number of comments was associated with higher video reliability, although this correlation was relatively weak (r=0.137, P=.01).

Temporal Trend in Video Quality and Reliability

According to Figure S1 in Multimedia Appendix 1, an analysis of video upload time revealed a slight but statistically significant positive correlation between more recent upload dates and both video quality (P=.002) and reliability (P=.01). Specifically, Pearson correlation coefficients indicated that videos uploaded more recently tended to have higher GQS scores (r=0.113, P=.002) and higher modified DISCERN scores (r=0.086, P=.01). Although the strength of these associations was relatively weak, the findings suggest a gradual improvement in the overall quality and reliability of stroke-related video content over time. This trend may reflect growing awareness among content creators regarding evidence-based health communication, as well as improved platform policies aimed at enhancing the accuracy of health information.

Discussion

Principal Findings

In this study, by searching and screening online videos related to stroke prevention across 4 popular Chinese-language video platforms, we systematically described and analyzed the general characteristics, as well as the overall quality and reliability, of the included health-related online videos. To the best of our knowledge, this may be one of the first studies to specifically evaluate and report on the quality and reliability of Chinese-language online video platforms as information sources for stroke prevention education in Mainland China. We hope that our findings will provide valuable data for real-world policy makers and medical practitioners, ultimately contributing to improved stroke prevention and management efforts in the future.

Overall, using the modified DISCERN and GQS instruments, the included online videos related to stroke prevention were evaluated as relatively unreliable and of moderate quality. This suggests that, although video creators may offer some useful advice on primary and secondary stroke prevention measures, they often fail to provide supporting references and frequently lack fairness and objectivity in presenting information. These findings are consistent with previous research in other medical domains, which has similarly shown that health-related content on new media, particularly online video-sharing platforms, is often unsatisfactory and, at times, misleading [40-43]. This phenomenon may be largely attributed to the competition for audience attention in the digital marketplace, where accurate scientific information, often complex and less engaging for the general public, is easily overshadowed by sensationalized or simplified claims [44]. Consequently, entertainment-oriented online platforms are more likely to recommend light, engaging content over scientifically rigorous materials, which may be more difficult for general audiences to understand. Nevertheless, a growing number of stroke-related educational videos are being created and uploaded each year, suggesting that stroke prevention is becoming an increasingly visible topic on Chinese social media, particularly on video-sharing platforms. Notably, a positive temporal trend was observed in the quality and reliability of stroke-related videos uploaded between 2017 and 2023. We speculate that this improvement may be driven by increased participation from health care professionals in content creation, thereby directly contributing to the enhanced quality of stroke prevention information available online.

When analyzed by specific video platforms, videos from Douyin appeared to be more favorable, exhibiting higher content quality and reliability compared with those from the other 3 platforms, although statistical significance was not consistently observed. This finding may be explained by the fact that approximately 81% of eligible videos on Douyin were created and uploaded by qualified health care professionals, who generally receive more comprehensive and systematic evidence-based medical education and training than general users. Therefore, this phenomenon is relatively understandable. However, when the data for health care professionals were further stratified into more specific subgroups, videos created by doctors specializing in modern medicine—regardless of their field—tended to be more reliable than those produced by doctors of TCM, despite the absence of statistically significant differences.

Unfortunately, alongside the potentially beneficial health-related recommendations found in stroke prevention videos, concerns have also been raised about the prevalence of misinformation in the included study videos. Notably, some general individual users without a medical education background may share personal opinions in their videos that lack solid scientific evidence. For example, one video created by amateurs claimed that “regularly receiving intravenous injections can prevent stroke onset because it may help clear blood vessels.” This statement has been identified as a widely circulated misconception among the Chinese population, particularly among older adults. Additionally, some video creators were observed to use emotionally charged and sensationalized titles and content, rather than objective and evidence-based information, in an effort to attract public attention and maximize viewership. However, this approach may lead to severe misunderstandings that could potentially jeopardize public health at the community level. Furthermore, the risk of misinformation is not limited to nonprofessionals, as certain content produced by health care professionals also warrants scrutiny. Specifically, current stroke prevention recommendations and suggestions from TCM doctors are highly heterogeneous, with some approaches not yet completely validated by formal clinical trials and largely based on empirical knowledge. For instance, some TCM practitioners propose that massage on specific body points (commonly referred to as “acupoints”) may help prevent cerebral stroke. While this perspective is rooted in traditional practice, there is currently insufficient evidence from randomized controlled trials to substantiate its efficacy. Nevertheless, despite TCM’s historically experience-driven approach, it remains an integral component of China’s health care system and continues to serve as a complementary and alternative option in stroke prevention and management. In recent decades, TCM practitioners have made concerted efforts to integrate traditional practices with modern scientific research, contributing to its ongoing development and potential role in future stroke care [45].

To effectively address these issues, several targeted countermeasures can be implemented to enhance the quality and reliability of health-related online videos and information [46-48]. First and foremost, the review process for medical information videos uploaded to online platforms should be reinforced and supervised in collaboration with qualified medical professionals. Additionally, establishing and strengthening an online monitoring and correction system could help limit the spread of misinformation and reduce its long-term impact. Finally, general social media users should be encouraged to share controversial health information more selectively and cautiously, in order to curb the dissemination of false content and restrict accounts that produce or promote it.

Recently, Chinese governmental departments and relevant enterprises have begun taking active measures to combat the widespread dissemination of health-related misinformation online. For example, in collaboration with the Ministry of Industry and Information Technology, the Chinese National

XSL•FO
RenderX

Health Commission issued a policy on May 27, 2024, aimed at urgently strengthening the regulation of health-related webcasting, video content, and promotional activities on digital platforms. Simultaneously, ByteDance (TikTok's parent company) launched a centralized governance initiative in 2024 focused on identifying and removing poor-quality or even fraudulent sources of medical information. Beyond China, the World Health Organization (WHO) has proposed several countermeasures to limit online misinformation [49]. These include awareness campaigns targeting patients and health care professionals, the promotion of platforms that provide evidence-based data, the integration of scientific evidence into health-related content in mass media, and efforts to improve media and health literacy. Additionally, the WHO encouraged the active involvement of experts and health care professionals in debunking misinformation and guiding internet users toward credible, evidence-based information sources. However, the persistence of misinformation in the digital space, particularly in health care, continues to pose a significant threat to public well-being worldwide. This ongoing challenge underscores the urgent need for stronger guidelines and innovative strategies to mitigate its impact effectively.

In addition to evaluating the quality and characteristics of stroke-related videos, it is important to consider the platform-specific policies that may influence the dissemination of health content. Major Chinese video-sharing platforms, such as Douyin, have publicly issued guidelines encouraging the distribution of accurate and authoritative health information. For instance, these platforms typically require health-related content creators to verify their professional credentials and may implement content moderation mechanisms to flag or remove misleading medical information. However, the enforcement and transparency of these policies vary across platforms, and the extent to which they affect the quality and reach of health-related videos remains largely understudied. Future research could benefit from a more systematic analysis of how platform-level governance affects the credibility and visibility of online health communication.

Limitations

Despite these findings, several limitations of this study should be acknowledged. First and most importantly, our research team retrieved and analyzed only Chinese-language videos targeting Chinese audiences, using a limited set of search keywords. Videos in other languages, such as English, Japanese, and Korean, were not included, indicating a need for broader investigation in future research. Second, although measures were taken to minimize potential bias introduced by platform algorithms during the initial video search, we cannot fully exclude the possibility that our results were influenced by the artificial intelligence algorithms used by commercial video platforms. To be more specific, video search engines tend to prioritize and recommend content with higher engagement metrics. Although we logged out of our accounts, deleted temporary files and cookies, and conducted searches using a newly installed internet browser, the inherent nature of these automatic algorithms amplifies disparities between videos—allowing popular content to gain increasing visibility, while less popular videos receive minimal exposure. Consequently, this unavoidable limitation may have influenced the collection of general video-related metrics, particularly likes and shares. Third, this study was based on a limited sample size (from only 4 Chinese domestic video platforms). Therefore, further research involving a larger number of videos and platforms with broader representativeness is urgently needed. Fourth, data collection was conducted on a single day, which may not fully capture the dynamic and evolving nature of content rankings on video platforms. Videos that consistently maintain high visibility over time might have been overlooked, and our findings may therefore represent only a snapshot of what users were most likely to encounter at that specific moment. Future studies could incorporate longitudinal sampling strategies to account for temporal variations in content prominence. Finally, as a cross-sectional study using a relatively subjective evaluation strategy, this study primarily focused on a descriptive assessment of the current state of online video-based patient education in Mainland China. Therefore, future prospective studies are warranted to evaluate the real-world effectiveness of physician-created and peer-reviewed video materials for patient education.

Conclusion

This study examined the overall quality and reliability of Chinese-language videos related to public patient education on stroke prevention. The findings suggest that the quality and reliability of health-related videos, as a source of information for stroke management, remain relatively unsatisfactory and should be approached with caution by Chinese audiences. Therefore, targeted countermeasures, such as reinforcing the video content review process, establishing online correction mechanisms, and encouraging users to selectively and carefully share controversial information, are urgently needed to enhance the credibility and impact of stroke-related educational content in the future.

Abstract

Background: Prevalence and spread of misinformation are a concern for the exacerbation of vaccine hesitancy and a resulting reduction in vaccine intent. However, few studies have focused on how vaccine misinformation diffuses online, who is responsible for the diffusion, and the mechanisms by which that happens. In addition, researchers have rarely investigated this in non-Western contexts particularly vulnerable to misinformation.

Objective: This study aims to identify COVID-19 vaccine misinformation, map its diffusion, and identify the effect of echo chamber users on misinformation diffusion on a Taiwanese online forum.

Methods: The study uses data from a popular forum in Taiwan called PTT. A crawler scraped all threads on the most popular subforum from January 2021 until December 2022. Vaccine-related threads were identified through keyword searching (n=5818). Types of misinformation, including misleading, disinformation, conspiracy, propaganda, and fabricated content, were coded by 2 researchers. Polarity was proposed as a proxy for measuring an individual's level of involvement in the echo chamber, one of the mechanisms responsible for the viral misinformation on social media. Factors related to information diffusion, including misinformation type and polarity, were then assessed with negative binomial regression.

Results: Of 5818 threads, 3830 (65.8%) were identified as true information, and 1601 (27.5%) contained misinformation, yielding 5431 boards for analysis. Misinformation content did not vary much from other contexts. Propaganda-related information was most likely to be reposted (relative risk: 2.07; $P<.001$) when comparing to true information. However, the more polarized a user was, the less likely his or her content was to be reposted (relative risk: 0.22; $P<.001$). By removing the nodes with a high level of indegree, outdegree, and betweenness centrality, we found that the core network and the entire network demonstrated a decreasing trend in average polarity score, which showed that influential users contributed to the polarization in misinformation consumption.

Conclusions: Although the forum exhibits a resilience to echo chambering, active users and brokers contribute significantly to the polarization of the community, particularly through propaganda-style misinformation. This popularity of propaganda-style misinformation may be linked to the political nature of the forum, where public opinion follows "elite cues" on issues, as observed in the United States. The work in this study corroborates this finding and contributes a data point in a non-Western context. To manage the echo chambering of misinformation, more effort can be put into moderating these users to prevent polarization and the spread of misinformation to prevent growing vaccine hesitancy.

KEYWORDS

misinformation; vaccine; online community; influencer; echo chamber; Taiwan

Introduction

Background

As individuals increasingly turn to social media as a primary source of information, the prevalence and spread of unverified or misinformed scientific claims is concerning [1]. Social media users gravitate toward information that validates their belief systems, forming echo chambers that validate their shared narrative [2]. These echo chambers can be the launching pads for misinformation that goes viral [3]. Worse, they can influence opinions on issues of public concern, such as vaccination [4].

XSL•FO
RenderX

As early as 2001, studies identified the rise of vaccine hesitancy online [5,6] and cataloged the techniques in antivaccination misinformation transmission [7,8]. These studies paralleled the early days of the World Wide Web and focused solely on analyzing web pages. An early study by Zimmerman et al [6] found that misrepresentation (twisting of content) was a method for conveying vaccine misinformation. Kata [8] elaborated on misrepresentation in her study in 2010 on childhood vaccination. In her study, misinformation, a sort of misrepresentation, was a main antivaccination theme that arose in classification. Under the misinformation umbrella, she found that using outdated sources; misrepresenting facts; self-referencing to "experts"; not referencing statistics or citations; and making unsupported statements were all ways of passing misinformation. The use of negative tones is also a method of strengthening antivaccination methods [9].

As misinformation became more prevalent on social media, exacerbated by the terming of "fake news" and a global pandemic, more research was conducted on clarifying the definition of misinformation and classifying the different kinds of misinformation. The term "misinformation" is often used interchangeably with related concepts such as spam, rumors, fake news, and disinformation. In this study, we use "misinformation" as an umbrella term to encompass all false or inaccurate information disseminated through social media. Under these umbrellas, there are different types of misinformation. Some information can be fabricated content, while some can be manipulated to be clickbait. Some can be satire or parody being passed off as true, and some can be propaganda [10]. Information can be passed off as true via sponsors and be partially true or totally false. New modes of producing synthetic media through artificial intelligence such as "deep fakes" distort reality by passing as true. Although there is nuance between the different types of misinformation, all types are distinct from true information, which is not deliberately fabricated with malicious intent and does not contain false (scientific) information.

There are several studies on classifying types of vaccine misinformation. Wu et al [11], in their study on general misinformation in social media, tentatively organized misinformation into nonexclusive categories such as unintentionally and intentionally spread misinformation, urban legend, fake news, unverified information, rumor, crowdturfing, spam, and trolling. Zhao et al*'s* [12] study does not deviate far from this. They identified that misinformation could include conspiracies; concerns about vaccine safety and efficacy; a flat rejection of all vaccines; morality (including religion and human experimenting); and a violation of civil liberties. Classification studies also identified new modes of transmission. Basch et al [13] studied the types of misinformation on TikTok, a medium mixing audiovisual and textual cues, and found that parodying or the overemphasis of false consequences of available vaccines were all methods of strengthening an antivaccination narrative.

In addition to modes of transmission and classification, some studies have focused on linking misinformation to vaccination intent, although these are sparse. One study used a questionnaire to identify that COVID-19 vaccine hesitancy mediated the relationship between vaccine knowledge and vaccination intention, with misinformation on vaccines being associated with higher vaccine hesitancy. The same study also claimed that most respondents were exposed to COVID-19 misinformation [14]. Another study conducted a randomized controlled trial, finding that exposure to recent misinformation induced a decline in intent of vaccination. This is especially true when the misinformation is transmitted as misrepresenting facts of a scientific nature [15].

In the studies on vaccine misinformation, there are unexplored avenues. Few studies have examined how vaccine misinformation diffuses online, both in time and in quantity. Diffusion is a communication process whereby information is communicated over time "among the members of a social system" [16]. Often, this process is measured in terms of depth, breadth, and speed [17,18]. Diffusion depth refers to the length of the longest transmission chain, breadth refers to the capacity to generate offspring posts, and speed refers to the efficiency of the information diffusion process [19]. Understanding the diffusion process between true information and misinformation is important because, should approaches such as psychological inoculation [20] or other vaccination community strategies work [21,22], understanding the scale of spread and when to intervene diminishes the spread.

In addition, no studies have studied key users' roles in spreading vaccine misinformation. This can be broken down into 2 symbiotic perspectives. One perspective is looking at how individuals' engagements online may be polarizing or divisive. Previous research on polarity focused on this mostly in politics, using different metrics of measurement for polarity. One study assessed political polarization using interactional, positional, and affective polarity across various platforms to find that polarization is platform dependent [23]. Another study looked at affective polarization against the feminist cause following protests [24]. In the vaccination literature, polarity mostly focuses on differences in vaccine sentiment [4,25,26], aligning it with affective polarization. However, there are a paucity of studies analyzing polarity in engagement with misinformation. This is important because the deliberate exclusion of true perspectives on vaccination may affect the downstream intention to vaccinate. Echo chambers that form around misinformation are thus one avenue worth exploring. Previous research has found that echo chambers are related closely to misinformation diffusion [27] and that misinformation disseminated by echo chambers spread more virally than misinformation not distributed by them [28].

The second perspective is identifying who the key users are in this process. One can see how the polarity in the endorsement of misinformation can be exponentially more problematic when the users doing the exclusion are both laypeople [29] and central in the network. Two studies found that information diffused by "brokers"—those who have high betweenness centrality—affects the final size of information cascades [30,31]. For health information, the diffusion size of posts by the US Centers for Disease Control and Prevention (CDC) were related to broker involvement [32]. More work can thus be done on understanding how key users aid in spreading vaccine misinformation through the deliberate exclusion of "true news," thereby enhancing its dissemination.

XSL•FO
RenderX

The consequence of having these key users spread information lies in the fact that individual beliefs are shaped by their immediate social network, both online and offline [33]. These worlds feed back to each other, entrenching belief. Scholars have found that dissemination of misinformation is driven by social reinforcement in an individual's digital circles [34]. If a person's network consists of mostly rumormongers, that person in turn likely propagates the same misinformation. This propagation often spills into the offline space, influencing judgment through reinforcing the legitimacy of the information online [35], eventually creating fissures along sociodemographic lines, further polarizing the offline world [36]. Should this process occur for vaccine information, it would exacerbate the issue of vaccine hesitancy and have negative implications for vaccination. Few studies have examined the upstream part of this process, including in non-Western contexts [36]. This study focuses on vaccine misinformation on a local forum in Taiwan (PTT) from 3 aspects: identifying the types of misinformation, describing how it diffuses relative to regular news, and assessing how influential users fall into chambers of misinformation, affecting its spread.

Research Questions

This study uses the same PTT data to address the following questions about misinformation. First, we will determine what types of misinformation are present in a Taiwanese online community. This identification and categorization archives how misinformation topics differ to other contexts considering the sociopolitical context of Taiwan. Second, the study will determine how misinformation cascades differ from true information by dichotomizing the topics, comparing their breadth [19]. Finally, we will assess to what extent the echo chamber phenomenon exists in the diffusion of misinformation and how influential users, as a proxy for understanding key spreaders of misinformation, affect the echo chamber in the network. The findings of this study can inform how Taiwan can combat growing misinformation in its diverse online ecology.

Methods

Data Procurement

PTT is a terminal-based bulletin board system developed in Taiwan in 1995. Functioning like an internet forum, PTT is often termed Taiwan's "Reddit" and is one of the most active forums in Taiwan. From July 2022 to July 2023, the average number of users per day was 56,000 [37]. The web-based version of PTT is structured into different boards, which are equivalent to thematic groups, on a forum. Within each board, threads or topics can be started. On each thread, the poster's metadata such as the username, time of post, and IP address are available for scraping. In addition, within the threads there is a comment section for which the corresponding metadata is also available.

The data for this study were collected from the "Gossiping" board on PTT using a web scraper developed in Python to extract HTML data. The scraping targeted posts made between January 2021 and December 2022. We filtered the dataset using the Chinese term for "vaccine" to ensure we captured vaccine-related threads. The language of all collected data was Mandarin Chinese, the primary language used on PTT. The "Gossiping" board was specifically chosen due to its high activity levels and its reputation for users engaging in a wide range of discussions, including those related to public health, politics, and societal issues. This board is particularly active during times of political or social crises, making it a rich source for analyzing vaccine misinformation during the COVID-19 pandemic. Other thematic boards were excluded to maintain focus on a general-purpose discussion forum where misinformation may more organically spread across a wider audience. In total, 5818 boards were pulled.

Identifying Misinformation

The coding process for classifying vaccine misinformation followed an established framework based on existing literature. We used a broad classification scheme (Table 1) derived from studies on misinformation in digital spaces, which categorize misinformation into types such as conspiracies, fabricated content, fake news, and political propaganda. The classification of posts into misinformation categories was conducted in Mandarin by 2 trained coders, who worked independently to classify an initial sample of 500 posts. The initial codebook was developed using an inductive coding approach, where new categories emerged from the data during this pilot phase. The coders reached a high level of intercoder reliability, with a Cohen κ of 0.91, indicating strong agreement. Discrepancies were resolved through discussion, and the finalized codebook was used to classify the remaining 5318 posts.

Table . Labeling scheme for true information and false information.

Category and label	Classification criteria
True information	
Factual news	Reporting of news events or facts without interpretation or analysis
Scientifically accurate analytical content	Interpreting or analyzing facts or data to provide deeper understanding
Misinformation	
Misleading information	False or inaccurate information, regardless of intention
Disinformation	Deliberately created and shared with the intent to mislead or deceive
Propaganda	Biased or misleading information used to promote a political cause or push a certain point of view
Fabricated content	Entirely false content designed to deceive and mislead (create a fake news source, fake quotes, or nonexistent events)
Conspiracy	Belief or explanation that something is a result of a secret plot by a group or organization
Mixed misinformation	Two or more misinformation categories
Religious beliefs	Any discussion of religion in relation to vaccination
Unrelated	Boards containing "vaccine" keyword but unrelated to vaccine information or misinformation

Any disagreements among coders were resolved through discussion among themselves. The coders informed the principal investigator of these discrepancies, who further approved or reassessed their decision, informing the coders. As a standard reference, we consolidated a library of misinformation on COVID-19 vaccines in Taiwan from three fact-checking organizations in Taiwan: MyGoPen [38], Cofacts [39], and Taiwan FactCheck Center [40]. These organizations, led by civil society movements combatting misinformation, consolidated potentially misinformative news on a variety of topics, including those related to COVID-19. Boards related to the COVID-19 vaccine were filtered by using "vaccine" as a keyword in Chinese. In the event of disagreements on classification, the vaccine-related misinformation on these sites was used as a final check. Following the initial calibration, the remaining 5318 boards were split into 2 datasets (n=2659) and independently coded. Any questions or concerns were brought up to all coders and the principal investigator; the final classification was determined by a majority vote or mutual agreement. For comparing diffusion of misinformation and users' polarized engagement with misinformation, the categories in Table 1 are further collapsed into "true" and "false" information. Posts unrelated to vaccines or involving purely religious content were excluded from the final analysis. Thematic examples of excluded posts include those focused on general prayer requests, religious teachings not tied to vaccination, or unrelated social and political discussions. For example, posts discussing the afterlife or religious rituals were categorized as unrelated, as they did not directly engage with the vaccine misinformation discourse.

For subsequent analyses, we wanted to remove users who occasionally shared misinformation and focus on users who shared misinformation frequently (ie, we distilled a "core network" by extracting users with over 5 posts; n≥5, n=number of posts). This is also consistent with previous studies that used multiple filtering techniques to remove randomness in a large network [41,42]. To justify the choice of cutoff, robustness tests were conducted, as shown in Multimedia Appendix 1. In short, different threshold values (from 1 to 10) and the average polarity scores of the selected core network were calculated to see any significant changes. Although the average polarity increased as the cutoff increased, the trend of decreasing polarity by cutting out key users was the same across all values. To balance between cutting off too many or too few nodes for a forum, the choice of n≥5 was made.

Diffusion of Misinformation

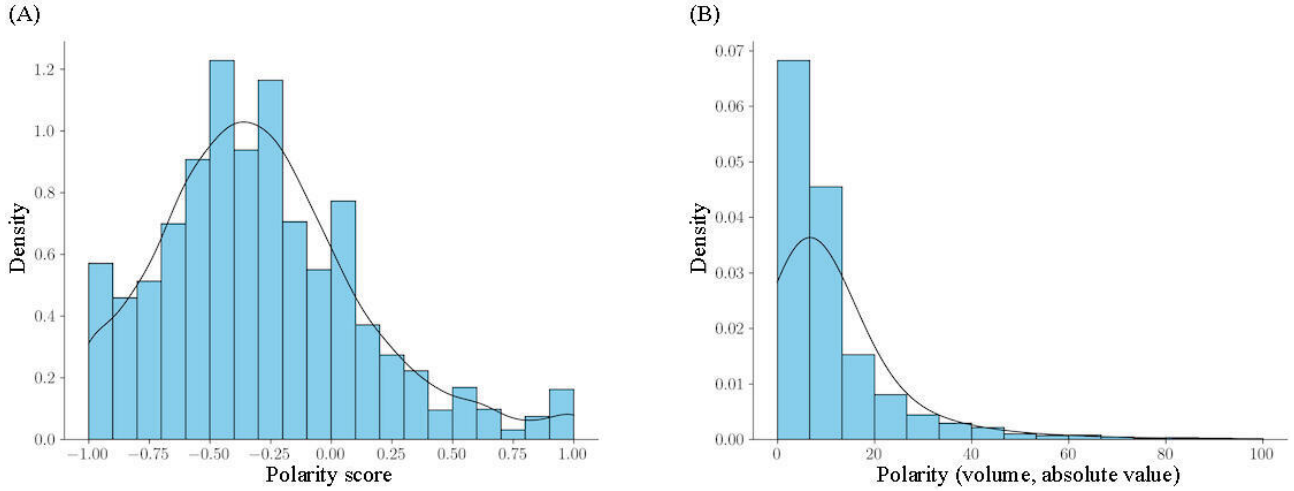
The diffusion of information is traditionally measured in 3 ways: breadth, depth, and speed. These 3 aspects follow previously defined measurements on diffusion on social media platforms [18]. However, given the structure of the PTT forum, depth is unascertainable. The reason for this is because, in PTT, replies of replied posts always refer to the original post, and not the replied post. This metadata obscures the length of the diffusion chain. Compare this to platforms like X (formerly Twitter) that link the diffusion chain through explicitly stating a "retweet" of a "retweet" is "retweeted" from the "retweet," and not the original tweet. Due to the structure in PTT, breadth will be used to capture the size of the information diffusion. Breadth is the number of first-degree child nodes that repost it. If we denote a message as m and the set of first-degree child nodes as $N(m)$, the breadth $B(m)$ is equivalent to $|N(m)|$.

In addition, a negative binomial regression model will estimate the predictors of breadth. A negative binomial regression is used since overdispersion is expected for the distribution of breadth of information diffusion. To build the model, the categorical misinformation types will be input as categorical variables, with "true information" as the baseline. Besides, the polarity score generated in the next section will be used. Polarity is included because it is possible that users who tend to be extreme on either spectrum are likely to have more engagement

XSL•FO
RenderX

in the network. In addition, 2 control variables will be used, including the word count of the post and the activeness of the users. Previous research has suggested that longer posts have a higher likelihood of being transmitted [43]. The activeness of a user is operationalized as the number of historical posts. Although activity on a media platform does not necessarily mean higher engagement [44], it is an important confounding factor to be included in the model. The regression model estimate is: $\log(\mu_i) = \beta_0 + \beta_1(Misinformation) + \beta_2(Disinformation) + \beta_3(Propaganda) + \beta_4(Fabricated) + \beta_5(Propaganda) + \beta_6(WordCount) + \beta_7(UserActiveness) + \beta_8(PolarityScore) + \varepsilon$.

where μ_i is the count of the dependent variable for the i^{th} observation of breadth of misinformation spread. The log link function relates the mean of the response variable to the linear predictors. Variables are tested for multicollinearity prior to inclusion into the model. For a deeper analysis into the variable correlations, see Multimedia Appendix 2. Given that there is no offset term in the regression, the results of the negative binomial regression produce a relative risk (RR) indicating the increased risk of the outcome variable.



Measuring Polarity

Polarization in public opinion refers to the extent to which the views of a population (in this case, support for true or false information) are extreme and distinctly divided [45]. In the context of this study, polarity represents the predominant commenting activity on either true or false information (ie, misinformation), suggesting that users are chambered in their engagement with certain types of information. This measure aligns with the "affective polarization" measures previously used in the politics [23,24] and vaccine sentiment literature; however, they are extended to this study to measure endorsement of either true or false information. Further, polarization can be measured at the individual level or aggregated at the community level. In this study, we measure individuals' level of polarity, proposing 2 metrics for analysis.

The first is polarity measured by the difference in proportion of comments on true information and misinformation ("proportion polarity"). To measure this, we collected the commenting behavior for each node v in the network. With their commenting history, $C(v)$, we calculated the number of comments on true and false information, denoted as $C_{pos}(v)$ and $C_{neg}(v)$, respectively. The proportions of positive and negative comments were then Pposv=Cpos(v)C(v) and Pnegv=CnegvC(v), respectively. We subtracted the proportion of negative comments from the proportion of positive comments to get the polarity score, $\pi_{prop}(v)$, per node using the equation $\pi_{prop}(v) = P_{pos}(v) - P_{neg}(v)$. The range of $\pi_{prop}(v)$ is $-1 \leq \pi_{prop}(v) \leq 1$, with a score of −1 representing a polarity in commenting only on false information, 0 representing equal commenting on both, and 1 representing entirely commenting on true information.

The second is polarity measured by the absolute value of the difference in volume of comments on true and false information ("volume polarity"). Measuring by absolute value of the difference removes the true-false dichotomy and allows a straightforward interpretation of any polarity in the network, permitting a clearer interpretation of echo chambering. To calculate volume polarity, $\pi_{vol}(v)$, we took the absolute value of the difference of the number of negative to positive comments, $|C_{neg}(v) - C_{pos}(v)$. The range of $\pi_{vol}(v)$ is then $0 \leq \pi_{vol}(v) < inf$, with higher values indicating higher polarity. Figure 1 illustrates the distribution in polarity scores calculated by proportion (Figure 1A) and volume (Figure 1B) for the core network. For ease of interpretation in the negative binomial regression, volume polarity value is min-max normalized to create a value between 0 and 1 due to the expected heavier left skew. To preserve the weight of posting in information diffusion, we use the polarity by volume in our following analyses.

Figure 1. Distribution of polarity scores (n=2422) calculated by (A) proportion and (B) volume for the core network.

Node-Level Predictors of Polarity

Influential users generally have disproportionate impact on the flow of network information, also shown in the previous section. Identifying them and their relation to polarity in the network is therefore an important step in diminishing the spread of misinformation. Measures of centrality are usually used to identify node importance in the network. We used 2 centrality

XSL•FO
RenderX

metrics to identify influential nodes, with each representing a different concept of influence.

The first measure of centrality is degree centrality, which directly measures the number of connections a node has. The more connections a node has, the more central and influential it is within the network. In PTT, since forum data is directional, the indegree and outdegree of a node will be calculated for each node separately. Decomposing degrees into indegrees and outdegrees helps distinguish whether nodes on either polar end are more an authority (indegree) or a broadcaster (outdegree) of misinformation.

The second measure of centrality is betweenness centrality, which measure the extent to which a node lies on paths between other nodes; specifically, capturing the frequency with which a node appears on the shortest paths between pairs of nodes. Nodes with high betweenness centrality have control over information flow in the network, acting as "bridges" or "brokers" across the network [46]. These nodes are critical for the flow of information in the network because they function as "switches" for facilitating or inhibiting information flow. For the network, let σ_{st} denote the total number of shortest paths from node *s* to node *t*, and $\sigma_{st}(v)$ denote the number of those paths that pass through a node *v*. The betweenness centrality *b*(*v*) can be defined as:

$$\sum s \neq v \neq t \sigma st(v) \sigma st$$

which sums over all pairs of nodes (*s*,*t*) in the network, excluding those for which the pair is *v*, and for each pair, calculates the fraction of shortest paths between *s* and *t* that pass through *v*. Said another way, it calculates the proportion of times *v* is a bridge along the shortest path between 2 other nodes.

To analyze how polarity in the network changes in response to these influencers in misinformation diffusion, we removed a subset of the percentage of top influential users—by increasing increments of 5%—and calculated and plotted the average absolute value polarity score in the network. The resulting graphs of changing polarity indicate the change in overall posting behavior on either true or misinformative threads by influential users.

Ethical Considerations

This study involved the analysis of secondary data collected from publicly available social media platforms. The data were obtained from PTT, an open-access online forum, and all posts were publicly accessible at the time of data collection. No private or sensitive information was collected, and all user data were anonymized before analysis. The study did not involve any interaction with the individuals behind the social media accounts, and no identifiable information is included in the results. All findings are presented in aggregate to ensure anonymity. As the research only analyzed publicly available data and did not involve human subjects directly, formal ethics approval was not required according to institutional guidelines. Nonetheless, the study adhered to ethical principles of data privacy and responsible handling of social media data.

Results

Identified Misinformation

The results in Table 2 show the number of boards by each misinformation type in Table 1, in addition to an elaboration of several of the most common thread types. Out of 5818 threads, most threads (n=2227, 38.3%) involved netizens asking questions for further clarification on vaccines. The next most common was reporting of official news reports or press conference news (n=1603, 27.8%). For all threads containing misinformation, the most common was the "propaganda" type (n=858, 14.7%), indicating the relatively political nature of this forum. After disregarding the unrelated and religious threads, and recategorizing the "mixed" threads into the conspiracy category, there were 3830 true threads and 1601 threads containing misinformation, for a total of 5431 boards for analysis moving forward. For these boards, the number of comments and reposts for true and false information is illustrated in Table 3.

XSL•FO
RenderX

Table . Counts and examples of common misinformation types on PTT.

Label	Threads, n (%)	Common types found	Example
True information (n=3830, 65.8%)			
Factual news	1603 (27.6)	Official reports of vaccine side effects from government sites, often containing a "News" tag, with text fully reported. Most report official announcements or press conference news with no expression of opinion.	Title: "[News] Free registration now open! Vaccination booth stationed at the PX Mart near Christmas Land"
Scientifically accurate analytical content	2227 (38.3)	Nonbiased question-asking by "villagers"[a] that do not carry any slant in content, or a tone that instigates comments.	"Recently, there was a debate on vaccination, which we only heard the opposite side to not vaccinate. Yes, there are always safety concerns for any medical technology, and it is not 100% preventive of reinfection, but are there other reasons?"
Misinformation (n=1601, 27.5%)			
Misleading information	452 (7.8)	Appears as a question (or comment) but has negative intentions of misleading the public (without understanding the origin of the intention).	"We are now allowing children to get Moderna vaccines, but the side effects are large. According to Murphy's Law, even if the probability is low, it is still possible. If a child does die, after vaccination, who is responsible? … looking at a dazzling object, it's just tin foil. Behind cute makeup is just powder; even polished nails have dark edges."
Disinformation	97 (1.7)	Linking the vaccine as a direct cause of other diseases or ailments (death, cyborgism, myocarditis, balding, etc), and deriving these conclusions from personal experience.	"A lot of people are experiencing side effects from the vaccine, and if something happens, no one takes responsibility. Young people do not need vaccination since their ability to recover is incredibly strong, right? QQ"
Propaganda	858 (14.7)	Linking the reasons for vaccination to specific political attitudes. Often have the characteristic of replying to news posts, guided by personal opinions to specific political positions.	"The 'Taliban'[b] really is ahead internationally, even half of their supporters refuse to roll up their sleeves for Medigen [Taiwan's domestic vaccine]. But maybe they can use it for a bath? The party can enjoy a good bath in their benevolent fluid"
Fabricated content	195 (3.4)	Making nonfactual statements or describing stories related to vaccines based on unwarranted assumptions. Often begins with statements such as "I dreamed that..." or "My friend did..." It is difficult to verify the level of fabrication through text.	"Recently, a female college went to her OBGYN after her Moderna injection. She said her menstruation came twice a month. Some people also said after BNT, the heart was uncomfortable, and took a few days to pass. Why are there still people taking the third dose of MRNA? What's the gossip?"

XSL•FO
RenderX

Label	Threads, n (%)	Common types found	Example
Conspiracy	179 (3.1)	Linking vaccine administration or distribution with the hidden interests of the government and pharmaceutical companies. Mostly done along the lines of them achieving the "benefits" of controlling people if they control vaccine distribution.	"The original vaccines are developed using the original virus, but the virus is constantly mutating. Vaccine factories are not quick to develop new ones, and just encourage us to take booster doses. Isn't this just being done to cheat us of our money? Just like Intel, slowly squeezing out toothpaste, then launching the next generation of products when they can no longer make money."
Mixed misinformation	29 (0.5)	Most cases of 2 or more involved some analytical component, used in a propaganda way.	—[c]
Religious beliefs	23 (0.4)	Adding religious slogans or arguments after raising vaccine-related views. In some texts, elaborated arguments include the viewpoints of a "false world" or "unknown forces." Could also be categorized as broadly conspiracy, with religious grounding.	"I believe [username] now. He said that vaccines are all planned to change human beings. Viruses are man-made and everything is planned. He said the heart used to be on the left side of the body, and now it's in the center according to Google. I'm convinced. I do not want the vaccine. Do you believe [username]?"
Unrelated	155 (2.7)	—	—

[a]Villagers is a common term used on PTT that roughly translates to netizens.

[b]"Taliban" is a derogatory internet slang term that refers to the Democratic Progressive Party or "green" party in Taiwan. The Mandarin Chinese term substitutes the "li" in "Taliban" for the homophonic sound for "green."

[c]Not applicable.

Table . Number of comments and reposts by true information and misinformation.

	Average number of comments	Average number of reposts
True information	74.01	0.40
Misinformation	52.63	0.20
Misleading information	52.63	0.20
Disinformation	75.16	0.16
Propaganda	66.63	0.39
Fabricated content	50.21	0.20
Conspiracy theories	51.41	0.26

Based on our coding and descriptive analysis of the different types of misinformation, we found that the narratives in Taiwan closely resemble those observed in Western contexts. One example is the conspiracy theory that vaccination is used as a means of control by governments or corporations [47,48]. Broadly speaking, these are symptoms of an overarching lack of trust in authorities on health, and part of the larger antiscience trend [48-52]. This point is potentially exacerbated in geopolitically tense contexts such as Taiwan. One such example was the many narratives of faulty quality control prevalent for the Pfizer BioNTech vaccine, since its distributor for Greater China, Fosun, was Shanghai-based, and vaccines were refused as a result. The frequent discussion about and linking of vaccine decisions and political parties (66.63 comments per board, 0.39 average reposts, Table 3) also corroborates this point, and it is also a trend found in the United States. As a side note, the United States and Taiwan share similar forms of government systems, as well as bipartisan polarization.

The following analyses use the core network. In the entire network, there were 23,004 unique users, with the average polarity (by volume) being 3.27. The core network is relatively smaller and more polarized than the entire network, with 6035 unique users with an average polarity of 8.70.

Diffusion of Misinformation

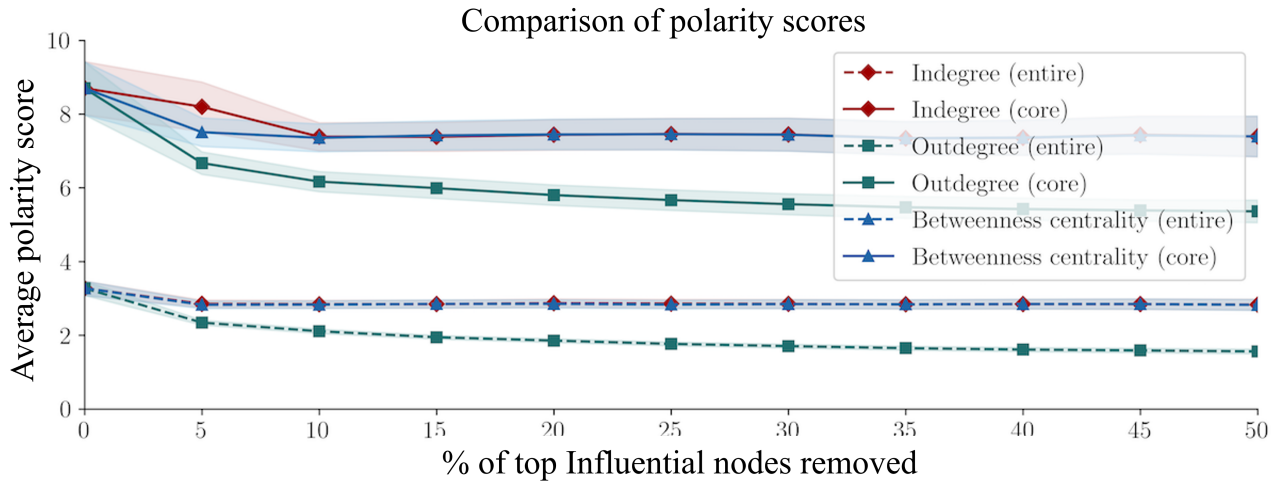
Overall, the average word count of posts was 525.5 words while the median was 326.0, indicating a heavy right tail. The same trend was observed for the activeness of the user, with an average of 279.3 engagements—any posts or comments—compared to a median of 129.0. The polarity score

XSL•FO
RenderX

of the core network is long-tail distributed, and it has an average of 38.2 but a median of 4 (Figure 1). For breadth, among threads identified containing true information, 608 (15.9%) were shared at least once. Conversely, 165 (10.3%) of misinformative threads were reposted. There is no statistical difference between the average repost counts across true information and misinformation, with means of 2.39 and 2.33 reposts for true information and misinformation, respectively (t=0.250; P=.803). The 95% confidence interval for the 2 values ranged from −2.2 to 29.1 for true information threads and −1.1 to 10.3 for misinformation threads.

Table 4 presents negative binomial regression results of predicting breadth of information diffusion. As can be seen, the RR of repost for propaganda information is double that of true information (RR=2.07; P<.001). The risk of reposting disinformation is half that of true information (RR=0.48; P=.001). Moreover, posts from more polarized users (RR=0.22; P<.001) do not arouse as much discussion, suggesting the forum is relatively averse to echo chambering in relation to misinformation.

Table . Predictors of breadth (n=2422).



Variables	Breadth		
	Exp(coef)	SE	*P* value
Information type			
True information (baseline)	N/A[a]		
Misleading information	1.10	0.085	.28
Disinformation	0.48	0.227	.001
Propaganda	2.07	0.063	<.001
Fabricate information	0.79	0.156	.12
Conspiracy theories	1.23	0.132	.12
Polarity of user	0.22	0.202	<.001
Control variables			
Word count (of post)	1.0002	0.25×10^{-4}	<.001
User activeness (number of historical posts)	0.998	0.53×10^{-4}	.001

[a]Not applicable.

Node-Level Predictors of Polarity

We also examined whether removing influential users would contribute to decreasing polarization in the misinformation diffusion network. Figure 2 shows the changes of polarity scores for the entire network and the core network of more than 5 posts. The first finding is that, overall, the entire network is less polarized than the core network, as exemplified by the lower average polarity score. This means most of the active users are polarized; they will post predominantly on exclusively true information or misinformation threads. The second finding is that the average polarity score of the network decreased as the most influential users of the network were removed (the top 5% in the entire network and the top 10% in the core network). The 95% confidence intervals are generated from t tests testing the difference in means, with no overlap suggesting significance.

Figure 2. Impact of removing top percent of influential nodes on network (polarity score calculation: absolute value of volume).

XSL•FO
RenderX

These results suggest several trends. The first is that the core network exhibits more echo chambering in its behavior. Thus, those that are more influential on PTT are more likely to be more polarized, gravitating toward true or false information. However, when interpreted in conjunction with the regression results, posts from polarized users were likely to arouse less attention, suggesting that polarized users are more active and influential in commenting instead of posting. The second is that polarization happens with a few key users. In the core network, when the top 10% of nodes using any metric are cut, the polarity score decreases sharply. After 10%, the rate of decrease tapers off. The steeper declines for outdegree and betweenness centrality suggest that identifying active commenters and brokers in the network may be more useful than identifying those that receive many comments.

Discussion

Principal Findings

This study aims to explore vaccine misinformation in Taiwan in 3 ways. The first is by cataloging the types of vaccine misinformation encountered during the pandemic. The second is comparing the diffusion of different types of misinformation. The third is measuring how influential users contribute to the level of polarity of the discussion forum. Overall, the results show that propaganda-style misinformation (RR=2.07; $P<.05$) has wider diffusion, whereas polarized users (RR=0.22; $P<.001$) received less attention for their posts. In addition, by removing the most influential users in the misinformation diffusion network, measured by indegree, outdegree, and betweenness centrality, the average polarity of the entire network decreased. This suggests a potential strategy to combating the echo chamber effect in misinformation by targeting the influential users.

The results from the regression supplement the literature on misinformation virality [53] that suggests that misinformation type may contribute to differences in diffusion. Misinformation propagated with political propaganda intentions has a higher rate of reposting compared to true information. This, in part, could be due to the nature of the PTT forum, which is a heavily politicized forum. In the broader echo chamber literature on science, there are growing concerns of politically aligned selective exposure in science. A study by Nisbet et al [54] focusing on the United States found that, regardless of political affiliation, there are negative and emotionally loaded reactions to dissonant science communication. The downstream effects of these trends are drastic in that overall trust of the scientific community diminishes. Some studies posit that this is due to a phenomenon of “elite cues” in which public opinion follows the elites’ partisan battles on the specific issue, such as shown in the climate change debate in the United States [55,56]. Another closer example to vaccination is Hamilton and Safford’s study [57] on trust in the US CDC among Republicans following Donald Trump’s changing views toward the CDC. Although this study does not analyze elite cues, the same trend may also be true for Taiwan, which has political systems very similar to the United States in terms of bipartisanship and polarization. A most recent cross-national study further suggests the close relationship between individuals’ voting choices and their conspiracy beliefs during the COVID-19 pandemic [58]. A further study on the narratives in the propaganda stream is one next step toward corroborating these trends in the literature, and enriching it by providing analysis from a different perspective.

Other than propaganda-based misinformation, the finding that disinformation was reposted less also reinforces that certain streams of misinformation may have more viral potential than others. On content, the findings corroborate other literature findings of longer posts being more transmissible. Posts with longer text are more likely to be spread [43]. However, more active users generally have proportionally less of their boards arouse attention, a finding different from other platforms like X [44]. This could be a natural trend for users whose post volumes are high.

Other findings similar to previous studies include the more prevalent engagement with misinformation compared to true information [59-62], as suggested by the skew of the graph in Figure 1A. This is true despite most boards containing true information. However, the diffusion of true information and misinformation is the same, as seen in Table 4. In addition, this study finds that most misinformation streams also tend to be in either vaccine hesitant or antivaccination stance boards [63-65], a finding not surprising given the affinity of misinformation to an antivaccination agenda [66]. Another new finding is that “brokers” of forum information—influential users as measured by betweenness—disproportionately engage with true information or misinformation across the entire network, suggesting that they are the polarizing forces in the echo chambering of misinformation. These results highlight the importance of measuring polarity in endorsement of misinformation for vaccine hesitancy, an aspect previously underexplored in the literature. By analyzing the polarized endorsement of misinformation, we gain insights into the formation of echo chambers of misinformation arising in a forum and can devise strategies for managing them. The findings for PTT suggest 2 main modes of moving forward in vaccine misinformation management for Taiwan.

The first is the implementation of a consolidated, automatic early detection system of online media potentially containing vaccine misinformation. Much like a disease surveillance system, a misinformation surveillance system should be able to detect and flag potential misinformation early such that its transmission is inhibited if necessary. The reason this is useful is because of the seeming affinity that misinformation has in attracting users, which is more dangerous when those users are influential. Once detected, this information can be used to inform the public as a means of “psychological inoculation” to help internet users better discern misinformation [67]. Given that the narratives of misinformation are not novel in Taiwan, this system can be trained using global reports of vaccine-related misinformation in addition to the civilian-led misinformation clarification platforms already present in Taiwan (MyGoPen, CoFacts, etc). This management system would be particularly important during outbreaks or other flashpoints as online information often peaks as a response to events [68-71]. As a step in infodemic management, it would help improve health literacy.

XSL•FO
RenderX

The second is to create a system that can identify then neutralize influential brokers (ie, high betweenness centrality) and commenters (ie, high outdegree) who have high interactions with misinformation posts. This can reduce the polarity in the network away from negative polarity. In this study, their connectivity means that neutralization may reduce the polarity of the network. Identifying users that are either antivaccination or spreaders of misinformation using these metrics represents an untapped potential for positive engagement that continually breaks the echo chamber effect for both vaccine stance and misinformation spread.

Although the technical aspects of such a system are relatively straightforward, the challenge extends beyond just technical regulation and public health, requiring the balancing of ethical considerations in moderating harmful information without impinging on free speech. This moral dilemma has been studied in other contexts, such as politics and culture [72,73], suggesting that the public supports misinformation management if it causes harm, defined as something undermining people's ability to make informed decisions (particularly around public health and elections) [74]. Studies on the association of misinformation and vaccine intention suggest that they are negatively correlated [15,75]. Other considerations are the scope of required management, such as removal of posts or the temporary or permanent suspension of users. During the COVID-19 pandemic, many social media platforms (eg, Facebook, Instagram) assumed this regulatory role and intervened to prevent the spread of misinformation and conspiracies around vaccines. However, in Taiwan, no such action was taken to actively manage misinformation on local platforms. Rather, the government provided information platforms as secondary references for those already exposed. Moving forward, misinformation management should constitute part of the overall architecture for epidemic management in Taiwan, a process likely to involve fierce democratic discussion or debate on the moral dilemma of speech regulation.

Limitations

A significant limitation of this study is its focus on a single platform, PTT, which may not be representative of the broader online landscape in Taiwan. PTT's user base is distinct in its demographics and its heavily politicized nature, which could skew the findings on the spread of vaccine misinformation and its interaction with user behavior. As such, the results may not fully capture how misinformation diffuses across other popular platforms like Facebook, LINE, or Instagram, which have different user profiles and communication dynamics. Future research could address this limitation by conducting comparative studies across multiple social media platforms to gain a more comprehensive understanding of misinformation diffusion.

Another limitation stems from the use of social media data, which inherently introduces challenges related to user anonymity and the authenticity of user identities. Social media platforms often allow for pseudonymous accounts, making it difficult to verify whether the key users identified in this study are representative of broader population segments or if they include bots or automated accounts, which are known to play a role in the spread of misinformation. Additionally, social media data are typically unstructured, which presents challenges in accurately capturing the context, sentiment, and intent behind posts. This study relied on manual coding, which, despite high intercoder reliability, is subject to human bias. Incorporating more automated methods, such as natural language processing, could reduce bias and improve the scalability of the analysis. Moreover, the rapidly evolving nature of social media platforms, algorithms, and user behavior means that findings based on past data may not hold in future contexts, making longitudinal studies crucial for a more dynamic understanding of misinformation patterns over time.

Conclusion

This study provides key insights into the dynamics of vaccine misinformation in Taiwan, highlighting the influence of core users in spreading polarizing content and the different diffusion patterns between true information and misinformation. The findings underscore the potential for targeted interventions, such as identifying and neutralizing influential users who propagate misinformation, as a means of reducing network polarization and improving public health outcomes. By addressing the mechanisms of misinformation diffusion and understanding the role of user behavior in its propagation, this research contributes to the broader effort to combat misinformation in digital spaces and enhance public trust in scientific communication. Future studies can build on these findings by extending the analysis to other platforms and exploring cross-national comparisons to generalize the results.

Abstract

Background: During the COVID-19 pandemic, social media platforms have been a venue for the exchange of messages, including those related to fake news. There are also accounts programmed to disseminate and amplify specific messages, which can affect individual decision-making and present new challenges for public health.

Objective: This study aimed to analyze how social bots use hashtags compared to human users on topics related to misinformation during the outbreak of the COVID-19 pandemic.

Methods: We selected posts on specific topics related to infodemics such as vaccines, hydroxychloroquine, military, conspiracy, laboratory, Bill Gates, 5G, and UV. We built a network based on the co-occurrence of hashtags and classified the posts based on their source. Using network analysis and community detection algorithms, we identified hashtags that tend to appear together in messages. For each topic, we extracted the most relevant subtopic communities, which are groups of interconnected hashtags.

Results: The distribution of bots and nonbots in each of these communities was uneven, with some sets of hashtags being more common among accounts classified as bots or nonbots. Hashtags related to the Trump and QAnon social movements were common among bots, and specific hashtags with anti-Asian sentiments were also identified. In the subcommunities most populated by bots in the case of vaccines, the group of hashtags including #billgates, #pandemic, and #china was among the most common.

Conclusions: The use of certain hashtags varies depending on the source, and some hashtags are used for different purposes. Understanding these patterns may help address the spread of health misinformation on social media networks.

Introduction

From the swine influenza (H1N1) pandemic in 2009 to the subsequent outbreak of the H7N9 virus, also known as bird flu, in 2013, Twitter (subsequently rebranded as X) has increasingly become a popular platform for sharing health information [1,2]. Using posts, users can express their thoughts and opinions on many health topics. That is why specific interaction tasks have

XSL•FO
RenderX

attracted the attention of researchers. This research can inform public policy by encouraging governments and health care professionals to allocate necessary resources, act, and plan accordingly [3,4]. These social media platforms have played a crucial role in providing information to the public during the COVID-19 pandemic. However, there was an increase in low-quality information, as well as the infodemic phenomenon. The infodemic, defined as an excess of information that makes it difficult for people to find reliable sources [5], can have harmful consequences [6].

The COVID-19 pandemic triggered mandatory lockdowns, social distancing, quarantines, and SARS-CoV-2–protective measures that would give rise to all sorts of opinions and behaviors [7]. During the COVID-19 pandemic, mandatory lockouts drastically altered people's daily routines (work, travel, and leisure activities) to levels never before experienced by the populations of the different countries affected by the new disease [8]. The state of uncertainty in the face of an invisible threat would transform previously normal situations into situations of risk. Direct social interaction with people outside the nuclear family, attending a concert, meeting for dinner with friends and family, shaking hands with someone, and even hugging or kissing became exceptional situations during the most uncertain periods of the pandemic—situations that, as has been observed retrospectively, would have a significant impact on the mental health of the population [9]. Likewise, the health crisis gave rise to the infodemic that, through social media platforms, opened the door to fake news, misconceptions, hoaxes, and anecdotal evidence about the origin of the pandemic, the social agents to blame for the situation, and the possible measures to be taken at a time of maximum uncertainty [10].

To understand how during the new context of health emergency misinformation spreads on these platforms, studies analyzed different elements, including the quality of information sources through URL analysis; identification of topics that generate misinformation; and analysis of online communities that spread misinformation, such as the antivaccine movement [11-14]. Others focused on the use of hashtags to describe the organization of the debate around the COVID-19–related topics. Researchers examined the frequency of use and the topic analysis of hashtags, and emphasized their main role in certain conversations [15,16]. By analyzing specific hashtags, studies also demonstrated how antivaccine communities, the proliferation of racist sentiments, or the spread of conspiracy theories are articulated on social media [17-19]. Some studies paid particular attention to how hashtags were used or combined in online conversations about the COVID-19 pandemic, using clustering techniques to describe the themes and combining hashtags with semantic text analysis and natural language processing (NLP) methods to improve topic modeling [20-22]. In addition, social network analysis (SNA) became useful to examine the co-occurrence of hashtags [23]. These studies demonstrate how the combination of different approach is useful to analyze online conversations more thoroughly.

Recently, the role of social bots has contributed to the spread of misinformation on social media platforms in various ways [24]. This issue garnered more attention as fake news and misinformation were significant factors during the COVID-19 pandemic. In this sense, some studies analyzed the role of bots regarding the spread of misinformation in general, while others have focused specifically on topics such as vaccines, conspiracy theories, hate speech, or reactions to other political actions [25-31]. However, a small amount of research compared the behavior of bots and humans [32,33].

To better understand the influence of bots on social media conversations, a previous study used topic modeling to segment the Twitter conversation and compare differences between accounts [34]. Nevertheless, the analysis did not focus on the usage of hashtags, which is the primary focus of this study. We aim to identify patterns and trends in hashtag usage to describe how bots and nonbots differ in their use of hashtags.

Only a few studies analyzed how social media bots use hashtags compared to humans. Most studies in this field examine specific hashtags [17-19,35-37]. To address this knowledge gap, we explore how social bots use hashtags specifically in connection with certain infodemic topics, issues that contribute to the generation or spread of fake news, misinformation, or discriminatory narratives. By analyzing how frequently hashtags co-occur, we aim to understand how they appear in the conversation and how they are combined. Besides, we also considered the context in which hashtags are used. They can be used ironically or convey disagreement. Our goal is to address three key questions: (1) What are the most common hashtag co-occurrences? (2) What are the differences in hashtag usage between bots and nonbots? and (3) Do bots and nonbots use certain hashtags in different ways?

Methods

Data Collection

Data collection for this study took place from March 16 to June 15, 2020, using the Twitter Streaming application programming interface (API). The hashtags #covid_19, #covid19, #covid, and #coronavirus were used to capture conversations about the first wave of COVID-19 pandemic, and only English-language posts were selected.

Based on previous research, we created a list of topics that were commonly associated with fake news or misinformation. This list includes ozone, laboratory, 5G, conspiracy, Bill Gates, milk, military, and UV. Vaccines were also identified as a controversial topic in multiple studies, so we added them to the list [38-40].

Ethical Considerations

The present study was approved by the Ethics Committee of the University of Cadiz (005_2024).

Bot Classification

To identify whether accounts on Twitter were bots or not, we used Botometer by OsoMe (formerly known as BotOrNot) [41]. This publicly available application uses over a thousand criteria to determine how closely a Twitter account matches the typical characteristics of social bots.

To create a binary classification (bot or nonbot) and prioritize identifying true positives over true negatives, we set a threshold

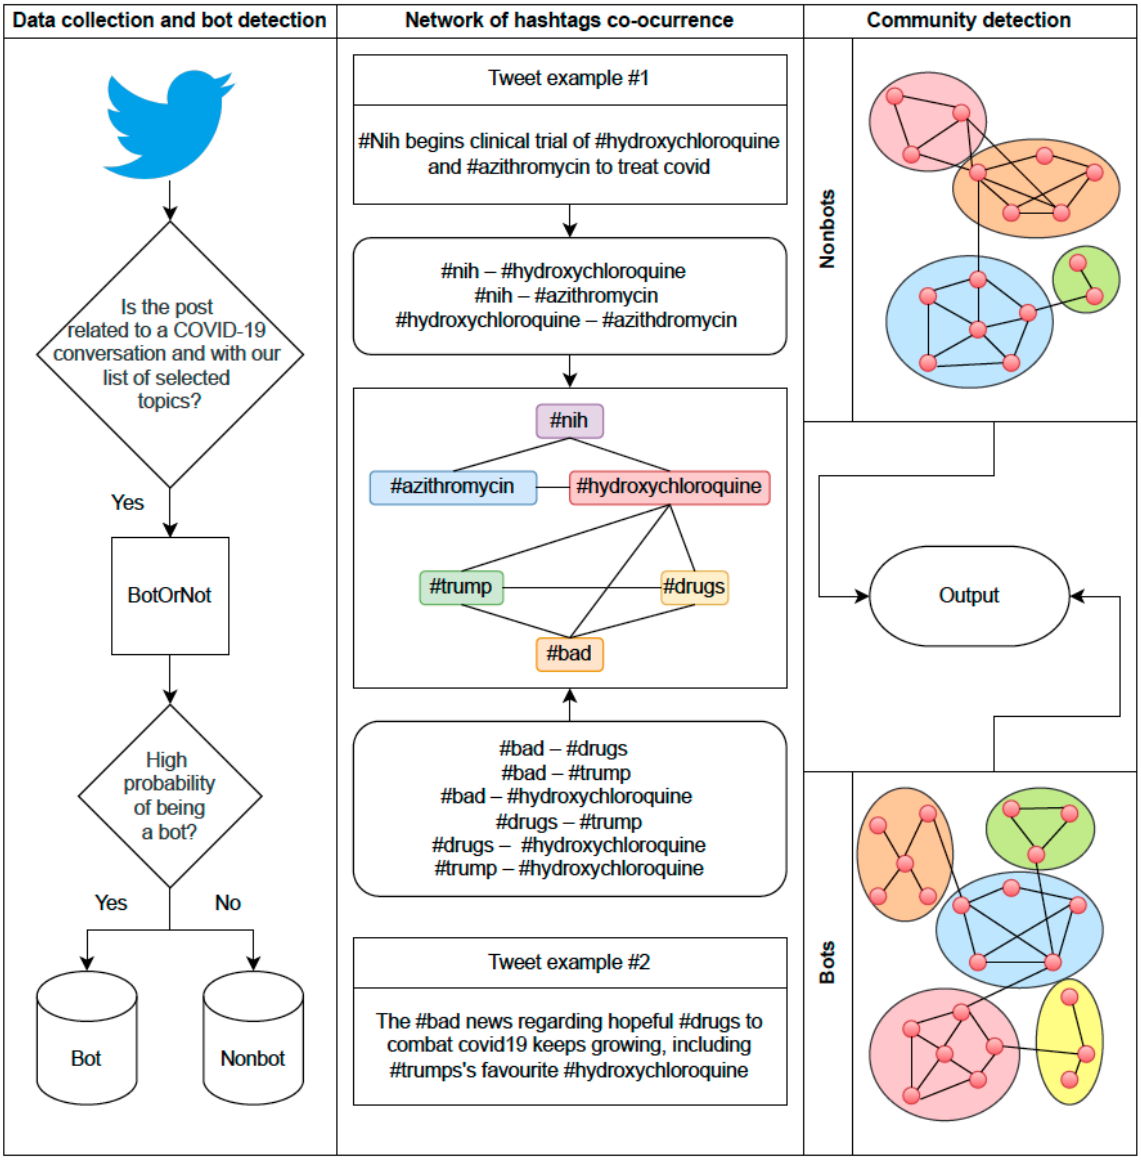
XSL•FO
RenderX

value of 0.8 [34]. Using this threshold, we classified approximately 14.8% of the accounts as bots, which is in line with the findings of other research that found bot levels to be between 9% and 15% of the total number of Twitter accounts [42].

Botometer also provides rankings for 6 main types of bots, including echo-chamber, fake follower, financial, self-declared, spammer, and others, in addition to the overall likelihood of being a bot. In this study, we focused on analyzing the behavior of social bot accounts, particularly those that were not identified as automated accounts. These types of accounts are often associated with press agencies, companies, newspapers, or journals, and their primary purpose is to automatically publish information about a specific topic. These accounts may indicate that they are automated, for example, by including the word "bot" in their screen name or being identified as bots on Botwiki [41]. Therefore, we chose to exclude self-declared bots from our analysis due to their different characteristics compared with other social bots [41].

For this study, we classified accounts as nonbots if their probability of being a bot was less than 0.8, as self-declared bots if their probability of being a self-declared bot was greater than 0.8, and as bots if their probability of being a bot was greater than 0.8 and their probability of being a self-declared bot was less than 0.8. We then filtered out self-declared bots and considered both bots and nonbots for analysis.

Network Analysis



To identify patterns in the usage of hashtags, we applied network analysis. We constructed a network by analyzing the co-occurrence of hashtags in posts and comparing the use of hashtags by bots and nonbots. In the network, hashtags were represented as nodes, and they were connected if they appeared in the same post. The weight of the connection between 2 hashtags was determined by the number of times they co-occurred.

We also calculated various metrics of connection, distribution, and segmentation of the hashtag network. We used the PageRank algorithm to identify the most important nodes in the network and the degree value, which represents the number of connections each hashtag has [43]. We also used the betweenness metric, which measures centrality [44]. In addition, we used the Louvain algorithm to detect the most important communities in the network. This algorithm maximizes a modularity score for each community, where the modularity measures the quality of the assignment of nodes to communities. This allowed us to identify hashtags that often co-occur together. We computed each metric separately considering whether the hashtags appear in posts posted by a bot or a nonbot. Figure 1 contains a flow diagram for the entire process.

In the following section, we first present the results for the entire network. In the following subsections, 1 for each topic, we segment the overall network of hashtag co-occurrences by extracting posts that specifically mention words related to each topic. For example, the network for vaccines will show the co-occurrences of all hashtags that appeared in posts about vaccines.

XSL•FO
RenderX

Figure 1. Flowchart from data collection to analysis.

Results

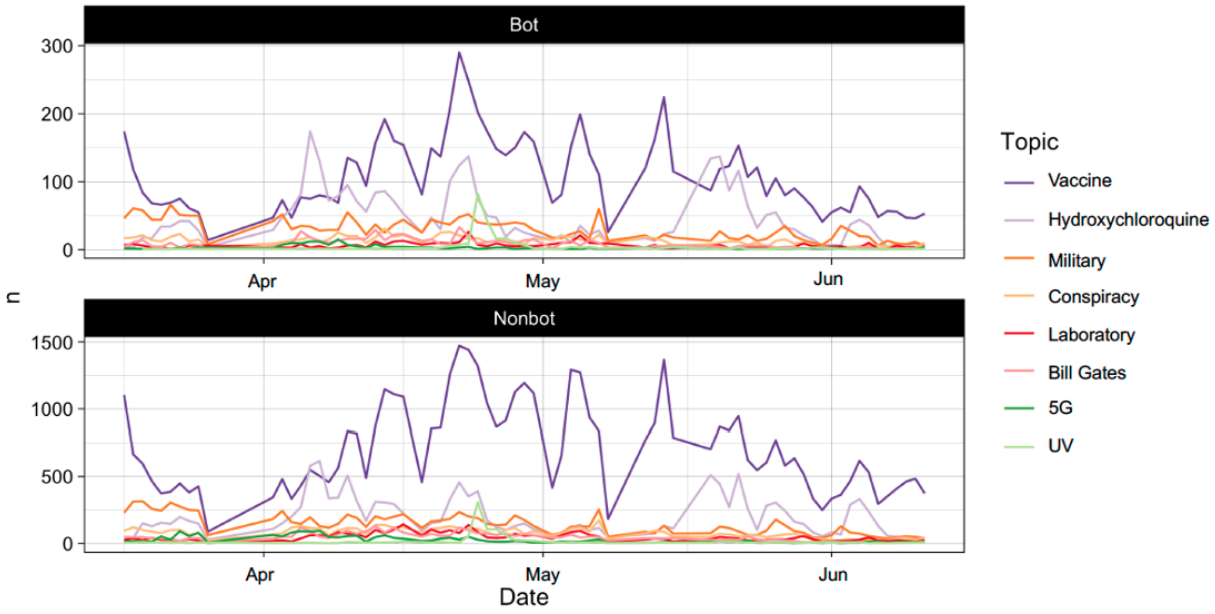
Overview

In total, we extracted around 107,173 posts from March to July 2020 that were related to the topics on our list. Most of these posts were about vaccines (59,090/107,173, 55.1%), hydroxychloroquine (17,731/107,173, 16.5%), or the military (12,548/107,173, 11.5%). Out of all the accounts analyzed, 85.2% (91,311/107,173) were identified with a low likely of being bots, that is, nonbots. Approximately 14.8% (15,862/107,173) of the posts were classified as likely being from bot accounts. As shown in Figure 2, the number of posts related to vaccines was consistently higher throughout the period, except for 2 specific moments. The first of these coincides with a message from US President Donald Trump recommending the use of hydroxychloroquine, an unproven drug. The second date also coincides with a message from Trump suggesting the injection of disinfectant to beat COVID-19 pandemic.

We created a graph of the full network of hashtags. For clarity, we selected a random sample from the entire collection of posts and depicted it in Figure 3. We also applied color to the Louvain communities and highlighted some hashtags that represent the topics analyzed in the study. This process is like the one we used for each topic in the list.

XSL•FO
RenderX

Figure 2. Bot and nonbot distribution by topic and date.



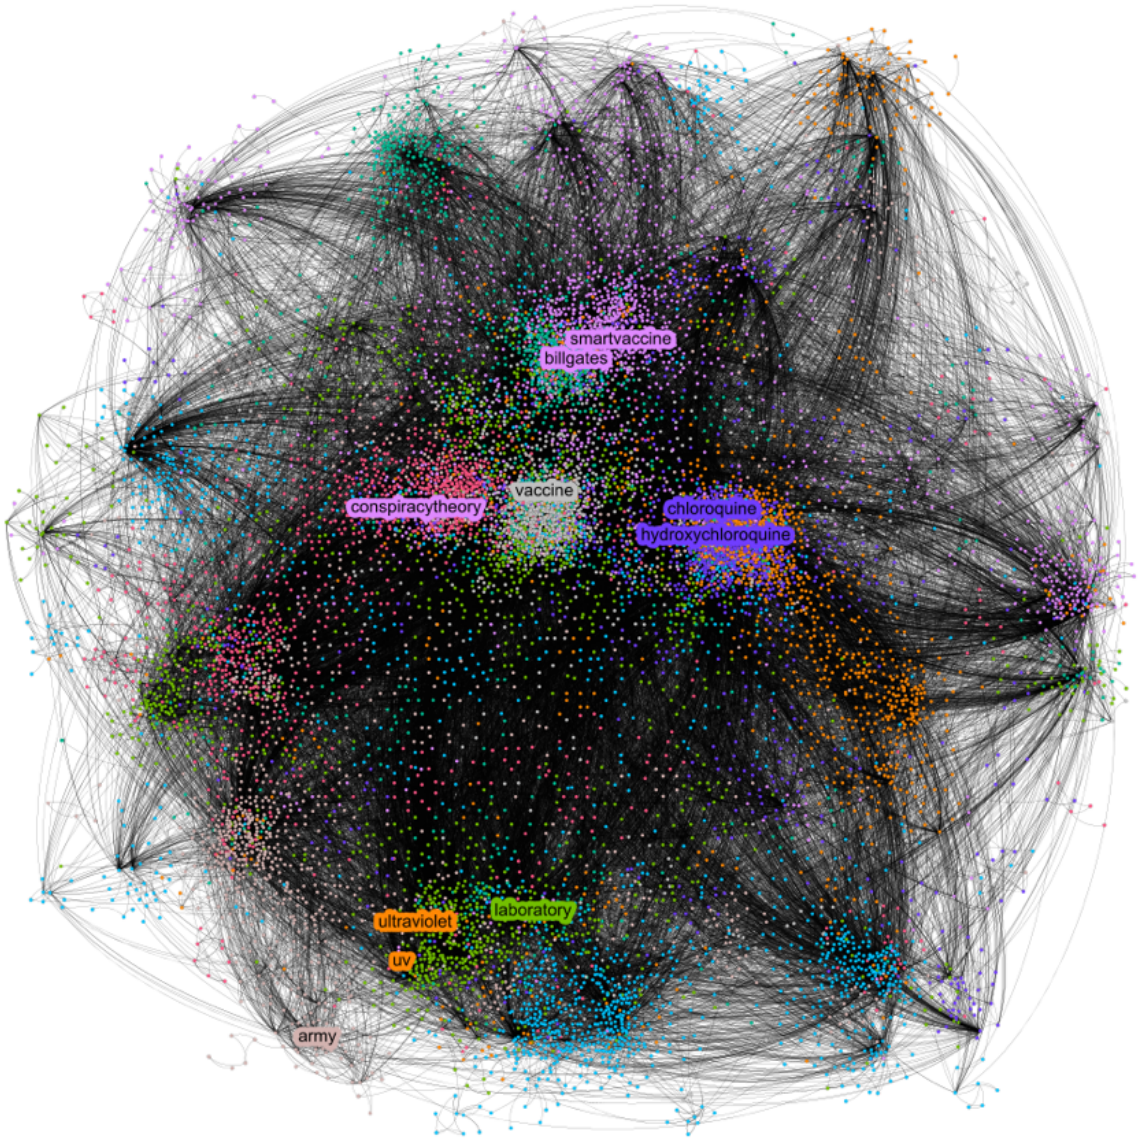


Figure 3. Hashtag network.

XSL•FO
RenderX

In Table 1, we present statistics for the overall hashtags network to provide a broad overview. As mentioned earlier, we calculated the metrics separately for each type of account. There are some differences in the most used hashtags between the 2 groups. For example, hashtags such as #Trump, #China, and #BillGates appear in both groups. However, the hashtag #vaccineswork is one of the most used by nonbots, while the hashtag #lka (which is the country code for Sri Lanka) is more frequently used by bots.

Table 1. Most common co-occurrences by bot and nonbot.

Hashtags	Posts, n (%)
Bots (n=3459)	
#chloroquine - #hydroxychloroquine	537 (15.52)
#hydroxychloroquine - #trump	490 (14.17)
#africaisnotalaboratory - #changeyourworld	437 (12.63)
#azithromycin - #hydroxychloroquine	345 (9.97)
#coronavirushoax - #prisonearth	280 (8.09)
#digitalvirus - #policestate	280 (8.09)
#digitalvirus - #prisonearth	280 (8.09)
#policestate - #prisonearth	280 (8.09)
#coronaviruslockdown - #lockdownextension	267 (7.72)
#changeyourworld - #coronacrisisuk	263 (7.6)
Nonbots (n=665)	
#hydroxychloroquine - #trump	133 (20)
#climatechange - #sustainability	106 (15.94)
#lka - #srilanka	86 (12.93)
#chloroquine - #hydroxychloroquine	84 (12.63)
#azithromycin - #hydroxychloroquine	72 (10.83)
#kag - #maga	53 (7.97)
#pandemic - #vaccine	35 (5.26)
#billgates - #vaccines	33 (4.96)
#kag - #qanon	33 (4.96)
#china - #vaccine	30 (4.51)

There are also some similarities in the co-occurrence of hashtags between the 2 groups. For example, hashtags #hydroxychloroquine and #trump appear in the same posts with higher frequency in both cases, at 14.17% (490/3459) and 20% (133/665), respectively. However, other hashtag pairs such as #kag-#maga, #billgates-#vaccines, or #kag-#qanon are common among bots. “KAG” stands for “Keep America Great,” which was President Trump’s campaign slogan in 2020, while “MAGA” stands for “Make America Great Again,” which was his campaign slogan in 2016. Both slogans have been associated with American nationalism, and the hashtag #MAGA has sometimes been used by white supremacist groups and Trump supporters.

On the other hand, nonbots tend to use other hashtag pairs such as #coronavirushoax-#prisionearth, #digitalvirus-#policestate, and #digitalvirus-#prisionearth. These hashtags, especially “#prisionearth,” were often used ironically to mock false rumors or exaggerations that were circulated online.

Vaccines

The most common co-occurrent hashtags used by nonbots regarding vaccines are #uk-#usa, #research-#science, #vaccineswork-#worldimmunizationweek. However, the most common hashtags in those posts posted by bots are #trump-#votebluetosaveamerica, #healthcare-#ppe, or even #healthcare-#ventilators. In addition, these last mentioned are exclusive of bots. That is, they only co-occur in posts from accounts classified as bots. Besides, it is worth mentioning that #billgates, along with #pandemic or #china, are the hashtags with the highest degree of connections, as seen in Table 2.

The algorithm extracted 5 different communities (Multimedia Appendix 1). We found significant differences in the hashtags that made up the Louvain communities. The first community contains hashtags related to news (#breaking, #usnews, and #breakingnews); countries (#canada, #france, #japan, #spain, and #africa); and others related to fake news like #wuhanvirus, #ccpvirus, #bioweapon, #hiddenhand, #psychopaths, #chinaisassho, and #madeinchina. This community is the most populated by bots, and the difference between bots and nonbots is the highest.

The second community contains hashtags related to famous people (#billgates, #anthonyfauci, and #georgesoros). These include people like Bill Gates and Anthony Fauci who played a leading role by holding provaccine positions. As in the previous case, we also found some hashtags related to fake news or conspiracy theories such as #billgatesisevil, #billgatesvaccine, #vaccinemafia, or #newworldorder. In this community, the quantity of nonbots is slightly higher than the number of bots.

On the other hand, the number of bots is also higher in the third community. In this case, the hashtags mention politics, such as #trump, #biden, and #borisjohnson. In addition, there were also some hashtags related to measures to curb the pandemic, such as #stayhome, #socialdistancing, or #lockdown. Only a few infodemic-related hashtags were found: #methanemouth, #pussygrabber, or #bananarepublic. The number of nonbots is higher in the other 2 communities. The fourth and fifth communities contain hashtags related to research and vaccines (#research, #health, and #medicine) or diseases and public health campaigns (#vaccineswork, #measles, #endpolio, and #healthforall), respectively. In particular, #vaccineswork is a hashtag used by health institutions such as the World Health Organization. Conversations on these hashtags were related to second waves and the importance of vaccines to fight against the COVID-19 pandemic.

Hydroxychloroquine

Hashtags related to Trump and the Republican movement were common in the case of hydroxychloroquine. These hashtags, such as #kag, #maga, #gop, #qanon, and #tcot, were more common in bot posts. Although #trump also appears in the case of nonbots, there were other hashtags related to news: #breaking-#breakingnew and #chinavirus-#wuhanvirus. Consequently, #trump has the highest degree of connection and the one with the highest betweenness. This hashtag, along with #chloroquine or #coronaviruspandemic, is the hashtag with the highest number of connections. There is a big difference between the first and the rest of the hashtags shown in Table 2. This difference indicates the leading role that #trump plays in the conversation about hydroxychloroquine.

We identified 8 different communities (Multimedia Appendix 1). Regarding the composition of the communities, it is worth mentioning the difference between the 2 most important ones. On the one hand, the first contains hashtags related to drugs, vaccines, or the pharmaceutical industry: #azithromycin, #biotech, #chloroquine, #lupus, #malaria, #cdc, or #hcq. In the same line, in the fourth community, the predominance of nonbots is noticeable. This time the hashtags mention countries (#uk, #us, #coronavirusuk, #france, #italy, and #germany), news (#worldnews and #usnews), TV series (#greysanatomy and #littlefireseverywhere), and supporting hashtags (#inthistogether).

On the other hand, in the second community, most of the hashtags are related to Trump or social movements related to him (#trump, #gop, #maga, and #donaldtrump). Nonetheless, some are against him (#notaleader, #worstpresidentinhistory, and #putinpuppet). In addition, the number of bots is higher than the number of nonbots, contrary to what happens in the first one.

Military

In this case, hashtags are related to specific countries that were mentioned during the pandemic. For nonbots, those most mentioned are #china-#us, #italy-#russia, and #lka-#srilanka. The latter is the most common among bots, followed in fourth place by #italy-#russia. Among the sets that do not mention countries, we find hashtags related to Trump (#gop-#trump, #kag-#maga, and #kag-#qanon).

These hashtags have similarities to those of hydroxychloroquine. The bots' unique hashtags are related to the Trump movement or Republican movements (#gop, #kag, and #qanon). In addition, #trump has the highest degree of connectivity and betweenness. This situation is also present in the communities (Multimedia Appendix 1). The first community detected contains hashtags related to Trump, and the second is related to military and veterans (#usmc, #veterans, or #usairforce). In both cases, these relationships take place in posts posted by bots.

Conspiracy

In this group, we found some hashtags related to conspiracy theories (or misinformation) and others related to countries. Regarding bots, the most common hashtags are #fakenews-#technology, #conspiracytheories-#socialmedia, and #donthecon-#trumplies. In line with this, for the nonbots, the most common hashtags are #conspiracytheory-#woke. The hashtags used only by bots are also related to racism (#racism-#sinophobia) or the economic system (#capitalismfails-#socialismworks).

Of the 6 most prominent communities (Multimedia Appendix 1), 3 of them have only nonbots. Topics in these communities are about minority groups (#blackpeople, #lgbt, and #amerikkka), about Trump (#maga, #bananarepublic, and #qanon), and about the pandemic (#coronavirusoutbreak,

XSL•FO
RenderX

#coronaviruspandemic, and #pandemictech). Of the other 3, in the first one, the number of nonbots is slightly higher than the number of bots. Some of the hashtags have to do with conspiracy theories (#conspiracytheory, #disinformation, and #propaganda), media (#qanonnfoxnews, #propaganda, and #fakenews), and others in a derogatory tone (#covidiot, #plandemic, and #plandemicdocumentary). On the other hand, in the second and fifth communities, the numbers of bots are higher. In this case, the most common hashtags are related to countries (#china, #us, and #iran), Iran specifically (#irancovidtruth and #iranregimechange), or against right-wing political parties (#rightwingignorance).

Laboratory

In this case, there are apparent differences in the geographical areas of the most used hashtags. On the one hand, nonbots mostly use #africaisnotalaboratory, while bots use #srilanka and #lka (country code for Sri Lanka). The hashtag #indiafightscorona is also common for bots. The hashtags #china-#wuhan are very common in both cases. This explains why #wuhan is the hashtag with the highest PageRank value and the highest degree of connection (Table 2), followed by #laboratory in second place and #africaisnotalaboratory in third place.

The differences between hashtags and the type of account that wrote the message were very clear in this case. On the one hand, in the first and fourth communities, the presence of bots is higher than nonbots (Multimedia Appendix 1). The first is focused on China, with some examples such as #ccpvirus, #chinamustexplain, or #chinaliedpeopedied, and the second is focused on Southeast Asia, such as #armenia, #abudhabi, or #masdarcity.

Bill Gates

The data from the Bill Gates conversation are similar to those obtained in the case of hydroxychloroquine. Trump-related hashtags were very common (#kag, #maga, and #qanon) in both bots and nonbots. The centrality and degree values are among the highest, as can be seen in Table 2. There were also new hashtags related to this type of political movement that only appears in this conversation, such as #crimesagainsthumanity, #gatesofhell, or #greatawakening. In addition, hashtags disparaging the figure of Bill Gates are also common, such as #saynotobillgates or #billgatesisevil.

We identified 5 communities of hashtags (Multimedia Appendix 1). Among the 3 largest communities, the number of bots is higher than the number of nonbots in the second one. In this community, the most frequent hashtags are #trump, #depopulationagenda, #eugenetics, #repubicans, #auspol, #qanon, and #americafirst. The hashtags, as mentioned above, are related to Trump or against some figures who have publicly supported vaccines. Examples are #trump, #americafirst, or #faucifraud. These hashtags can also be found in the first community, where the percentage of both account types is similar. However, in this community, the number of bots is not higher than that of nonbots. In the third community, the number of nonbots is higher than bots. Most hashtags in this community mention COVID-19 (#coronaviruschallenge, #coronavirusbill, #coronaviruschina, and #coronavirusnewyork), but other hashtags such as #hoaxvirus, #tedconnnect, #freedomovefear, or #trumpisevil also appear.

5G

Regarding 5G, hashtags related to technology or news were the predominant ones in the case of nonbots, such as #techwar-#tradewar or #bbcaq-#itvnews. On the other hand, in the case of bots, the hashtags continue to mention geographical areas: #america-#china and #america-#lka. There are other hashtags with higher intensity, for example, #chinesecoronavirus-#democratshateamerica or #conspiracytheories-#technology. As can be seen in Table 2, the #china hashtag gets the highest PageRank value, followed by #pandemic and #wuhan. In addition, #china has 42 degrees of connectivity, doubling the value of the second, which is #pandemic with 27 connections. But above all, these values indicate the central place these hashtags take in the conversation. On the one hand, the high degree indicates they co-occur with many different hashtags. On the other hand, a high betweenness value indicates a central place in the network.

This time, the algorithm found 5 different communities of hashtags (Multimedia Appendix 1). The presence of bots is higher than nonbots in the first 3. The first is related to #tech, #bigdata, #cibersecurity, and so on. The second one is focused on #conspiracytheories, #digitalskynet, and #misinformation. The third is focused on China, with hashtags such as #batflu, #chinesevirus, and #huaweithis. The last 2 communities, where the level of nonbots is higher, are formed by varied hashtags. The fourth community is formed by hashtags such as #kag or #maga. The fifth one contains hashtags mentioning rumors or disinformation: #fakenews, #disinformation, and #democrathoax. In this community, it is worth mentioning the appearance of hashtags related to #blacklivesmatter, such as #racism, #blacklivesmatteraustralia, or #policebrutality.

UV

In this case, the appearance of technology-related hashtags (#ai and #healthtech) is even more noticeable, especially in the case of bots (Table 2). On the other hand, the most common hashtags are #batflu-#quarantine in the case of nonbots. Concerning the 6 communities we found (Multimedia Appendix 1), in the first 3, the number of nonbots is higher. The subject matter of these communities is related to politicians (#trump, #joebiden, and #berniesanders), technology (#artificialintelligence, #bioinformatics, and #machinelearning), or more specifically to technological innovation (#health, #innovation, #coronavirusnewyorkty, and #smartcities).

Discussion

Principal Findings

This study examined the use of hashtags by social bots on Twitter during the early stages of the COVID-19 pandemic. By analyzing the co-occurrence of hashtags, we were able to identify differences between accounts classified as bots and nonbots. We used Louvain communities to further classify these co-occurrences and found consistent differences in hashtag usage between the 2 groups. We used social network analysis

XSL•FO
RenderX

based on the co-occurrence of hashtags to take advantage of hashtags as key elements of online texts and understand how different users tag posts.

The analysis of hashtags provided several key insights into attitudes toward the COVID-19 pandemic and related behaviors. We consistently observed differences between bots and nonbots. In the case of bots, it was more common to find co-occurrences of hashtags related to political movements, particularly those on the right wing and related to Trump. This is consistent with findings in the literature showing a higher presence of conservatives in topics related to misinformation about COVID-19 pandemic [45].

In the conversation about vaccines, we observed that bots used hashtags related to fake news, such as #billgates and #china, more frequently. This analysis also identified specific uninformative hashtags (#ccpvirus and #chinesevirus) associated with anti-Asian sentiment [18]. Other hashtags expressed different opinions, such as criticism (#billgateisevil) or hate (#chinaliedpeopledied). It is worth noting that most of the tweets posted by nonbot users came from official accounts of institutions such as the World Health Organization, ministries of health, or entities related to public health. These messages focused on reporting on the evolution of the pandemic; the number of deaths; infection rates; and the health measures implemented, such as lockdowns and vaccination campaigns to contain the spread of the virus.

In our analysis of the conversation related to hydroxychloroquine, we identified 2 distinct communities of hashtags. One group was related to public health or medicine, while the other group was related to political movements and associated with Trump. Other studies have also found that Trump was involved in this conversation [46,47]. However, we also found that some of the hashtags in the conversation about hydroxychloroquine related to scientific facts. These differences suggest a highly polarized conversation with scientific arguments pitted against controversial political campaigns.

According to one of these studies [47], accounts with a higher impact on topics related to hydroxychloroquine disinformation were more likely to support President Trump. In addition, these types of content had a higher volume of tweets, longer duration in time, and greater echo. Our findings on the number of bots in these communities with politicized hashtags would partly explain the permanence over time and high echo values. Bots amplify these debates and increase the impact of the messages they disseminate [29,48,49]. However, our results also identify communities with anti–President Trump hashtags and higher numbers of bots. Liberals also engage in these conversations, although to a lesser extent than Conservatives [45].

These findings are extensible to topics such as the military or Bill Gates, where the conversation has been highly politicized and permeated with fake news. According to the results obtained, Trump occupied a leading role in the Twitter conversations during the period analyzed. This fact has also been noted in other previous works. Trump publicly supported the use of hydroxychloroquine and other drugs to combat the advance of the COVID-19 pandemic, with its corresponding impact on increased searches [50]. In addition, Bill Gates is often the protagonist in conspiracy theories [51].

Limitations and Strengths

There are several factors to consider when categorizing accounts as nonbot or bot. Botometer is backed by a large volume of research, but its effectiveness has been debated. It is important to remember that Botometer only provides a probability that an account is a bot, not a definitive classification. To get the most accurate results, it is recommended to compare probability distribution. However, in some cases it may be necessary to establish a binary classification for research purposes. In such cases, previous research has shown that using a cutoff value and comparing the results is a successful strategy [52].

It is important to consider the language constraint of this study. Only selecting tweets written in English may limit the focus to actors and events from English-speaking countries. In addition, no geographic limitations were placed on the collection of tweets, which allows for a larger volume of data but may also make it difficult to interpret results. It is also worth noting that the tweets analyzed in this study were from the early stages of the pandemic, and conversations and topics may have evolved over time.

Conclusion

Our analysis of hashtag usage on Twitter showed that there were differences in the patterns of use between bot and nonbot accounts. By grouping hashtags based on co-occurrence, we were able to identify distinct patterns in the usage of hashtags. On controversial or highly polarized issues, the hashtags used often pertained to the campaign or movement being promoted, with a significant portion related to Trump. In some cases, hashtags opposing these movements were also identified. On less polarized topics, hashtag usage was more diverse and included references to specific geographic locations or social groups. This analysis method can be useful in detecting hashtags that may be linked to fake news or misinformation, or in tracing the spread of such content on social media platforms.

Abstract

Background: Health misinformation, prevalent in social media, poses a significant threat to individuals, particularly those dealing with serious illnesses such as cancer. The current recommendations for users on how to avoid cancer misinformation are challenging because they require users to have research skills.

Objective: This study addresses this problem by identifying user-friendly characteristics of misinformation that could be easily observed by users to help them flag misinformation on social media.

Methods: Using a structured review of the literature on algorithmic misinformation detection across political, social, and computer science, we assembled linguistic characteristics associated with misinformation. We then collected datasets by mining X (previously known as Twitter) posts using keywords related to unproven cancer therapies and cancer center usernames. This search, coupled with manual labeling, allowed us to create a dataset with misinformation and 2 control datasets. We used natural language processing to model linguistic characteristics within these datasets. Two experiments with 2 control datasets used predictive modeling and Lasso regression to evaluate the effectiveness of linguistic characteristics in identifying misinformation.

Results: User-friendly linguistic characteristics were extracted from 88 papers. The short-listed characteristics did not yield optimal results in the first experiment but predicted misinformation with an accuracy of 73% in the second experiment, in which posts with misinformation were compared with posts from health care systems. The linguistic characteristics that consistently negatively predicted misinformation included tentative language, location, URLs, and hashtags, while numbers, absolute language, and certainty expressions consistently predicted misinformation positively.

Conclusions: This analysis resulted in user-friendly recommendations, such as exercising caution when encountering social media posts featuring unwavering assurances or specific numbers lacking references. Future studies should test the efficacy of the recommendations among information users.

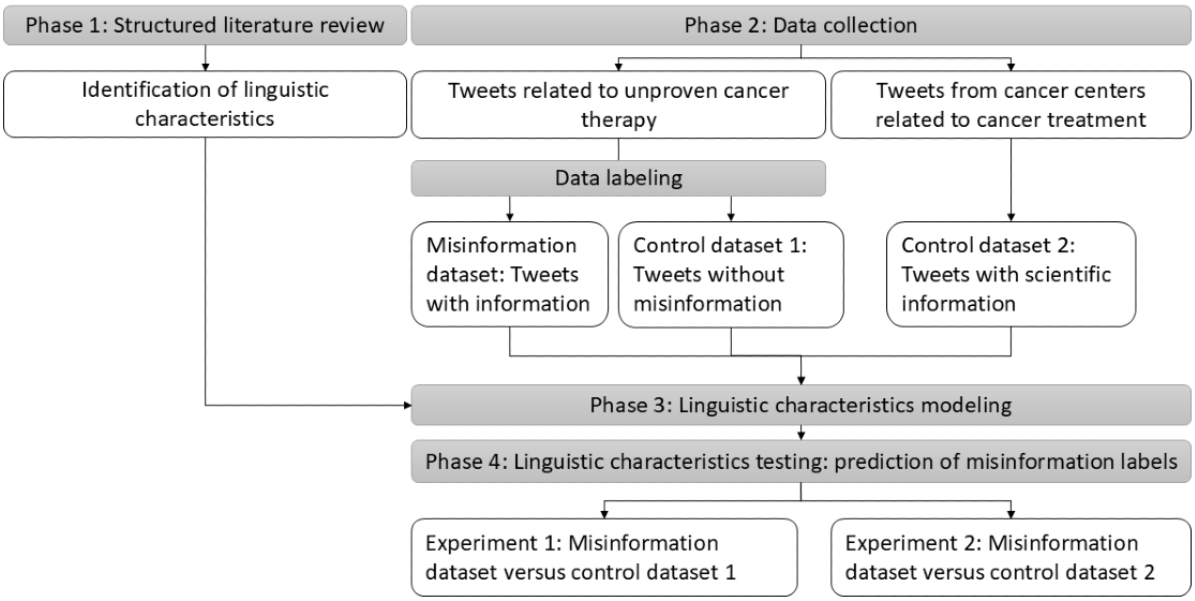
Introduction

Approximately 16% of people reported using social media to inform their medical decisions [1]. This percentage, based on estimates from the National Cancer Center, equates to 37 million adults in the United States. A recent systematic review estimated that up to 40% of health-related social media posts contain misinformation [2]. Misinformation could cause more harm to individuals with serious conditions such as cancer. Patients who believe in misinformation and use unproven therapies in parallel or in place of cancer treatment tend to be less adherent to evidence-based treatment [3-5]. Moreover, patients with cancer might choose to delay or reject evidence-based treatment and instead pursue unproven and potentially toxic therapies, which, for some patients, results in up to 2.5 times shorter life expectancy [6]. Approximately 30% of cancer-related social media posts on Facebook, Reddit, Pinterest, and X (previously known as Twitter) contain misinformation, and a staggering 77% of these posts have the potential to encourage patients to pursue futile and toxic therapies, resulting in physical, psychological, and logistical burdens [7]. Cancer misinformation persists across various cancer types and is more pervasive in more prevalent cancers. Across various social media platforms, two-thirds of the most shared posts about prostate cancer contain misinformation [8]. Researchers identified misinformation in 59% of posts related to breast cancer prevention and treatment [9] and 30% of posts related to gynecological cancer [10]. When surveyed, 70% of patients with cancer reported encountering misinformation about cancer on social media, with 71% believing that some of this misinformation was accurate [11].

There is a growing need to protect health information users from misinformation, especially those who are affected by serious conditions such as cancer. Multiple recommendations have been developed to assist individuals in their search for reliable health information [12-14]. However, many of the recommendations are complex, as they require individuals to possess a certain level of scientific knowledge and skills. For instance, recommendations frequently suggest taking steps such as identifying authors and their credentials, evaluating potential conflicts of interest, understanding funding sources, and assessing the original sources of scientific information. Considering the time and expertise required, expecting individuals to perform these tasks routinely is unrealistic. Moreover, these guidelines often fall short when it comes to addressing the challenges posed by social media platforms. Those who post may not disclose their real names or sources of findings, which makes some recommended steps not possible.

In this work, our goal is to identify user-friendly recommendations for addressing the high rate of misinformation on social media. We began by exploring literature on the algorithmic detection of misinformation. The algorithmic approach often involves the analysis of linguistic characteristics that differentiate between factual information and misinformation [15]. Linguistic characteristics describe a body of text in an abstract manner regardless of context and may include counts of words and word parts such as nouns, verbs, adjectives, and negations, as well as specific symbols such as URLs, hashtags, and question marks. An additional category of linguistic characteristics includes words associated with the psychological state of an author [16], which includes words related to emotions, expressions of certainty, tentativeness, insight, persuasion, and gratitude. To date, linguistic characteristics have been used by algorithms only. However, some of these characteristics are observable and could be used by individuals when they need to evaluate the credibility of the text. While individuals are unlikely to count words in social media posts regularly, they may routinely note other linguistic characteristics, such as emotions, URLs, and a strong degree of certainty. Linguistic characteristics have been shown to be effective in distinguishing misinformation from factual information across multiple contexts. However, it is unknown (1) whether the linguistic characteristics are effective in cancer-related context and (2) which subset of user-friendly linguistic characteristics could effectively distinguish misinformation. In this work, we identify the linguistic characteristics specific to the context of cancer. These characteristics will be recommended as guidelines for health information users when browsing social media.



Methods

Study Design

The main sequence of study procedures is illustrated in Figure 1 and includes (1) a structured literature review, in which we assemble linguistic characteristics that were used in algorithms for distinguishing factual information and misinformation (phase 1); (2) data collection, which encompasses assembling cancer-related posts using the X application programming interface (API) and labeling them as misinformation and non-misinformation (phase 2); (3) identification of the linguistic characteristics in collected datasets using natural language processing tools (phase 3); and (4) conducting predictive modeling analysis to evaluate the effectiveness of linguistic characteristics in distinguishing social media posts with cancer misinformation (phase 4).

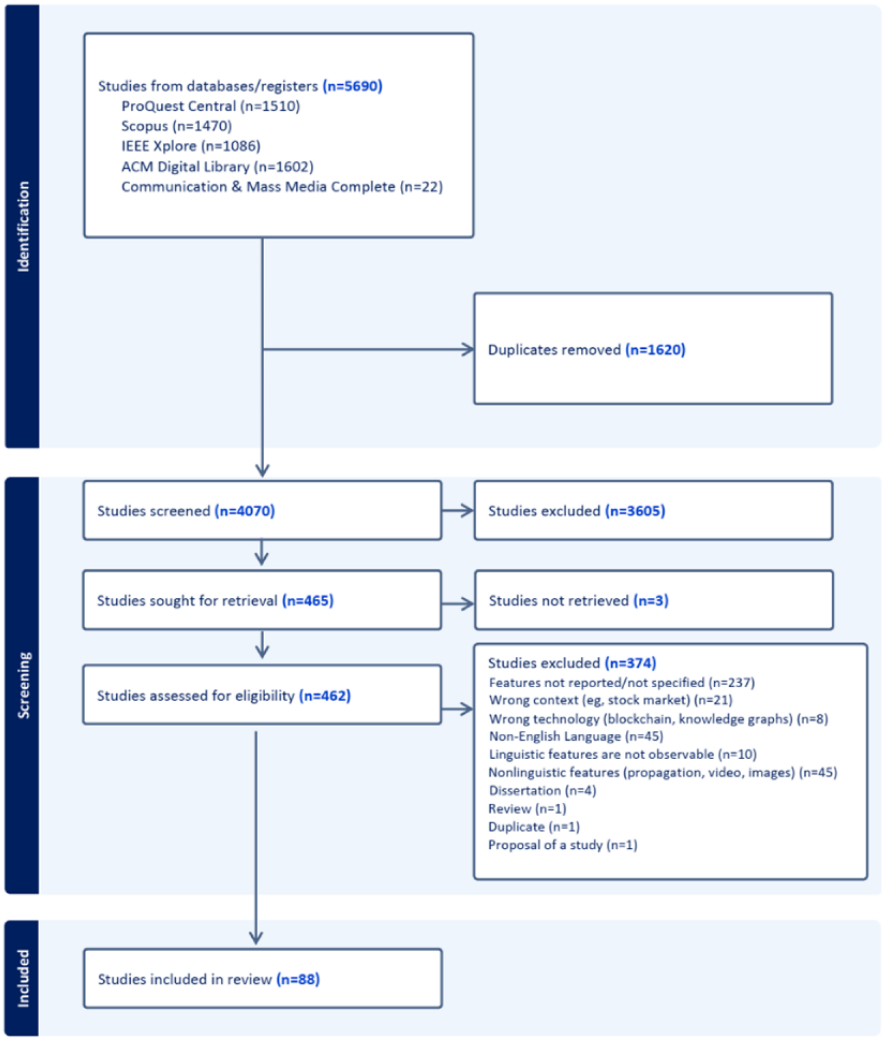
Figure 1. Summary of the study procedures.

Ethical Considerations

The study was institutional review board–approved by the University of North Carolina (IRB#21-2861). This was an analysis of publicly available data. As such, participants were not compensated and did not need to provide consent for the study, because the study did not involve any prospective data collection. To protect the confidentiality and anonymity of participants in this secondary data analysis, we reworded reported posts from X.



Structured Literature Review

To identify linguistic characteristics, we developed a literature review protocol that included the search strategy and keywords. This process was informed by a collaboration with a health sciences librarian (CBS), who suggested an initial set of keywords referenced in several relevant reviews [17-21]. She also created an expanded title, abstract, and keyword search strategies for each of the following concepts: (1) text as a unit of analysis, (2) misinformation, (3) algorithms, (4) internet, and (5) linguistic features or characteristics. After the search was peer reviewed by a second health sciences librarian (CB), 5 databases were searched: ProQuest Central (ProQuest), which includes the arXiv repository; Scopus (Elsevier); IEEE Xplore (Institute of Electrical and Electronics Engineers); ACM Digital Library (Association for Computing Machinery); and Communication & Mass Media Complete (EBSCOhost). The keywords and search strategies are reported in Multimedia Appendix 1. Results were limited to citations published between January 2012 and December 2022. Within databases, results were limited to journal papers, conference proceedings, working papers, and book chapters.

Two reviewers (IF and DB) independently coded titles and abstracts in Covidence software (Veritas Health Innovation) [22] and resolved conflict in codes during research meetings. Papers were included if they focused on detecting misinformation and contained a “Methods” section describing an approach for algorithmically detecting misinformation (eg, reviews and viewpoints were excluded). Examples of the algorithms included supervised and semisupervised machine learning (eg, Bidirectional Encoder Representations from Transformers [BERT] classification) that was built on linguistic characteristics. Papers were excluded if they did not report specific linguistic characteristics, focused on misinformation in any language other than English, or used human coding but not algorithms. The detailed inclusion-exclusion criteria and PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram are reported in Figure 2.

XSL•FO
RenderX

Figure 2. Flowchart of paper identification and extraction.

Identification of Linguistic Characteristics

Upon identifying eligible papers, 2 team members (IF and DB) reviewed the full text and extracted the linguistic characteristics. Around 11% (10/90) of papers underwent double-coding. After reviewers reached an agreement, we continued with single coding. The linguistic characteristics were extracted based on the following criteria: observability, applicability, and generalizability. The observability criterion was related to whether readers could easily observe the linguistic characteristics within the text; for example, positive emotions could be easily observed while morale or cognitive language styles may be difficult to distinguish. The applicability criterion distinguished linguistic characteristics that readers could easily apply while reading the text. For instance, common characteristics such as the number of words required substantial effort from readers to evaluate and, therefore, were deemed nonapplicable. In contrast, readers could easily use citations and hashtags in their post evaluations as the mere presence of these characteristics was determined to be helpful in identifying misinformation. The third criterion, generalizability, was chosen to ensure that linguistic characteristics were not related to a specific context but could be applied across various contexts. Thus, characteristics that were based on specific words such as "COVID-19," or "cure" were excluded.

Data Collection: Unproven Therapy

Overview

To test how extracted linguistic characteristics could distinguish social media posts from misinformation and factual information, we collected social media posts from X. Misinformation was operationalized here *as information that promoted cancer treatment that was known as ineffective or information that suggested cancer causes not supported by current scientific evidence* [23]. This definition focused our investigation on misinformation that could be harmful to patients with cancer or cancer survivors. Based on this operationalization, we searched existing resources that summarized unproven cancer therapy, such as "List of unproven cancer therapy" [24], a list of "Illegally sold cancer drugs" [25], and previous literature [23,26]. We extracted keywords and constructed 176 queries associated with unproven cancer treatments (Multimedia Appendix 2). Using these queries, we randomly selected up to 500 posts per query from social media. We used R software (R Foundation for Statistical Computing) to access the Academic X API. The data were manually evaluated to determine their relevance to the cancer context and unproven therapies. Queries

XSL•FO
RenderX

were edited to ensure relevance. Upon corrections, the data collection was implemented on a schedule every other week between July 2022 and August 2023. After data collection was completed, the duplicate posts were removed.

Data Labeling

To distinguish posts with misinformation from other discussions, 2 reviewers (IF and CR) double-coded a randomly chosen subset of 1064 posts, achieving an acceptable interrater agreement of 0.68 measured with Krippendorff a [27]. Since the agreement was rather on a lower bound, we followed the current recommendations [28] and resolved disagreements between coders during research meetings, reaching consensus case by case. The initial criterion for coding misinformation was developed deductively based on the definition of misinformation used in this study. A post was coded as containing misinformation if it promoted an unproven therapy as a cancer-directed treatment. For example, a post claiming that an alkaline diet can eliminate cancer would be classified as misinformation: "Cure for cancer is an alkaline diet and lots of alkaline water." As reviewers worked with the data, they developed additional criteria based on observed patterns. Specifically, posts were labeled as containing misinformation if they discussed unproven approaches to prevent cancer, for example, "Pygeum Bark is nature's defense against prostate cancer." Furthermore, if a post contained a combination of factual and false information it was labeled as "misinformation."

Posts that were labeled as non-misinformation fell into 4 distinct categories. First, posts mentioned complementary and alternative medicine but did not promote it as a cancer treatment, for example, "Acupuncture and acupressure seem to be helpful in reducing pain and anxiety in patients having surgery." Second, posts that used sarcasm and actively debunked misinformation related to cancer were in the non-misinformation category, for example, "If what you stated is true, then Gerson treatment for cancer is false." The third category included posts that discussed complementary and alternative therapies but not in the context of promotion of cancer treatment, for instance, "Grapes can help protect you from the sun! Who knew?" Finally, posts that presented information with ambiguity, lack of clarity, or insufficient context were categorized as non-misinformation, for instance, "As a pancreatic cancer patient providing myself with all the additional holistic care practices made all the difference." The author did not specify whether his symptoms were alleviated or cancer progression was slowed down because of holistic practices. Therefore, the post was coded as non-misinformation.

Once a subset of the database was labeled by 2 reviewers (IF and RC), we applied an algorithm to populate labels to the entire database. We worked with BERT [29], a machine learning model for natural language processing. The BERT model was chosen because it (1) worked well with short, informal text [30]; (2) was shown to be applicable to medical text extracted from X [31]; and (3) was successfully used in previous research to identify misinformation on X [32]. The BERT model was implemented with the programming language Python (Python Software Foundation). The manually prelabeled subset served as training data for the BERT model. Such semisupervised approaches are commonly used in similar classification tasks [33]. After training, BERT used its understanding of the language and context learned from the large corpus it was originally trained on and the specific examples from the manually prelabeled dataset. BERT predicted labels for each post in the rest of the data (unlabeled dataset), determining whether each was likely to contain misinformation or not based on the patterns and features it learned from the manually coded dataset.

After BERT algorithm assigned labels to the posts, a researcher (IF), blinded to the model's results, manually coded a random subset of the posts (n=960) using the same "misinformation" and "non-misinformation" labels, adhering to the same criteria that were used to prelabel the data. When compared with manual coding, the algorithm identified misinformation with an accuracy of 83%, with a higher 86% specificity, and a slightly lower sensitivity of 82%. Upon labeling, 2 datasets were created and used in the first experiment: the misinformation dataset included only posts with misinformation, and control BERT dataset 1 included only posts with non-misinformation (Figure 1).

Data Collection: Posts From Cancer Centers

Following the definition of misinformation as "information not supported by scientific evidence or expert consensus" [34] and the definition used for this research, we assumed that posts originating from cancer centers reflect scientific evidence and expert consensus. To collect posts with factual information, we retrieved X data posted by cancer centers. Cancer centers often shared internal announcements and organizational news on X. To make posts comparable between the dataset with misinformation and control datasets, we used the keywords "cancer," "treatment," "chemotherapy," "healing," and other words related to treating cancer or controlling cancer progress. With the help of R software, we sampled 300 posts per cancer center between June 2011 and November 2022. A researcher (IF) manually checked randomly chosen (n=100) posts. As expected, no misinformation was found in the posts originating from cancer centers. The dataset, therefore, was assumed to consist of non-misinformation posts from cancer centers and was designated as control dataset 2, which was used in the second experiment alongside the misinformation dataset.

Linguistic Characteristics Modeling

Upon data collection and labeling, we used algorithmic approaches to model linguistic characteristics. First, we used an automated text search using regular expressions in Python [35] to capture digital numbers, hashtags, and URLs in the text.

Second, we used the Linguistic Inquiry and Word Count (LIWC) software [36]. LIWC calculates the proportion of the words in the posts associated with distinct psychological dimensions [37]. In this study, LIWC identified when authors of posts used certain, absolute, or tentative language.

Third, we leveraged the natural language processing tool, Name Entity Recognition [38], which was trained on human-labeled datasets to extract names from unstructured text. Using Name Entity Recognition, we were able to identify which posts contained personal names, organizational names, or locations identified from text.

XSL•FO
RenderX

Fourth, we experimented with several models for sentiment analysis and identified the DistilBERT algorithm as an optimal approach for its accuracy in handling health-related X data [39]. DistilBERT is a black-box algorithm that is trained on a large corpus of data and is based on multiple deep stack layers. The DistilBERT algorithm identified positive, negative, and neutral tones present in the posts. To evaluate the algorithm's performance, we manually labeled 300 posts across the databases. On average, the DistilBERT algorithm achieved an 83% accuracy (82% for misinformation and 84% for the control database) in detecting the emotional tone within the posts.

Linguistic Characteristics Testing: Prediction of Misinformation Labels

Identified linguistic characteristics were used in an algorithm to test whether these could distinguish misinformation in posts. As shown in Figure 1, we conducted 2 experiments using *tidymodels* package in R software [40]. Using linguistic characteristics as predictors, we forecast the "misinformation" and "non-misinformation" labels in the datasets semimanually coded by researchers and BERT classification algorithm. Data were split 60:40 to enable evaluation of the predictive power of the model and reported the accuracy as a ratio of correctly classified posts to the total number of posts. We also reported area under the curve (AUC), which accounted for both false-positive and false-negative predictions. AUC value ranged from 0 to 1, where 0.5 indicated that the model performs no better than a random chance, and 1 was a perfect prediction. The model was built on the basis of Lasso ("Least Absolute Shrinkage and Selection Operator") regression, which allowed variable selection by shrinking the coefficients of less important predictors to zero [41]. Bootstrapping procedure was applied to optimize and stabilize the selection of variables [42]. Lasso was chosen to address multicollinearity and overfitting issues in the regression model. More importantly, Lasso regression helped identify a set of linguistic characteristics that effectively distinguished posts containing misinformation. To evaluate the significance of specific linguistic characteristics, we computed importance scores, with higher scores indicating greater relevance in distinguishing posts containing misinformation. Importance scores, a common measure in predictive modeling, indicates to what extent individual predictors contribute to the overall model performance. The assessment involves permutating the characteristic values through shuffling and measuring the subsequent decline in model performance, effectively revealing the critical factors influencing predictions. Finally, we conducted a permutation statistical test (with 1000 permutations) to determine whether models with linguistic characteristics significantly outperformed random chance.

Results

Structured Literature Review

A total of 5677 citations were initially identified across all databases. After removing 1598 duplicates, we screened 4070 unique citations in Covidence. Subsequently, 3605 were excluded during the title and abstract review phase, leaving 464 papers for full-text review. Ultimately, we extracted linguistic characteristics from 88 full-text papers. These papers featured algorithmic approaches for identifying misinformation through automated text analysis, spanning various contexts, including politics, social issues, and computer science. Exclusion reasons are detailed in Figure 2, and additional information about the included papers can be found in Multimedia Appendix 3.

Identified Linguistic Characteristics

The extracted linguistic characteristics and corresponding literature are detailed in Table 1. Representative examples that contain each linguistic characteristic were chosen by selecting posts from the misinformation dataset. We used results from linguistic characteristic modeling to identify such posts. The first category of characteristics pertains to the sentiment and emotional expression in the text and includes positive, negative emotions, and neutral sentiments (absence of either). Some papers delved into more nuanced emotions such as anger, fear, surprise, and others. We excluded these emotions due to the potential difficulty for readers to detect nuanced emotions reliably in the text.

The next category comprises linguistic characteristics that pertain to psychological concepts. It is worth noting that some psychological concepts consist of a combination of linguistic characteristics, such as social processes including references to family, friends, other people, and verbs indicating interactions. Although algorithms frequently use such combinations, we decided to exclude the following psychological concepts that consisted of combinations of linguistic characteristics such as cognitive, perceptual, social processes, and morality or deception. The rationale behind this exclusion is that users are unlikely able to observe and combine linguistic characteristics for evaluations of the posts. We also excluded characteristics mentioned in fewer than 4 studies, such as gratitude, insight, causation, and persuasion. Following our 3 criteria, we included negations, tentativeness, profanity (as a proxy of informality), and words associated with absolutes and certainty.

Other categories that met our inclusion criteria were linguistic characteristics such as names of individuals, locations, and organizations, as well as categories related to the presence of URLs, hashtags, personal pronouns, and numbers. Readers can identify these characteristics without additional efforts (observability criterion) and use them for evaluation of the text (applicability) because the presence of these characteristics in social media has historically been a distinguishable factor in detecting misinformation. Furthermore, these characteristics were not context-dependent and, therefore, satisfy the generalizability criterion.

Table 1. Linguistic characteristics and examples of misinformation.

Characteristics	Examples of linguistic characteristics and posts with misinformation[a]	Studies using characteristics for misinformation detection
Sentiment[b]		[43-93]
Negative emotions	• Chemo is costly and very painful. It seems to worsen illness and hasten life's end. • Sad this happened, to overcome cancer, consider utilizing cannabis oil in combination with vitamin B17. • Feeling frustrated that insurance doesn't cover certain treatments I believe in. Wish there were more options beyond the conventional cut, burn, and poison approach.	
Positive emotions	• Cure for cancer that works holistically, Vitamin B17, very good! • Please do some heavy doses of medical organic marijuana if possible let it eat that cancer. Wishing you healing and joy and comfort. • Wonderful treatment! Discover the incredible benefits of ProstateRelax, a natural herbal treatment for prostate cancer. ProstateRelax effectively treats and prevents the progression of prostate cancer.	
Neutral emotions	• Anyone with cancer. Check your body's pH level. Drink alkaline water, eat alkaline foods, and avoid acidic sugary treats and dairy. • Cancer cells thrive in low oxygen environments. B17, found in apricot seeds, can help. • Antineoplastons, a protein suppressed by cancer, could hold the key to a potential cure.	
Psycholinguistic		
Negation	• Unlock the potential of Acupuncture to modulate immunity and create an environment where cancer cannot thrive. Discover the holistic power of this ancient practice in bolstering your body's defenses against cancer. • I wonder why aren't we utilizing hyperbaric chambers for Cancer? Ask your doctor about the incredible potential of pure oxygen in rejuvenating and generating new cells to combat this disease. • Don't consume sugar (as cancer thrives on it), minimize or eliminate carb-rich foods like bread and pasta, and limit alcohol intake. Embrace the power of fasting to allow your body to heal itself.	[46,49,53,70,79,81,94-96]
Tentativeness	• 3 women with similar cancer, undergoing comparable treatments—2 passed away, but 1 is thriving Possible factor? She incorporated mistletoe & other non-pharma medicines into her regimen. • Concerns about [standard treatment] as a cancer solution persist, with claims of it being a harmful creation backed by influential medical forces. If it truly worked, wouldn't it have been banned long ago like Laetrile? • Listen or not: Vitamin B17, found in Apricot seeds and sold online as a "health supplement," has caught my attention as a potential cancer cure.	[49,51,59,61,62,66,81,94,96-100]
Absolute language or certainty	• I take sea buckthorn pills! They are an absolute lifesaver. • Vitamin B17 has definitely prevented my cancer from spreading. It's been a while, and there has been no growth. • During my time in a chemo clinic, alternative treatments were never allowed to be discussed or promoted. I left and started studying herbal medicine.	[43,51,59,61,94,97-101]
Profanity	• Create an alkaline environment that cancer can't thrive in! Incorporate herbs, vitamins, and minerals to support your healing journey. You are going to heal and beat that s*** • Go to a poor country and you get real tea with real ginger. Go to a rich country and you will get chemical b**** that will give you cancer • It damages healthy cells, no surefire cancer cure. It's like a c*** shoot for survival & recurrence. But I choose a different path: starving cancerous cells with therapeutic fasting & lifestyle shifts.	[48,57,62,63,66,69,81,89,96,98,102]

[a]All posts were paraphrased to protect the author's anonymity.

[b]In sentiment analysis, emotions are identified by a "black box" model (DistilBERT). While we report here examples and highlight "negative/positive" words in the sentence, we must acknowledge that the algorithm may or may not use these words for detecting emotions.

Collected Data From X

We collected a total of 45,791 posts related to unproven cancer therapies. Among these, 13,046 posts were labeled as misinformation (forming the misinformation dataset), while 32,745 posts were categorized as non-misinformation (comprising control dataset 1). Furthermore, we gathered 6782 posts from the profiles of comprehensive cancer centers, which were used as control dataset 2, as shown in Figure 1. The content description of both the misinformation dataset and the control dataset 1 is shown in Table 2. To illustrate the dataset in this study, we categorized the X posts into 9 distinct categories. The examples of the posts with misinformation are shown in Table 1.

Table 2. Relevant prevalence of therapy categories within posts about unproven cancer therapy.

Categories of therapies	Total posts, n	Posts with misinformation, n (%)[a]	Examples of unproven cancer therapy
Diet based	5179	3069 (59)	Antioxidant, fasting, and alkaline diet
Alternative health system	7036	2250 (32)	Herbal therapy and ayurveda

Linguistic Characteristics Testing: Prediction of Misinformation Labels

As shown in Table 3, experiment 1 demonstrated that linguistic characteristics predicted misinformation with 60% accuracy. In experiment 2, they exhibited even stronger predictive power, achieving an accuracy of 77%. The importance scores for each linguistic characteristic are shown in Table 4.

Next, we selected linguistic characteristics with an impact score 0.05 and consistent predictive performance across experiments 1 and 2. These short-listed characteristics underwent further testing within the same experiments. In experiment 1, the short-listed characteristics achieved an accuracy rate of 50%, which did not significantly differ from random chance (P>.90). However, in experiment 2, these characteristics predicted misinformation with an accuracy rate of 73% and an AUC of 83. This performance was significantly better than random chance (McNemar $^2_1$=5.7 ×10^7; P<.001). The importance scores for the short-listed characteristics are shown in Table 4. For a more detailed breakdown of the importance scores, we have summarized the percentage of posts containing these short-listed characteristics by dataset in Table 4 and the complete list in Multimedia Appendix 4.

Table 3. Lasso regression performance.

Name of the dataset	Total posts, n	Posts with misinformation, n	Accuracy, %

Discussion

Principal Findings

We have identified linguistic characteristics that can help people affected by cancer detect cancer misinformation on social media platforms such as X. Linguistic characteristics that were *likely* to be present in posts with misinformation were related to certain, absolute language, and numbers. Certain language included phrases that reflected a "degree of bravado" or "boasting of certainty." Examples of certain languages could be "I really believe," "it is definitely helpful," and similar others [36]. The absolute language referred to phrases that reflect black-and-white thinking and included words such as "none," "all," "never," and others [36]. The number category encompassed any information reported with digits such as percentages, count of any units, years, and priorities. Notably, all 3 linguistic characteristics could be united under the umbrella of definite, confident language. Linguistic characteristics that were *unlikely* to be present in posts with misinformation encompassed URLs, hashtags, and location mentions. Each of these attributes could be considered as a form of citation or reference. URLs offered direct links to the original source or further information, hashtags connected posts to broader relevant discussions, while locations mentioned in posts provided context and a sense of origin to the information shared. Our findings are consistent with some of the suggestions provided by previous guidelines for identifying misinformation. For instance, the Food and Drug Administration recommends being vigilant if patients read confident statements such as a drug definitely "cures cancer" or "guarantees results" [124]. Other guidelines encouraged users to search for references and original sources of health-related information [12-14].

While consistent with previous recommendations, our findings make a unique contribution. Previous work has based the guidelines on theoretical assumptions, while our study is one of the first to provide some empirical evidence based on a large dataset to support the recommendations for users. Another contribution is that we outlined ineffective linguistic characteristics for detecting cancer misinformation. Despite a substantial body of research showing that social media posts with sentiments predicted fake news, we did not find these relationships. A potential explanation could be the algorithm's limited efficiency in identifying emotions within cancer-related contexts. Furthermore, it is possible that authors express a limited range of emotions in cancer-related conversations, typically negative emotions toward cancer and both positive and negative emotions toward various treatments, including those that are unproven. These emotions may vary little across posts containing valid and nonvalid information, making emotions an unreliable factor for distinguishing misinformation.

Our work accumulates knowledge about misinformation detection from the literature covering a wide range of contexts—including political, social, and computer science—and translates this knowledge to the cancer context. The findings highlighted promising avenues for future research and could expedite the development of automated and augmented methods for identifying and verifying cancer-related misinformation on social media platforms. Finally, the robust labeled datasets developed by our research team are available to other researchers upon request to the corresponding author, thereby further supporting research on misinformation within the context of cancer and social media.

In practice, our work is at the forefront of customizing recommendations and contextualizing them for social network users. Our exploratory findings suggest a promising direction for studying linguistic characteristics that information users might apply when making quick judgments while scrolling through X feeds. Empowering users to stay vigilant in their initial evaluations could help reduce the spread of misinformation and the formation of erroneous beliefs. This is a crucial area for future research, which should explore how these findings apply in different cancer-related contexts and across various social networks.

Limitations

All the studies included in our analysis exclusively originate from peer-reviewed journals and conference proceedings; however, we must exercise caution when considering the potential for publication bias. Furthermore, in accordance with our selection criteria for linguistic characteristics, we included

XSL•FO
RenderX

only those papers that focused on text and excluded other forms of social media content, such as videos and images. We recommend that future research comprehensively explore social media, including multimedia content, as it could potentially provide additional insights for user-friendly recommendations.

In selecting linguistic characteristics, we prioritized observability, applicability, and generalizability. However, alternative criteria may be considered when users are open to a more thorough exploration of a post's validity. For example, future research should explore the use of metadata, link content analysis, and hashtag meanings. As misinformation evolves and its authors adjust to societal changes, the linguistic characteristics that identify misinformation may also shift. A longitudinal analysis is necessary to understand how linguistic characteristics perform in predicting misinformation over time.

Algorithms used in our analysis operate with a certain level of accuracy. Specifically, the accuracy of label identification in the dataset reached 83%, indicating that approximately 17% of posts were labeled incorrectly. This means that in experiment 1 some proportion of misinformation is included in the non-misinformation group and vice versa, making further exploration less accurate in experiment 1. This degree of uncertainty is common in algorithmic performance. Therefore, it is important to interpret our results in light of the inherent imperfections in algorithmic performance.

Furthermore, we encountered that the short-listed linguistic characteristics did not significantly outperform random chance in identifying misinformation in experiment 1. This outcome underscores a potential boundary condition of the effectiveness of the linguistic characteristics. Notably, experiment 1 encompassed more homogeneous data in contrast to experiment 2. Based on these findings, it becomes plausible to speculate that linguistic characteristics might provide limited help when a reader assesses posts within a closely knit community.

In experiment 2, the control dataset 2 consisted of posts shared by cancer centers and was compared with the misinformation dataset comprising random posts. To address this limitation, we collected posts from cancer centers that contain words related to cancer therapies. This step was taken to ensure a similar context of discussion as the posts with unproven therapy. Next, we exclude linguistic characteristics that are likely displayed differences between datasets due to the distinct nature of the information within control dataset 2. For example, linguistic traits such as "the use of profanity" or "first-person pronouns" were discarded. Furthermore, we decided to focus our analysis solely on the text within the posts and omitted other accompanying metainformation that users might observe, such as the user's name, location of the author, and posting time. This approach allowed us to assume that posts shared by cancer centers might be perceived more broadly, for instance, as posts shared by researchers, physicians, administrators, and patient advocates. Because of these measures, we anticipate that the linguistic characteristics identified in this research may help differentiate between health misinformation and factual posts on social media, irrespective of their sources. Despite our precautionary measures, we cannot fully guarantee that identified linguistics characteristics certainly distinguish between posts with misinformation and non-misinformation versus posts produced by the general public and posts by health experts from health care systems. However, there are factors that support the first conclusion more than the second. First, our findings are consistent with the previous theoretical and practical recommendations for identifying misinformation [12-14]. Second, the associated with misinformation linguistic characteristics, such as numbers and assertive language, are expected to be used by health experts. For instance, providers use numbers more confidently than the general public [125]. Professional guidelines for health providers encourage them to use numbers over verbal descriptions [126] as well as the use of assertive language in communication with patients [127,128]. Yet, our study associated these characteristics with misinformation shared by the general public on social media, which suggests that we might be finding more than just a mere distinction between the general public language and the health professional language. One study in and of itself is not yet a comprehensive body of evidence. Our findings will need to be validated and built upon via additional studies—including those that use posts from other types of entities and comparison groups.

Finally, our data were collected only on a single social network X. Many characteristics and customs of X are transferable to other social networks and our recommendations are likely to go beyond application on X, as demonstrated by the consistency of our recommendations with the recommendations of other researchers [12-14]. Given this limitation, our results need to be generalized cautiously, and further similar research is needed for different platforms (eg, Facebook, Pinterest, etc).

Conclusions

Our structured review synthesized knowledge from studies that used algorithmic approaches for text analysis to detect misinformation in social media. From this literature, we identified user-friendly linguistic characteristics that can assist individuals in distinguishing misinformation when they seek health-related information on social media. The linguistic characteristics, such as certainty, absolute language, and numbers, were positively associated with misinformation, while characteristics such as URLs, hashtags, and location mentions were negatively predictive of misinformation. Based on these findings, we suggested that users should be cautious of social media posts containing confident promises or specific numbers without proper references to the original information. According to our analysis, we expect that this approach will allow users to filter out two-thirds of posts with cancer-related misinformation. Yet, before drawing a definitive conclusion, further testing with different datasets is required.

Abstract

Background: During the COVID-19 pandemic, many people sought information from websites and social media. Understanding the extent to which these sources were trusted is important in relation to health communication.

Objective: This study aims to identify the key factors influencing UK citizens' trust and intention to act on advice about COVID-19 found via digital resources and to test whether an existing model of trust in eHealth provided a good fit for COVID-19–related information seeking online. We also wished to identify any differences between the evaluation of general information and information relating specifically to COVID-19 vaccines.

Methods: In total, 525 people completed an online survey in January 2022 encompassing a general web trust questionnaire, measures of information corroboration, coping perceptions, and intention to act. Data were analyzed using principal component analysis and structural equation modeling. The evaluation responses of general information and COVID-19 vaccine information were also compared.

Results: The principal component analysis revealed 5 trust factors: (1) credibility and impartiality, (2) familiarity, (3) privacy, (4) usability, and (5) personal experiences. In the final structural equation modeling model, trust had a significant direct effect on intention to act (β=.65; *P*<.001). Of the trust factors, credibility and impartiality had a significant positive direct effect on trust (β=.82; *P*<.001). People searching for vaccination information felt less at risk, less anxious, and more optimistic after reading the information. We noted that most people sought information from "official" sources. Finally, in the context of COVID-19, "credibility and impartiality" remain a key predictor of trust in eHealth resources, but in comparison with previous models of trust in online health information, checking and corroborating information did not form a significant part of trust evaluations.

Conclusions: In times of uncertainty, when faced with a global emergent health concern, people place their trust in familiar websites and rely on the perceived credibility and impartiality of those digital sources above other trust factors.

Introduction

Background

The COVID-19 pandemic understandably led to an increase in "official" sources of information and advice from politicians, public health officials, clinicians, and scientists. This public-facing information was communicated via the mainstream press, through live-streamed press briefings, and online. However, "unofficial" sources of information were also circulated, primarily via social media. For individuals, access to good quality information during the pandemic was critical,

XSL•FO
RenderX

not least because official messaging was constantly being updated in relation to recommended or mandated behaviors such as social distancing, mask-wearing, and self-isolation.

During this time, many people sought their information online [1] through websites, social media, and mobile apps. People looked for information on the signs and symptoms of the virus, measures to avoid catching and spreading the virus, self-care once infected, and vaccination information. In addition to health advice, people also sought related information on rules and guidance regarding self-isolating, masks, and social distancing.

Accurate and appropriate health communication is an important tool in tackling any pandemic and it can directly influence individuals' affective and behavioral responses to a crisis [2]. In relation to the COVID-19 pandemic, studies have shown that access to a larger and more diverse set of information sources led to increased worry [1,3] and greater confusion, in part because of the infodemic of misinformation and rumors that were promoted about the pandemic [4]. The UK Government's approach to tackling COVID-19 relied upon broad public trust, but issues with inconsistent and unclear messaging, as well as general political mistrust, were apparent [5]. In short, it sometimes became difficult for people to know who to trust in relation to taking appropriate actions to reduce the spread of COVID-19 and minimize personal risk.

Against this backdrop, the aim of this study was to understand more about the digital resources people in the United Kingdom used for COVID-19–related information and the extent to which they trusted these resources. Although we know that online health formed a key source of information for many people during the pandemic, we do not know how people evaluated these digital sources and what factors were important in trusting the information, the source, and ultimately deciding whether or not to act on the advice given. We also wished to test whether an existing model of trust in eHealth provided a good fit for COVID-19–related information seeking online. We begin by briefly reviewing the literature on trust and eHealth before introducing the COVID-19 context and outlining the study objectives.

Trust in Online Health Information

Over the last 20 years, research has consistently pointed to the importance of both the design and the content of websites in terms of establishing trustworthiness [6,7]. Commonly reported indicators of trust and credibility include site owners or sponsors; consensus among multiple sources; characteristics of writing and language; advertisements; content authorship; and interface design [8]. Related studies have looked at the quality of web-based health information and have highlighted navigability, aesthetics, and ease of understanding as important factors [9]. As digital resources for health have developed and diversified, we have seen a move away from government and medically driven sources towards more charity and patient-led sites [10] and the use of social media [11,12] meaning that shared patient experience has also become a critical factor in determining trust and appropriateness of online advice [13].

Despite concerns about the quality and reliability of some digital sources [14], they are often well-used and well-liked. Interestingly, they are not necessarily trusted and the advice they contain is not always acted upon. In part, this may relate to a dislike in the United Kingdom for commercial funding models underpinning health websites [10]. A recent model of trust in eHealth [15] found that credibility and impartiality are the key predictors of trust in eHealth websites and noted that websites containing patients' experiences can have a positive impact on trust but only if those sources have been checked against other sources first. The authors also noted that the need to corroborate digital information sources may be reduced in cases where there is strong familiarity with a well-used website.

COVID-19 Context

The COVID-19 pandemic led to a global surge in information seeking online in relation to the spread of the virus, best means of protection, access to health care, local rules and guidance, and, subsequently, information about COVID-19 vaccines, tracing apps and COVID-19 passports [16]. While official sources moved quickly to try and fill these information gaps, social media platforms provided a space for information and misinformation to circulate widely [17]. Conspiracy theories and rumors in relation to the virus and the vaccine were prevalent online as was poor-quality information [18-20]. The unique situation increased attention on governments as a source of information however historically government and official health sources have been subject to mistrust and their health messages resisted especially concerning vaccinations for example in the case of the Measles Mumps Rubella vaccination and the H1N1 (swine flu) vaccination program [21,22]. In these cases, trust in nonofficial information sources and the media is often higher.

United Kingdom Context

In response to the global pandemic, the UK prime minister announced a national lockdown on March 23rd, 2023 [23]. Daily press briefings followed, led by politicians and National Health Service (NHS) leaders providing coordinated information on COVID-19 legislation and guidance, health advice, and subsequently the vaccine rollout.

Survey data indicates there was a slight increase in political trust in the United Kingdom as the lockdown commenced [24] and most people supported the government enforcement of behavior in the early months [5] with positive views on government decision-making related to response transparency. Although people looked to government and health leaders for information and guidance these officials were not immune from criticism. Politicians and advisors often found themselves at the center of news stories that challenged perceptions of trust [24], and of privacy and security, for example in relation to the rollout of contact tracing apps [25] and COVID-19 passports. Low trust in scientists and medics was also associated with COVID-19 vaccine hesitancy [26].

The sudden onset of COVID-19 and its impact not just on UK citizens but worldwide highlighted the public's need for information. Understanding how individuals sought information from digital sources and whether they trusted this information is the focus of this study. Note that this distinct aim is different from many of the studies of information-seeking behavior during

XSL•FO
RenderX

the pandemic that were more focused on the motives that drive online interrogation. Typically, these searches adopted the Risk Information Seeking and Processing model [27] which sees risk information seeking as driven by factors such as information insufficiency, subjective norms, and relevant channel beliefs. Although the Risk Information Seeking and Processing model has been used effectively to model information-seeking behaviors in relation to COVID-19 [28,29] it says relatively little about the extent to which people decide whether to trust the information they are exposed to.

Other studies have examined overall levels of trust in traditional information sources concerning COVID-19 by comparing television, radio, and newspapers with websites [30] but to our knowledge, this is the first study that examines trust and the antecedents of trust in different digital resources in relation to COVID-19. Focusing on the antecedents of trust at this time alongside individuals' behavioral and attitudinal responses to the information they found is key for our future understanding of trusted health communication during health emergencies.

Rationale for This Study

The revised model of trust in eHealth [15] indicates a number of antecedents for trust in online health information and advice and for intention to act on that advice. This study builds upon that work by asking whether existing trust models are a good fit for COVID-19 information-seeking online. The uncertainty provided by the COVID-19 pandemic provides a unique opportunity to examine how people search for, evaluate, and make trust decisions about health information and advice.

The COVID-19 pandemic provides an opportunity to examine in more depth the type of health information seeking that has been taking place. As described previously, people's information needs vary including information on symptoms and symptom management, self-isolation, and vaccination. Vaccination in particular presents a unique opportunity to explore health information seeking within the context of heightened uncertainty and self-reported behavioral outcomes.

It may be that the global nature of the pandemic and people's desire for information exchange fueled social media sources of health information and increased visibility of patient experiences. On the other hand, information corroboration is effortful, and in times of heightened stress and uncertainty, it may not be appropriate or lead to better coping outcomes. Relying on a single source of information may be more straightforward but trust in government or health professionals may impact trust perceptions around such information sources.

Therefore, the study has three aims: (1) to examine whether an existing trust model is a good fit for COVID-19–related information seeking online, (2) to examine differences in affective responses to digital resources about COVID-19 vaccination versus general information about COVID-19, and (3) to examine whether searching had a self-reported impact on vaccination decisions or attitude toward COVID-19 passports.

Methods

Design

A cross-sectional survey was conducted in January 2022. At this time in the United Kingdom, the Omicron variant wave had just peaked, mask use was still advised but no longer compulsory in indoor settings, and self-isolation after a positive test result was still a legal requirement. We collected quantitative data from eHealth users regarding their use of health websites in relation to COVID-19. We used Prolific to recruit a representative UK sample.

Participants

A total of 600 people completed the survey. In total, 525 participants indicated they had looked for COVID-19 information online. Of these 85.3% (448/525) had looked for more general information and advice about COVID-19 while 14.7% (77/525) had looked for information specifically on the vaccine. Full details of participant demographics can be found in Table 1.

Participants were asked whether they had gone online to look for health advice and information about COVID-19. Those answering "yes" were asked to indicate whether they had been searching for general health advice about COVID-19 or whether they had been searching for health advice about COVID-19 vaccinations. Participants then completed a series of questions relating to the last time they searched for health advice about COVID-19 online. Specifically, they were asked to "think about any one digital source that you visited during that search" and to answer the remaining questions with respect to that source. They answered questions relating to the impact of health advice on their coping perceptions and intention to act on the advice, the degree to which they trusted the information and the digital source, their attitude toward COVID passports, for example, the NHS app that shows proof of vaccination and demographic information.

Measures

Unless stated otherwise, participants answered the following measures on a 5-point Likert scale (1=strongly disagree to 5=strongly agree).

General Web Trust Questionnaire

The general web trust questionnaire contained 36 items from the study by Sillence et al [15] alongside measures of coping, information corroboration, and affective responses also taken from Sillence et al [15]. Specifically, coping was measured by asking participants to respond to the following stem and variables "After I read the information about COVID-19 I felt…" (1) in control and (2) optimistic using a 5-point scale with the labels: 1=less, 2=slightly less, 3=no different, 4=slightly more, and 5=more (Cronbach α=.84.). Additional affective responses, worried, reassured, at risk, confused and anxious were measured using the same format.

Information corroboration with other sources of information was measured with the following 4 items: (1) "I checked other websites," (2) "I checked other sources," (3) I found the advice consistent across other websites or apps, and (4) I found the advice consistent across other sources (Cronbach α=.87).

Impact on vaccination decision was measured using a single item developed for this study: "To what extent did the information and advice you read online impact your decision regarding COVID vaccinations?" Responses were given on a 5-point scale from "1=It did not influence at all" to "5=It influenced to a very large degree."

Attitude toward COVID-19 passports was measured using a single item developed for this study, that is, "I think COVID passports are a good idea" (1=strongly disagree to 5=strongly agree).

Outcome Measures

Trust was measured following Sillence et al [15], using the mean response to the following 2 items: (1) "I trusted the site" and (2) "I felt I could trust the information on the site" (Cronbach α=.95). Intention to act was an outcome measure, assessed with 1 item "I intended to act upon the advice." This item was taken from Sillence et al [15].

Ethical Considerations

The study received full ethical approval from Northumbria University ethics committee (REF:33639). The survey was hosted on Qualtrics and all data was anonymized. The first page provided participants with information detailing the aim, length, data storage, contact details, and withdrawal process of the study. They were then asked to provide informed consent. Participants received £1.25 (€1.49; US $1.66) for taking part in the study and the average completion time was around 7 minutes.

Results

Overview

We first explored the general web trust questionnaire by performing principal component analysis (PCA). We then explored the relationship between the factor structure and outcomes by testing its fit to the sampled data using structural equation modeling (SEM).

Properties of the General Web Trust Questionnaire

The 36 items of the scale were entered into the PCA. All items loaded onto the extracted components but any items with factor loadings lower than 0.30 were suppressed (Table 2). The analysis indicated that 5 components possessed eigenvalues greater than 1 and together explained 68.7% of the variance in keeping with accepted conventions for successful PCA [31]. The Familiarity factor is the weakest of those extracted although it does meet the minimum threshold of comprising three items [32].

Exploring the Relationship Between the Trust Questionnaire and Self-Reported Behavioral Outcomes

The data were further analyzed using SEM performed in analysis of moment structures using the maximum likelihood estimation method on the item covariance matrix. The specified model was based on Sillence et al [15] and modified to incorporate the new 5-factor structure. The goodness of fit indices supports the specified model. The chi-square value indicated poor fit (χ^2_{773}=1265.5; P<.001). However, this test is considered too sensitive for samples over 200 and here the sample size is 448. The Cmin/*df* value of 1.64 indicates a good fit. The goodness of fit and adjusted goodness of fit values of .89 and .86 respectively indicate adequate fit [33]. The comparative fit index value of .97 indicates good fit [34], as does the root mean square of approximation value of .04, 90% CI .034-.041 [35].

The model accounted for 64.7% of the variance in trust, 8.7% in coping, 9.7% in information corroboration, and 40.3% in intention to act. All beta path coefficients including those in Figure 1 and those that were not significant were inspected in evaluating the predictive power of the model and are presented for completeness in Table 3.

Figure 1. The trust model with significant standardized path coefficients.

XSL•FO
RenderX

Table 3. The unstandardized path weights and critical ratio (ie, *z* score) values for the main effects of the hypothesized full model.

Parameter	Unstandardized path coefficient	Critical ratio	*P* value
Credibility and impartiality			
Trust	.93	9.79	<.001
Information corroboration	.17	1.07	.29
Usability			
Trust	–.05	–.36	.72
Information corroboration	.39	1.56	.12
Familiarity			
Trust	–.04	–.64	.52
Information corroboration	.12	.98	.33
Privacy			
Trust	–.19	–2.43	.02
Information corroboration	.06	.41	.68
Personal experience			
Trust	–.001	–.03	.98
Information corroboration	.09	2.78	.01
Trust			
Coping	.27	4.89	<.001
Intention to act	.80	15.23	<.001
Coping–intention to act	–.04	–.67	.50
Information corroboration			
Trust	.001	.03	.98
Intention to act	–.02	–.61	.54

Only Credibility and Impartiality were found to possess a significant positive path to Trust. Privacy had a weaker yet significant negative path, meaning privacy assurances were associated with lower trust. Familiarity, usability, and personal experience (PEx) were not significantly predictive of Trust. Only Trust was found to significantly predict the intention to act on the advice. In addition, Trust significantly predicted Coping, suggesting that trustworthy websites heighten individuals' coping perceptions, making them feel more in control and optimistic. PEx significantly predicts Information Corroboration, suggesting that people are exploring a little further than the original digital source; however, this corroboration process does not appear to be affecting their level of trust or intention to act.

Comparison of Two Populations

Although the relatively small sample size for the vaccine information group meant that a comparable SEM model could not be reliably tested a series of independent samples *t* tests were used to compare the two groups on the key variables of interest (Tables 4 and 5).

Table 4. Mean (SD) values for key outcome variables.

Group	Trust	Intention to act	Corroboration	Impact on the decision regarding vaccination	Attitude toward COVID-19 passports
Searching for information on vaccinations (N=77)	4.22 (.91)	4.10 (1.05)	3.49 (1.24)	2.90 (1.21)	3.38 (1.51)
Searching for information on COVID-19 (N=448)	4.33 (.74)	4.13 (.89)	3.49 (1.06)	2.74 (1.39)	3.51 (1.36)

XSL•FO

Table 5. Mean (SD) values for "after I read the information" variables.

Group	Worried	Reassured	At risk	Confused	Anxious	Optimistic	In control
Searching for information on vaccinations (N=77)	2.27 (1.11)	3.84 (.95)	2.40 (.98)	2.14 (1.13)	2.42 (1.20)	3.66 (1.11)	3.57 (1.13)
Searching for information on COVID-19 (N=448)	2.48 (.88)	3.68 (.77)	2.84 (.88)	2.15 (.98)	2.76 (.97)	3.27 (.81)	3.42 (.85)

Independent Sample *t* tests

There was no significant difference between groups for trust (t_{523}=–1.169; *P*=.24; Cohen *d*=–.14, 95% CI –.386 to .098), intention to act (t_{523}=–.187; *P*=.85; Cohen *d*=–.02, 95% CI –.265 to .219), corroboration (t_{523}=–.038; *P*=.97; Cohen *d*=–.01, 95% CI –.247 to .237), impact on decision regarding vaccination (t_{523}=.934; *P*=.35; Cohen *d*=.115, 95% CI –.127 to .357), or COVID-19 passports (t_{523}=–.773; *P*=.44; Cohen *d*=–.095, 95% CI –.337 to .146).

Those searching for information on vaccinations (mean 2.40) felt significantly less at risk than those searching for general information on COVID-19 (mean 2.84; t_{523}=3.988; *P*<.001; Cohen *d*=–49, 95% CI –.735 to –.2348) and felt significantly less anxious (mean 2.42) than those searching for general information on COVID-19 (mean 2.76; t_{523}=–2.758; *P*=.003; Cohen *d*=–.34, 95% CI –.583 to –.097). Those searching for information on vaccinations (mean=3.66) felt significantly more optimistic than those searching for general information on COVID-19 (mean=3.27; t_{523}=3.760; *P*<.001; Cohen *d*=.464, 95% CI .220-.707).

There was no significant difference for the variable "In Control" (t_{523}=1.335; *P*=.18; Cohen *d*=–.165, 95% CI –.077 to .407) or for "Confused" (t_{523}=–.054; *P*=.96; Cohen *d*=–.007, 95% CI –.248 to .235). Finally, the variables "Worried" and "Reassured" approached but did not reach statistical significance (t_{523}=–1.813; *P*=.07; Cohen *d*=–.224, 95% CI –.466 to .019 and t_{523}=1.712; *P*=.09; Cohen *d*=.211, 95% CI –.031 to .453, respectively).

Digital Sources of Information

Table 6 shows the digital sources used. The majority of participants used either the NHS health care sources or the governmental sources for both general information and vaccine-specific information.

Digital sources were categorized as: (1) Governmental sources: official UK government website (Gov.uk), World Health Organization, Office of National Statistics, and Centre for Disease Control. (2) NHS health care sources: any page hosted on the NHS website (nhs.uk). (3) Other health care sources: any non-NHS health care website. This included The Mayo Clinic, WedMD, patient.co.uk, and the Health Check podcast. (4) News websites: any of the mainstream news providers, the majority of those reported were the BBC. (5) Search engines: where participants did not go to one source but reported explicitly using search engines, such as Google, to intentionally search for COVID-19–related information, rather than, for example, visiting a particular source (perhaps a source perceived as authoritative or trusted), such as the NHS, government, or BBC websites, and browsing the content from there. (6) Scientific journal: any peer-reviewed journal publishing academic research. (7) Specific health condition websites: any website dedicated to a specified health condition rather than a general health website, including asthma.org and Crohn's & Colitis UK. (8) Social media and forums: any online forum or social networking platform defined as user-driven and facilitating sharing of content, dialogue creation, and communication by and between users (in keeping with Kapoor et al, 2018 [36]). (9) Other: all instances where resources were not explicitly specified or where participants reported visiting multiple sources. All other resources are named individually in Table 6.

Table 6. Digital sources used.

Source	General information (N=448), n (%)	Vaccine specific information (N=77), n (%)
National Health Service health care sources	262 (58.48)	39 (50.65)
Governmental sources	64 (14.30)	11 (14.29)

Discussion

Principal Results

Trust continues to significantly influence self-reported intention to act on health information. In terms of trust predictors, only credibility and impartiality have a significant, direct, and positive relationship with trust. Privacy has a significant negative relationship with trust. Other predictors (familiarity, usability, and PEx) may be indirect and mediated through other trust variables. The variable PEx had a significant direct effect on information corroboration and trust was found to significantly relate to coping perceptions. The findings suggest a number of important discussion points.

First, the Sillence et al [15] trust model provides a reasonable fit for COVID-19–related health information online. Trust continues to predict intention and the credibility and impartiality of the digital source remains the strongest predictor of trust in digital health sources. However, compared to the 2019 model, the picture here is of a simpler trust process in which the credibility and impartiality factor does the "heavy lifting" in relation to trust compared to the other variables. Another key difference is the lack of a relationship between corroboration and trust. In earlier models, health information seekers looked to verify the information they found online by cross-checking with other digital and nondigital sources. Here we see only a direct relationship between the credibility and impartiality of the website and trust. One reason for this, given the predominance of the NHS as the most popular site for information and advice, is that our health information seekers are simply taking the website at face value providing it appears sufficiently credible and impartial. However, it is interesting that in an American sample, information seekers relied heavily upon often unreliable social media sources for information and advice, yet still engaged in relatively low levels of fact-checking [37] and so we must consider the possibility that people are being bombarded with so much information in relation to the pandemic that they simply switch off.

The role of PEx within digital sources is interesting here. While PEx significantly predicts information corroboration there was no subsequent relationship with trust. In the 2019 model [15] it was suggested that patient experiences can positively influence trust but only if users first corroborate the information through other sources. In our study, we suggest that people are checking up on these patient stories and experiences simply out of interest rather than as a way of assessing the trustworthiness of the information. When faced with a high degree of uncertainty and with limited detailed information, assessments of risk may be emotion-based [38], and people may well seek out other people's personal accounts of their COVID-19 experiences. Personal accounts are often engaging and are seen as more relatable than statistical information when it comes to decision-making [39]. While PEx is now embedded within a diverse range of digital resources, those more closely associated with personal content, for example, social media platforms or individual blogs, were generally underrepresented in the data we collected. Instead, we observed a reliance on official digital sources, in particular, the NHS website and government sources. In terms of pandemic or emergency, reliance on official sources may be more commonplace. Sillence et al [15] found that the majority of UK respondents cited the NHS website as their source of health information, and McNeill, Harris, and Briggs [40] noted that the main UK source to be retweeted during the H1N1 pandemic was NHS Choices. In this study, there was little reported use of social media, which is perhaps surprising and contrasts with other recent health pandemics in which social media use and misinformation have been prevalent [37,41,42] as well as in earlier studies examining the COVID-19 pandemic and the facilitation of conspiracy theories [43,44].

Despite generally high levels of mistrust in the government's overall handling of the pandemic [5], UK citizens still sought information from government sites. Moreover, we see a reliance on health professionals and public health information. In a time of limited information, there may be fewer options available to information seekers and individuals may be satisfied with seeking official sources of information even if they contain basic knowledge as opposed to more detailed, specific information. This contrasts with earlier work on trust in digital health information in which personalization or tailoring is seen as important to trust. People with long-term experience of a particular health condition often become experts by experience and may seek more specific, tailored digital resources to support their health conditions. This involves making more fine-grained assessments of the personal relevance of the information before deciding to trust or act upon the advice it contains [10,45] and is especially true where the condition is rare or less well known [46]. In the case of COVID-19, a worldwide pandemic affecting all age groups, it might be that generic information applicable to all sufficed in this case. There was little sense that people were checking COVID-19 information in relation to their other, pre-existing health conditions and specific health websites may not have had that information readily available. In light of research that shows how health information overload may lead to increased anxiety [47], our participants' reliance on relatively few, authoritative websites seems like a reasonable strategy. Too much, possibly conflicting, information about COVID-19 can leave an individual feeling overwhelmed and will ultimately lead to "information avoidance," which is clearly a poor outcome in the face of a global pandemic.

Unlike Sillence et al's [15] 2019 model, we note that privacy has a weak negative relationship with trust. The topic of privacy was raised repeatedly in relation to the discussion of contact tracing apps and COVID-19 passports and so while not directly related to the digital source being used it may be that being asked to think about the privacy features of sources stimulates a wider consideration of privacy and mistrust. Rather than privacy policies etc. being seen as an example of good practice, the very fact that these options were present on digital sources may have served as a reminder that data are being collected, processed, and often shared. Privacy nudges may well remind people of the need to be mindful of privacy but can also raise awareness of the data that is available for collection [48,49].

Second, trust significantly predicted coping suggesting that trustworthy websites heighten individuals' coping perceptions, making them feel able to cope. Interestingly, Wang et al [1] did not find an association between the use of the internet as an

XSL•FO
RenderX

information source on COVID-19 and self-confidence in coping with COVID-19 but did not focus on trusted websites.

Looking at the affective variables in more detail for the two groups (general information seeking and vaccination information), we see that those searching for vaccination information felt more positive—specifically, they felt less at risk, less anxious, and more optimistic after reading the information. Wang et al [1] found that vaccination information sources have different effects on students' coping appraisal of COVID-19 with information from medical personnel leading to greater knowledge about the mechanism of vaccination and greater response efficacy of vaccination compared to information from coworkers or colleagues. In terms of coping, during the H1N1 pandemic, those people who adopted a more problem-focused coping strategy including seeking out information to help solve problems were more likely to indicate they would be vaccinated [22]. In our data, those individuals who have gone looking for information about vaccination feel better for having done so.

Zheng et al [50] noted that vaccine information seeking is related to vaccination intention and suggested that health information seeking can be viewed as a coping behavior when people do not have sufficient knowledge of a particular health topic. Although seeking vaccine-related information online was also positively related to perceived vaccine information overload [50], it may be that sticking with a single trusted source is preferable for improved coping. Finally, there were no differences in terms of trust, intention to act on information, or attitude toward COVID-19 passports between participants who were searching for general COVID-19 health information versus those who had searched for vaccination information. This is unsurprising given the similarity of digital sources used.

In summary, people searching for general COVID-19 information as well as those searching for COVID-19 vaccine-specific information sought out official sources of information online. In terms of uncertainty when faced with a global emergent health concern people place their trust in familiar websites and rely on the perceived credibility and impartiality of those digital sources.

Limitations

It is important to note that data was purposely not collected during a period of national lockdown in the United Kingdom. The vaccination program was already well underway and COVID-19 passports were very much still on the agenda. People may have sought information from alternative digital sources had data collection taken place during a period of lockdown. Focusing on the United Kingdom made sense given the local regulations and practices in place, but it would be interesting to make comparisons with other countries going forward. The reliance on the NHS website in the United Kingdom would be interesting to compare with countries where different funding models exist for example where health insurance schemes mean there is no single free at the point of service system. Vaccine hesitancy is relatively low in the U and has declined since the start of the vaccination rollout program from 10% to 3% in September 2021 [51]. Other countries, for example, France, have much higher levels of vaccine hesitancy [52], and comparisons here in relation to trust around digital health resources would warrant further investigation. Finally, it is interesting to note that although we have used a one-shot cross-sectional methodology, we mirror findings from Zhang et al [53], who examined trust over several waves earlier in the pandemic and noted a decrease in the use of social media over time and an increase in trust in government information.

Conclusion

In conclusion, in the context of COVID-19, "credibility and impartiality" remain a key predictor of trust in eHealth resources but in comparison with previous models of trust in online health information, checking and corroborating information did not form a significant part of trust evaluations. In times of uncertainty when faced with a global emergent health concern, people placed their trust in familiar websites and relied on the perceived credibility and impartiality of those digital sources.

Abstract

Background: Many people seek health-related information online. The significance of reliable information became particularly evident due to the potential dangers of misinformation. Therefore, discerning true and reliable information from false information has become increasingly challenging.

Objective: This study aimed to present a pilot study in which we introduced a novel approach to automate the fact-checking process, leveraging PubMed resources as a source of truth using natural language processing transformer models to enhance the process.

Methods: A total of 538 health-related web pages, covering 7 different disease subjects, were manually selected by Factually Health Company. The process included the following steps: (1) using transformer models of bidirectional encoder representations from transformers (BERT), BioBERT, and SciBERT, and traditional models of random forests and support vector machines, to classify the contents of web pages into 3 thematic categories (semiology, epidemiology, and management), (2) for each category in the web pages, a PubMed query was automatically produced using a combination of the "WellcomeBertMesh" and "KeyBERT" models, (3) top 20 related literatures were automatically extracted from PubMed, and finally, (4) the similarity checking techniques of cosine similarity and Jaccard distance were applied to compare the content of extracted literature and web pages.

Results: The BERT model for the categorization of web page contents had good performance, with F_1-scores and recall of 93% and 94% for semiology and epidemiology, respectively, and 96% for both the recall and F_1-score for management. For each of the 3 categories in a web page, 1 PubMed query was generated and with each query, the 20 most related, open access articles within the category of systematic reviews and meta-analyses were extracted. Less than 10% of the extracted literature was irrelevant; those were deleted. For each web page, an average of 23% of the sentences were found to be very similar to the literature. Moreover, during the evaluation, it was found that cosine similarity outperformed the Jaccard distance measure when comparing the similarity between sentences from web pages and academic papers vectorized by BERT. However, there was a significant issue with false positives in the retrieved sentences when compared with accurate similarities, as some sentences had a similarity score exceeding 80%, but they could not be considered similar sentences.

Conclusions: In this pilot study, we have proposed an approach to automate the fact-checking of health-related online information. Incorporating content from PubMed or other scientific article databases as trustworthy resources can automate the discovery of similarly credible information in the health domain.

Introduction

With rapid progressions in the digital age, and the vast dissemination of textual information available online, the likelihood of coming across misinformation has surged [1,2]. Misinformation refers to information that is untrue, incorrect, or deceptive in nature [3]. It is prevalent across various domains, with social media being a particularly prominent source [4]. Indeed, many people seek health-related topics on modern platforms and websites available online [5]. Inaccurate health-related information, however, poses an even greater risk, as it can directly impact lives [6,7]. Health misinformation is considered "a health-related claim or information which is not correct due to a lack of scientific evidence or knowledge" [4,8]. The importance of trustworthy online health information became particularly clear during the COVID-19 pandemic, which triggered a new crisis known as the COVID-19 infodemic. An infodemic refers to the excessive spread of false or misleading information across both digital and physical spaces [9] causing confusion and detrimental outcomes, as it underscores the potential risks posed by inaccurate or deceptive information to individuals [3,10]. The infodemic often manifests across 4 key areas: scientific research, policy and health care practice, news outlets, and social media platforms [11]. As a result, distinguishing between true and reliable information and falsehoods has become increasingly challenging. The labor-intensive process of manually verifying information specifically in health-related fields demands expert oversight and consumes significant time [4,9,12]. Therefore, it is crucial to establish an automated fact-checking process to help users identify the accuracy of health-related information available online.

The fact-checking process involves evaluating the truthfulness of information and consists of 3 key tasks: claim detection, evidence retrieval, and claim verification [12]. The first 2 tasks can be considered as factual verification, while the third focuses on assessing the accuracy of claims, which involves distinguishing reliable information from falsehoods to establish their factual validity [13].

Several studies have explored automating the fact-checking process, primarily focusing on misinformation in the form of fake news on websites [4,14,15] or social media [2,7,16-18]. These studies have generated synthetic datasets as the gold standard to facilitate the automation of evidence-based fact-checking. Thus, they compiled datasets comprising information or claims along with their corresponding evidence from trusted sources. Models were then trained using these datasets to automate the fact-checking process [7,10,15,17-20]. To create a database of verified claims, they used methods such as modifying phrases from Wikipedia [20], manual selection of quotation sentences and handpicking of claims from health news sites [14,15,21], and automatic selection of verified claims that were manually done by experts of journalists from fact-checking websites [10]. For example, the FEVER dataset, generated by modifying sentences taken from Wikipedia, consisted of 185,400 claims [22]. PUBHEALTH is another dataset containing false, true, unproven, and a mixture of health-related claims. The dataset also had a column containing journalist-crafted, gold-standard explanations designed to substantiate the fact-check labels assigned to each claim [6,18]. While synthetic datasets provide valuable contributions to advancing automatic fact-checking efforts, they cannot fully address real-world challenges, particularly the need for real-time, dynamic information [23]. Therefore, there is a need that claims and their associated evidence to be automatically extracted [24]. A study [25] developed a Large Language Model called TrumorGPT, which addresses limitations in fact-checking by incorporating retrieval-augmented generation and using continually updated knowledge graphs. This approach uses few-shot learning, knowledge graph construction, and semantic reasoning, which enhances the model's ability to handle fact-checking tasks effectively. Another recent survey [12] explored automated techniques for predicting the veracity of claims, relying on natural language processing, knowledge representation, and databases. This study identified common challenges in fact-checking research and emphasized the importance of information retrieval and knowledge representation, particularly due to the rapid emergence of new claims.

Therefore, a key element of fact-checking involves identifying credible sources, and for health information, leveraging up-to-date scientific literature is essential as it is widely regarded as 1 of the most trustworthy references [26]. Indeed, numerous platforms and databases provide access to health-related and scientific literature, including Google Scholar, PubMed, ScienceDirect, and Web of Science, among others. These databases can be used as a reliable source for the automation of all the processes.

Numerous organizations have established guidelines to aid users in identifying trustworthy claims [27,28] where time-consuming manual recognition plays an important role in the process. In this pilot study, we proposed a novel automated evidence-based fact-checking approach that aims to identify and confirm accurate, truthful information using scientific literature and research databases as sources of truth. This exploratory evaluation highlights how using this approach may help users measure the extent of confidence in a web page and make informed decisions about accepting the health-related information of a website. Thus, the objective was to assess the truthfulness of health-related information through an evidence-based approach, without creating a synthetic database of claims-evidence but leveraging PubMed as a reliable source of fine-grained and up-to-date health-related information.

Methods

Approximately 1000 web pages were provided by Factually Health company on January 31, 2023. This company specializes in identifying reliable health-content websites [29]. The web pages were selected through random sampling within various disease categories to ensure a balanced dataset while minimizing the risk of overrepresentation of any single category. This approach accounted for variations in the number of available websites across disease categories. The web pages then underwent manual cleaning. Redundant pages were removed, and those unsuitable for research were excluded based on the

XSL•FO
RenderX

following criteria: pages primarily featuring video content, pages related to clinical studies, pages resembling anecdotes rather than factual health information, or pages that restricted data extraction by Python (Python Software Foundation) libraries.

After this process, a dataset comprising 538 web pages was finalized. These web pages represented a diverse range of diseases, including arthritis (81 pages), chronic obstructive pulmonary disease (79 pages), COVID-19 (66 pages), hypertension (66 pages), lung cancer (70 pages), prostate cancer (66 pages), and diabetes (110 pages).

The selection of diverse disease categories was intended to minimize potential bias in the analysis. However, our previous study demonstrated that the selected diseases did not significantly impact classification results [29]. Using the URLs of each web page, the content was extracted as text files using the "justext" library in Python, to remove additional links and extraneous content from websites, such as navigation links, headers, and footers.

The process included the following three steps: (1) Classification of web page content into 3 thematic categories, semiology, epidemiology, and management by evaluating various transformer models, including bidirectional encoder representations from transformers (BERT), SciBERT, and BioBERT, as well as traditional models such as random forest (RF) and support vector machine (SVM), (2) automating the creation of PubMed queries combining "WellcomeBertMesh" and "KeyBERT" models, (3) automatic extraction of top 20 related literatures from PubMed, and (4) applying similarity checking techniques of cosine similarity and Jaccard distance to compare the content of extracted literature and web pages vectorized using BERT tokenizer. As a reliable source of truth, PubMed was a suitable choice to find evidence for health-related claims. PubMed, an open-source platform dedicated to facilitating searches and retrieval of health-related literature, encompasses over 36 million papers [30].

Classification of Web Page Contents

One of the necessary stages before determining the veracity of a claim or information is to detect the sentences that need to be verified [31]. These claims are crucial to the content's main point but require verification through an annotation schema and developing a benchmark for automated claim detection [14,31]. To detect sentences that need to be verified, two major steps were taken: (1) the identification of 3 thematic categories of content and (2) the classification of web page content according to these categories.

The Content Categories

To compare web page content with materials from the scientific literature database, it was essential to categorize the content, ensuring that comparisons were made within the relevant subject. Three distinct thematic categories have been identified for analysis: epidemiology, semiology, and management. In the epidemiology category, we included all sentences related to the statistics of a disease, the population, the frequencies, the causes, the risk assessment of the disease, and all public health-related information about the disease (eg, as of 2014, the global prevalence rate of rheumatoid arthritis was about 0.24%). In the semiology category, we considered all sentences related to signs (eg, high blood pressure is another sign of the disease) and symptoms (eg, this disease has symptoms such as pain, discomfort, weakness, fatigue). Finally, for the management category, we considered all the sentences linked to therapeutic approach (eg, drug treatment and surgical intervention, prevention, and the element of paraclinical diagnosis of diseases (eg, a complete medical examination carried out by a doctor can better determine if a person has chronic obstructive pulmonary disease and the degree of severity of the disease).

Manual Annotation and Model Development

Two authors (AB and AA) independently annotated 200 web pages on a sentence-by-sentence basis considering the 3 categories of epidemiology, semiology, management, and neutral until reaching a roughly balanced amount of data across all classes [32]. We used the Cohen κ score to assess the agreement between the 2 reviewers AB and AA). Any discrepancies were resolved by the third author (JNN).

Neutral sentences were those that did not correspond to any of the defined thematic categories. Table 1 shows the distribution of sentences for each category. The portable serverless text annotation tool of MedTator-1.3-11 [33] was used for the annotation process. A total of 3 transformer models of BERT, SciBERT, and BioBERT were used to classify the sentences into the 4 mentioned categories. The BERT model has demonstrated superior performance in several text classification tasks [29,34,35]. SciBERT is an extension of BERT and is trained on a vast corpus of scientific literature spanning multiple domains [36] and BioBERT is pretrained using an extensive corpus comprising PubMed abstracts (PubMed) and full-text articles from PubMed Central [37]. We have also conducted a performance comparison between the transformer models and 2 traditional machine learning models: RF and SVM.

Table 1. The distribution of classes.

Category	Number of sentences
Neutral	3162
Semiology	851
Epidemiology	1171
Management	1066

XSL•FO

The "BertTokenizer" library has been used to tokenize the incoming sentences, with the following parameters: We applied a maximum sequence length of 128 to standardize the size of each input sentence. To optimize the model's hyperparameters, we applied the Bayesian optimization approach using the 'BayesianOptimization' library in Python. The hyperparameter tuning spaces are detailed in Table 2.

Table 2. Hyper-parameter tuning search space.

Hyper-parameters	Range	Best trial
Learning rate	10^{-7}, 10^{-2}	3×10^{-5}
Weight decay	10^{-5}, 10^{-1}	10^{-3}
Number of epochs	(1:5)	3
Batch size	(8,16,32,64)	32

Automating PubMed Query Generation

Overview

Literature extraction involved identifying scientific articles within PubMed to support the process. To achieve this, the approach requires the formulation of a query by combining keywords and Medical Subject Headings (MeSH) terms, which can be extracted from web page content. This process included three steps: (1) Automating PubMed subquery creation from MeSH terms and creating a subquery using the "WellcomeBertMesh" model, (2) Automating PubMed subquery creation from keywords using KeyBert model and creating a subquery, and (3) Construction of the final query by combining the different subqueries.

Automating PubMed Subquery Creation Using MeSH Terms Extracted by Transformers

All the MeSH terms were extracted from the text using a pretrained model of "WellcomeBertMesh," which takes its inspiration from "BertMesh," which undergoes the pretraining using the entire text of biomedical publications and is built upon the foundation of the BioBert pretrained model [38]. Given that our evidence for the websites primarily comprised health-related articles from PubMed, we selected this model. Its architecture is rooted in the latest advancements in the biomedical field, prominently featuring Microsoft's cutting-edge "PubMedBert" as its core framework [38].

To enhance the accuracy of the subquery, the identified MeSH terms were initially organized according to their MeSH categories to construct subsubqueries. The MeSH has a tree structure that is organized hierarchically, visually presenting descriptors in broader and narrower relationships. The top tier of the MeSH tree structure encompasses 19 comprehensive categories. While these terms are not included in MeSH data maintenance and distribution, they can be used to search PubMed by using the search term "category" [39]. Therefore, we have considered the MeSH terms under each head category together using the "OR" operator in this subsubquery. Then, we constructed the subquery using the "AND" operator between extracted MeSH terms in different categories. The pseudo-code for this step is presented in Figure 1.

for $i \leftarrow 1, n$ **do**:

    for $k \leftarrow 1, K$ **do:**

        $sub\text{-}subquery_1, sub\text{-}subquery_2 \leftarrow null$

        /* put OR for mesh terms in the same category, put AND for different categories*/

            if $mesh_i$ belong to same $category_k$ **then**

                $sub\text{-}subquery_1 \leftarrow (mesh_i$ OR $sub\text{-}subquery_1)$

            Else

                $sub\text{-}subquery_2 \leftarrow (mesh_i$ AND $sub\text{-}subquery_2)$

            end if

        $MeSH\text{-}sub_query \leftarrow (sub\text{-}subquery_1$ AND $sub\text{-}subquery_2)$

    end for

end for

Automating PubMed Subquery Creation Using Key Phrases Extracted by Transformers

The key phrases from web page contents have been extracted using the transformer model "KeyBERT" library, which is described in previous literature as having the best performance in extracting the key phrases [40], especially for long texts [41], which aligns with our need of extracting the key phrases of the scientific papers. The extracted keywords were combined with the "AND" operator to create a subquery.

Figure 2 shows the proposed pseudo-code to extract the keywords for the creation of the subquery.

model ←***Load*** the "KeyBERT" pre-trained model

/* computing a vector representation and extracting the key phrases corresponding to each sentence */

for $i \leftarrow 1, n$ **do**

    $v_i \leftarrow$ model_vector (s_i)

    $keyphrase_i \leftarrow$ model (v_i)

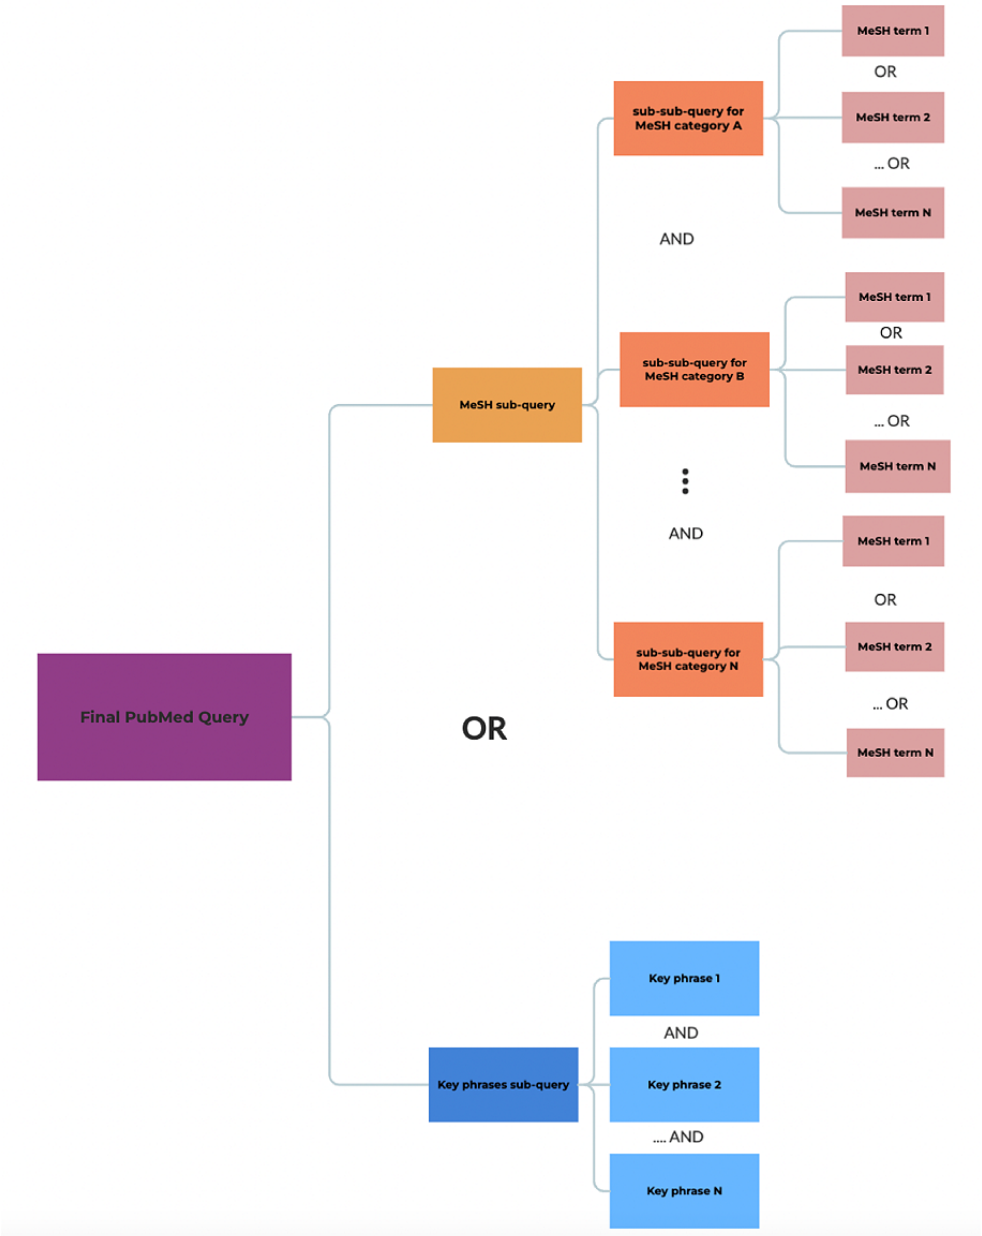
end for

/* creating key phrase subquery tailored to the specified categories */

keyphrase_query ← *null*

for $i \leftarrow 1$, *length(keyphrases)* **do**

    keyphrase_query ← (*keyphrase_query* AND $keyphrase_i$)



end for

Construction of the Final Query

The subqueries extracted from the preceding processes were combined using the "OR" operator to construct the final query. Figure 3 presents a comprehensive overview of the process used to construct the final PubMed query, summarizing the structure and strategy behind its creation.

XSL•FO
RenderX

Figure 3. Detailed process diagram for the development of the comprehensive final PubMed query.

Automating Related Literature Extraction

The final query was used to retrieve a compilation of articles, from which the top open access 20 resulting papers were extracted. The “PMC_ids” of papers were extracted using the “Entrez” library of Python that provides integrated access to PubMed Medline [42]. To evaluate the quality of our query results, we conducted a comprehensive review of the obtained full-text papers. In our assessment of the extracted papers in PubMed, those subjected to filtering within the systematic reviews and meta-analysis category exhibited more related papers to the subject of the research, compared with papers that were not subject to such filtering. Consequently, we selected them to encompass a wider range of relevant articles.

Finally, the automatically extracted papers were manually checked to be pertinent considering the title of the papers, the irrelevant papers were removed and excluded from the final process.

Similarity Detection and Fact-Checking

For the process of computing the similarity measure between different sentences, for each disease, we randomly selected 5 web pages in our dataset. For each of the 3 predefined thematic categories in a web page, 1 PubMed query was generated and with each query, the 20 most related, open access articles within the type of systematic reviews and meta-analysis were extracted. The following steps were then carried out: (1) Categorizing the extracted related literature content based on the 3 thematic categories. This was necessary to analyze sentences (from websites and scientific articles) that are relevant to the same topics. (2) Comparing by thematic category, the content from scientific articles and web pages to identify similar sentences.

XSL•FO
RenderX

Finally, after conducting a manual evaluation of the identified similar sentences, we calculated the average number of categorized sentences for each randomly selected web page, as well as the average number of credible sentences detected. Credible sentences refer to those in the related literature that demonstrated similarity with the sentences from the web pages.

Categorizing the Extracted Literature

The more performant fine-tuned model on the web page contents was used to categorize literature contents into 3 thematic categories. This approach enabled us to facilitate a direct comparison between sentences sharing the same thematic context.

Comparing the Content From Literature and Web Pages to Identify Similar Sentences

For the sentence comparison, we used the BERT vectorizer to transform the texts into vectors. This allowed us to encode the semantic significance of sentences as numerical values, facilitating the application of different similarity detection algorithms [43].

Both scientific articles and web page sentences were transformed into vector representations, taking into account their respective thematic categories. Subsequently, each web page sentence was compared with scientific article sentences of the same category using the cosine similarity and Jaccard technique. A similarity threshold of 87% was chosen to determine sentence selection, ensuring that sentences with over 87% similarity were chosen.

Figure 4 shows the proposed pseudo-code for the similarity-checking part.

Figure 4. Paper similarity detection.

Input: A list of sentences belonging to a web page and papers $S = [s_1, s_2, \ldots]$, $P = [p1, p2, \ldots]$

Input: *category* to check ∈ {*Epidemiology, Semiology, Management*}, *similarity_threshold*

Output: percentage of similarity between two contents

model ←***Load*** the "bert_base_uncase" pre-trained model

/* computing vector representation of paper sentences */

for $i \leftarrow 1, n$ **do:**

    $v_i , v'_i \leftarrow$ model_vector (s_i, p_i)

end for

/* computing the percentage of similarity between the contents of the web page and the papers*/

for $k \leftarrow 1$, *length* (v_i) **do**

/* if the similarity between web page and the paper sentences be more than threshold*/

    if *Cosine_similarity* $(v_i, v'_j \in_{(1\ldots n)}) >$ *similarity_threshold* **then**

      print (corresponding sentences of (v_i, v'_j)*)*

    end if

end for

compute similarity percentage

For each disease, we randomly selected 5 web pages and extracted both their related papers and similar sentences. It was due to the inherent variability and specificity of medical information related to each disease. Diseases often exhibit unique characteristics, nuances, and clinical considerations. By prioritizing diseases, we aimed to provide a more granular and clinically relevant assessment of the similarity between the sentences. The outcomes, comprising sentences from the web pages and their corresponding similar sentences, underwent a manual verification by the authors to ensure semantic similarity between them. Subsequently, the proportion of semantically similar sentences between a web page and its related reference papers was calculated.

Ethical Considerations

This research relied solely on publicly accessible data and did not involve any human or animal participants, making it exempt from the need for ethical approval. The study strictly adheres to established data privacy norms to prevent any compromise of confidentiality or privacy. In addition, the project does not include any direct involvement or interactions with individuals, thereby minimizing potential ethical issues. The University of

XSL•FO
RenderX

Montreal's Research Committee has carefully examined our methodology and affirmed that this study falls outside the scope of Medical Research Involving.

Results

This section elaborates on the results of each part of the proposed pseudo-codes.

Classification of Web Page Contents

The annotation process for web page contents achieved a Cohen κ score of 87% among the 2 annotators (AA and AB), indicating high agreement between the annotators and ensuring the reliability of the data used for model evaluation.

The performance of transformer-based models (BERT, BioBERT, and SciBERT) was compared to traditional machine learning models (RF and SVM) for categorizing web page content into four categories. BERT emerged as the most effective model, consistently achieving superior precision, recall, and F_1-scores across all categories. Traditional models, in contrast, demonstrated lower performance, particularly in terms of F_1-scores, indicating limitations in balancing precision and recall effectively.

Table 3 illustrates the performance of the classification models used to classify the content of web pages. The performance matrix includes metrics such as precision, recall, and F_1-score.

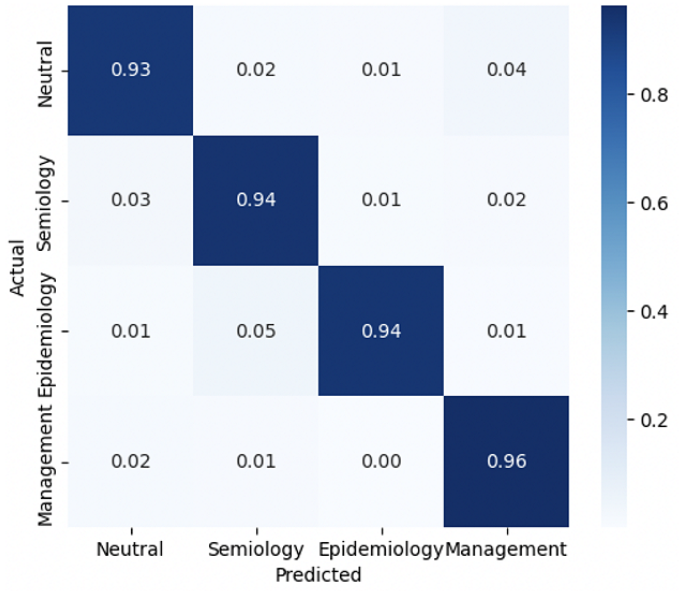
Table 3. Performance evaluation of the BERT (Bidirectional Encoder Representations from Transformers) and machine learning models for web page content classification across considered categories.

	BERT[a]			BioBERT			SciBERT			RF[b]			SVM[c]		
Classes	Precision	Recall	F_1-score	Precision	Recall	F_1-score	Precision	Recall	F_1-score	Precision	Recall	F_1-score	Precision	Recall	F_1-score
Neutral	0.96	0.93	0.95	0.88	0.83	0.85	0.85	0.81	0.83	0.51	0.92	0.66	0.72	0.81	0.77
Semiology	0.91	0.94	0.93	0.81	0.81	0.81	0.77	0.79	0.78	0.96	0.05	0.09	0.71	0.59	0.64
Epidemiology	0.92	0.94	0.93	0.80	0.76	0.76	0.75	0.74	0.75	0.8	0.1	0.1	0.69	0.62	0.65
Management	0.95	0.96	0.96	0.83	0.89	0.89	0.83	0.87	0.85	0.59	0.58	0.59	0.74	0.73	0.74

[a]BERT: Bidirectional Encoder Representations from Transformers.

[b]RF: random forests.

[c]SVM: support vector machines.



According to Table 3, among the transformer models, the BERT model had a promising performance with more than 93% recall for neutral sentences, 94% for semiology and epidemiology, and 96% for the management category. The model had an F_1-score of 95% for neutral sentences, 93% for semiology and epidemiology, and 96% for management. The model had 96% precision for neutral sentences, 91% for semiology, 92% for epidemiology, and 95% for management. Also, traditional models did not have high performance, the precision values for both RF and SVM were relatively low in some classes, indicating a high rate of false positives. Also, the F_1-scores for both RF and SVM were generally lower compared with the BERT model, indicating that they may not achieve a good balance between precision and recall. Therefore, the BERT model was selected for the classification of the web page contents.

The confusion matrix for the BERT model is shown in Figure 5, providing a detailed visualization of its classification performance across the different categories.

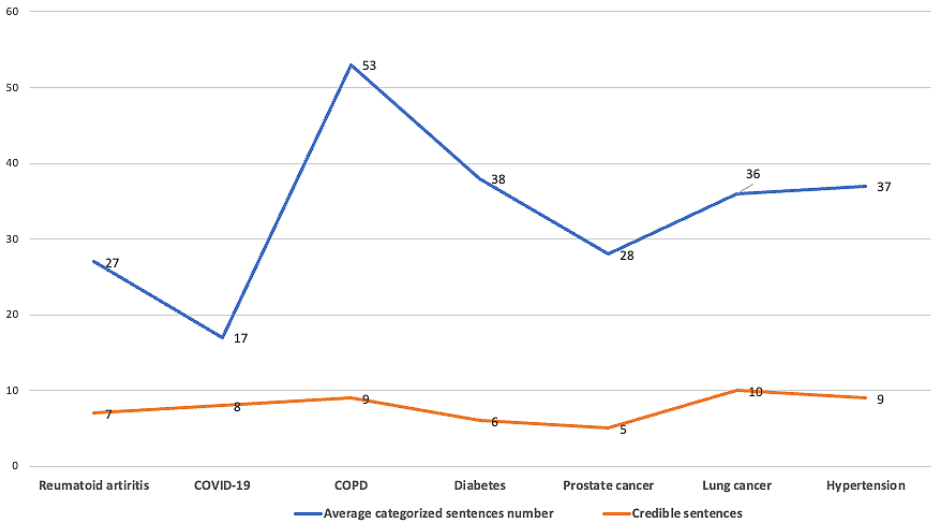
Figure 5 shows the confusion matrix for the BERT classifier, which correctly classified 0.93 of the neutral sentences, 0.94 for both the semiology and epidemiology sentences, and 0.96 for management sentences as true positives.

XSL•FO
RenderX

Figure 5. Bidirectional encoder representations from transformers model performance: confusion matrix for the classification of web page sentences into 3 thematic categories.

Automating PubMed Query Generation

To extract relevant literature for the web pages categorized thematically, a PubMed query was generated for each of the 7 diseases. Each query retrieved the 20 most related papers. The titles of the retrieved papers were manually evaluated, and less than 10% were deemed irrelevant, demonstrating the effectiveness of the generated queries. These irrelevant articles were excluded from further analysis.



This result highlights the utility of using MeSH terms and key phrases in constructing PubMed queries, which efficiently yielded pertinent literature. The generated weblinks for accessing the papers followed the format: "https://pubmed.ncbi.nlm.nih.gov/PMID/," with PMIDs obtained directly from the PubMed queries.

Similarity Detection and Fact-Checking

Figure 6 illustrates the average percentage of credible information found in the 5 randomly selected web pages categorized by related diseases. Credible information is defined as sentences in the web pages that were successfully matched with corresponding sentences in PubMed articles.

On average, 23% of the sentences on each web page were identified as similar to statements in the scientific literature. While this demonstrates the potential of the system to detect credible content, a significant challenge arose with false positives. Some sentences achieved a similarity score exceeding 80% but were semantically dissimilar upon closer inspection.

Figure 6. The average number of credible sentences on web pages (red line) versus the average number of all sentences on each web page (blue line). COPD: chronic obstructive pulmonary disease.

XSL•FO
RenderX

For instance, the following sentences from an extracted paper and a web page had a similarity score of 88% yet conveyed different meanings:

1. “Previous studies have documented residual symptoms that continue 12 weeks after the onset of acute COVID-19, known as post-acute or long COVID-19.”

2. “The acute phase of COVID itself can last for up to 14 days.”

This highlights the need for more sophisticated approaches to accurately distinguish between syntactic similarity and genuine semantic alignment.

As an illustrative example, for the rheumatoid arthritis category, we randomly selected 5 web pages, each containing an average of 27 sentences distributed across 3 thematic categories: epidemiology, semiology, and management (represented by the blue line). Among these, an average of 7 sentences per web page were deemed credible and successfully matched to corresponding statements in the scientific literature (depicted by the red line).

Discussion

Principal Findings

In the present pilot study, our objective was to automate aspects of the fact-checking process for online health information. While previous research [21,26] has explored automation in various stages of fact-checking, such as evidence retrieval or claim identification, this pilot serves as an initial step toward achieving full automation in the fact-checking process. Our approach includes the automation of identifying verifiable sentences through a classification process. Notably, our study used a fine-tuned BERT model, which exhibited notable efficacy in categorizing health-related sentences. Although BioBERT and SciBERT models have been reported to outperform BERT in various downstream tasks [36,37], in our investigation, the BERT model demonstrated superior performance. This discrepancy could be attributed to BERT training on general-purpose texts, such as Wikipedia or Book Corpus [35], which align more closely with the content of websites targeted at general populations. In contrast, BioBERT and SciBERT are trained on more specialized texts, such as scientific publications [36,37].

Previous research [14,31,44] has shown that the identification of claim-worthy sentences or the recognition of key information needing verification from reliable sources is a fundamental first step in automating the fact-checking process akin to our approach. This process is commonly structured as a text classification task. The previous studies used human annotators [44] or crowdsourcing [31] to tag claim-worthy sentences and trained machine learning models to classify them. A previous study [14] focused on detecting claims within news and public information, assigning each sentence a likelihood score for containing significant factual claims. Also, automating the fact-checking process is far from straightforward, as it necessitates the utilization of artificial intelligence tools to struggle with the complexity of text and context [10]. Studies often considered the problem as a binary classification to split the contents into credible or non-credible information, however, the decision is more complex since there may be several ambiguities in the sentences. In addition, several parts of the process depend on human judgment, which needs further research in the area. Building on this groundwork, our study applied a BERT-based classification approach to detect health information requiring verification and automatically proposing a sentence for this process. Previous studies relied on reviewer selections to develop claim and evidence datasets, lacking attempts to automate claim identification with real-world resources [17,18,45].

In addition, rather than constructing a manual reference dataset as the evidence for verifiable sentences, we leveraged the PubMed database as our source of truth. We automated the detection of evidence for claims made on web pages in an unsupervised approach, streamlining the verification process. This aligns with previous studies [21,26] that used PubMed publications as evidence, using transformer models to generate queries and retrieve documents from PubMed. We demonstrated the effectiveness of using transformer models to extract MeSH terms and key phrases from web page content, enabling the efficient generation of PubMed queries. This approach facilitated the retrieval of related articles from scientific references without requiring supervision. According to a previous study [14], to verify the veracity of the claims, it is crucial to translate them into queries against the reference databases. However, other studies [6,20,22] created a knowledge database as the references to compare with the claims. Notably, Sarrouti et al [6] introduced a dataset comprising evidence-claim pairs, manually annotated as SUPPORT, REFUTE, and NEUTRAL. They used BERT-based models to create a realistic testing ground for evidence-based fact-checking systems.

To assess the alignment between claim sentences and extracted references, we measured their similarity, a practice supported by [46]. This study underscores the necessity for a model in claim verification to measure the semantic similarity between claims and verified factual knowledge or references. To compare the semantic similarity, we used a transformer-based representation that converted the textual content into vectorial representation, allowing us to capture the contextual nuances of each sentence consistent with previous approaches [19,43,47]. This approach is more efficient and produces semantically richer sentence representations than simply averaging the vectors of words that appear in each sentence, and facilitates the similarity detection for the algorithms [48]. We successfully identified factual evidence for 23% of the health-related information extracted from web pages, indicating the complexity inherent in health information. Further research is required to enhance contextual comparison between claims and verified references. Also, the cosine similarity outperformed the Jaccard distance measure for comparing the claims and evidence in this study, which is different from the previous study [4], as they reported that the Jaccard distance was better at the similarity selection measure. The reason may be due to differences in the nature of the datasets in the 2 studies.

XSL•FO
RenderX

Limitations

This study had several limitations. First, we faced a challenge in identifying sentences within the papers that closely matched the content of the web pages. Numerous methods have been devised to tackle this issue [19,43,46]; however, a comprehensive consideration of the complete meaning of sentences requires further investigation. In addition, 77% of the sentences did not have matching counterparts in the academic literature that we retrieved. Regarding this proportion, 2 possible assumptions can be made: either the sentences themselves were not valid or the algorithm was unable to locate their related counterparts. Another potential reason could be that the sentences, though addressing a common subject such as the same medical condition, exhibited variations in meaning or contextual interpretation. Consequently, it would be premature to assert that these unmatched sentences are inherently not credible, given the vast volume of published papers that renders comprehensive verification computationally infeasible. Expanding the number of selected papers for comparison could therefore increase the likelihood of identifying additional relevant sentences in the literature. Nonetheless, quantifying the proportion of credible sentences offers valuable insights to aid users in their trust assessment.

It is worth acknowledging that authors in the realm of health-related data often simplify and rephrase content to cater to their target audience, making it more challenging to identify credible references for their statements. Therefore, the researchers propose exploring other models such as text generation models as potential solutions to address this particular challenge including WordNet or sequence-to-sequence (Seq2Seq) models.

A second limitation was the sample size of the academic papers used in the comparison. Due to the extensive volume of health-related publications, the assessment was limited to a selection of 20 papers. Expanding this scope to include more papers per content type could enhance the discovery of factual evidence in PubMed publications. Thus, further investigation into paper retrieval approaches is recommended.

A third limitation was that, although the thematic categorization of web page content, such as epidemiology, semiology, and management, ensured that the generated PubMed queries were more precise and contextually relevant, the need for quality assessment of the extracted PubMed articles remains evident. While our method provides users with essential information to assess the accuracy of health information, the ultimate determination of its truthfulness may depend on individual judgment, expert evaluation, source credibility, scientific article quality (eg, journal quality, impact factor for the domain) and the contemporaneity of the information (eg, date of publication, retracted).

The retrieved articles may vary in quality, ranging from high-impact studies to potentially outdated or retracted articles that could influence the reliability of the fact-checking process and the conclusions drawn from matched content. Addressing these characteristics within an automated process remains a key challenge. In our previous research, the credibility of the sources was automatically assessed [29]. In this study, while we evaluate comparability with scientific articles, developing a credibility scoring strategy for these articles is also necessary. Combining an algorithm that evaluates website credibility and assigns a credibility score to scientific articles with 1 that determines truthfulness could significantly enhance the effectiveness of fact-checking. These models can change the structure of sentences and may improve the possibility of finding more similar sentences. Finally, while the process could not be automated entirely since each step needed human supervision for the results, the suggested techniques have the potential to substantially alleviate the human effort required to locate valid information.

Conclusions

Our approach aimed to empower users in the decision-making process regarding the truthfulness of information by providing relevant evidence and enabling informed judgments. As a pilot, this research serves as an initial step toward exploring the feasibility of automating fact-checking processes in health information. Specifically, the methods presented here could be applied to create tailored fact-checking workflows for specific disease areas, such as diabetes, arthritis, or cancer, which were among the categories included in this study. For instance, thematic categorization (eg, management and epidemiology) could improve the precision and relevance of fact-checking tools in health care contexts. Using state-of-the-art models such as transformers may improve the performance of the model since the BERT embedding captures the meaning of the sentences [49]. The investigation also revealed that incorporating PubMed publications as a trustworthy resource can enhance the discovery of similar credible information as evidence. Finally, while the process could not be entirely automated and required human supervision, the suggested techniques demonstrate significant potential for integration into fact-checking tools. This integration could reduce the effort required to validate health information, ultimately increasing accessibility and reliability for end-users. Future work should focus on expanding the dataset and testing the approach in real-world scenarios to further refine its applicability across various health domains.

Acknowledgments

The authors express their sincere gratitude to Factually Health Company for generously providing a factual dataset covering 7 diseases and to IVADO Labs for their support.

Abstract

Background: Detrimental effects of misinformation were observed during the COVID-19 pandemic. Presently, amid Russia's military aggression in Ukraine, another wave of misinformation is spreading on the web and impacting our daily lives, with many citizens and politicians embracing Russian propaganda narratives. Despite the lack of an objective connection between these 2 societal issues, anecdotal observations suggest that supporters of misinformation regarding COVID-19 (BM-C) have also adopted misinformation about the war in Ukraine (BM-U) while sharing similar media use patterns and political attitudes.

Objective: The aim of this study was to determine whether there is a link between respondents' endorsement of the 2 sets of misinformation narratives, and whether some of the selected factors (media use, political trust, vaccine hesitancy, and belief rigidity) are associated with both BM-C and BM-U.

Methods: We conducted a survey on a nationally representative sample of 1623 individuals in the Czech Republic. Spearman correlation analysis was performed to identify the relationship between BM-C and BM-U. In addition, multiple linear regression was used to determine associations between the examined factors and both sets of misinformation.

Results: We discovered that BM-C and BM-U were moderately correlated (Spearman ρ=0.57; *P*<.001). Furthermore, increased trust in Russia and decreased trust in the local government, public media, and Western allies of the Czech Republic predicted both BM-C and BM-U. Media use indicating frustration with and avoidance of public or mainstream media, consumption of alternative information sources, and participation in web-based discussions indicative of epistemic bubbles predicted beliefs in misinformation narratives. COVID-19 vaccine refusal predicted only BM-C but not BM-U. However, vaccine refusers were overrepresented in the BM-U supporters (64/161, 39.8%) and undecided (128/505, 25.3%) individuals. Both beliefs were associated with belief rigidity.

Conclusions: Our study provides empirical evidence that supporters of COVID-19 misinformation were susceptible to ideological misinformation aligning with Russian propaganda. Supporters of both sets of misinformation narratives were primarily linked by their shared trust or distrust in the same geopolitical actors and their distrust in the local government.

Introduction

During the COVID-19 pandemic, many countries worldwide have experienced an increase and acceleration in the spread of conspiracies, hoaxes, misinformation, and intentionally disseminated disinformation [1,2]. A large body of scientific research has demonstrated the detrimental effects of the infodemic on vaccine hesitancy worldwide [3,4], hateful and divisive rhetoric [5], politicization of the issue [6], and radicalization [7].

Social epistemic structures known as echo chambers, which primarily emerge in web-based communities where members reinforce their shared views while actively discrediting other relevant voices [8], have been frequently identified as primary digital channels reinforcing beliefs in misinformation and fueling radicalization [9,10]. Similarly, in the Czech Republic, misinformation narratives have been monitored in web-based communities [11], as well as in chain emails, that have been massively forwarded [12,13]. The main COVID-19 misinformation narratives encompassed a wide range of claims, including the pandemic being a hoax, the assertion that the virus is not dangerous or was artificially developed, and the belief that vaccines are harmful, while PCR tests, face masks, and other preventive measures against COVID-19 pandemic are ineffective [14].

Apart from the spread of misinformation—false information disseminated without the intent to deceive—fueled by the uncertainty of pandemic developments and negative emotions on social media [15], it has been suggested that the issue of COVID-19 pandemic has also been "hijacked" and used by disinformation campaigns conducted for monetary [16] or political purposes [17]. Previous studies have indicated that worries about the harmful effects of vaccination and distrust in Western pharmaceutical companies and politicians have been exploited and reinforced by Russian disinformation campaigns, aiming to undermine public support for state authorities [18]. The Czech Security Information Service reported that pro-Russian activists, promoting antivaccination attitudes and pro-Russian narratives, used COVID-19 pandemic as a useful topic for spreading conspiracies and disinformation [13]. These activists operated largely in symbiosis with the anti–COVID-19 measures movement, particularly on Czech language fringe news websites [13] labeled "disinformation" or "antisystem" websites by media experts [12].

Another massive wave of infodemic began to spread after the Russian invasion of Ukraine in February 2022 [19]. The war has become a new global threat, dominating media coverage and social media attention. Consequently, the focus on COVID-19 pandemic has receded, along with COVID-19 misinformation in the web-based environment [20]. In the Czech Republic, misinformation, including pro-Russian narratives about the conflict in Ukraine and hostile targeting Ukrainian refugees, has spread on "antisystem" websites [21]. These narratives also proliferated via chain emails, which have steeply increased in number after the invasion [20], in social media communities [22], as well as in web-based discussions under web news articles, where increased troll and bot activity has been observed [20,21]. A direct comparison of fact-checking publications revealed that while hoaxes related to both COVID-19 pandemic and the Ukraine war were predominantly disseminated via social media, they differed in their preferred format. Fabricated content was more common in pandemic-related hoaxes, whereas out-of-context images were prevalent in disinformation surrounding the Russia-Ukraine war [23]. The flood of web-based disinformation during both COVID-19 pandemic and the Russian invasion of Ukraine galvanized fact-checking and verification efforts [24-26].

While previous research has shown that individuals who believed in COVID-19 conspiracy theories were more prone to believe in other unrelated, broader conspiracies [27-29], it remains an open question whether those who believe in misinformation about COVID-19 pandemic are also more susceptible to believe politically ideological misinformation. This question has become pressing since the onset of the Russian invasion of Ukraine and the massive spread of disinformation aligned with Russian propaganda. Such disinformation mixes elements of strategic narratives rooted in historical revisionism, imperial mythology, and war memories with factual lies and misinterpretations, aiming to manipulate public opinion and influence political decisions in European Union (EU) and North Atlantic Treaty Organization (NATO) member states [30]. Comparisons have been drawn between the disinformation narratives related to COVID-19 pandemic and those related to the Russia-Ukraine war [14,23]. Anecdotal observations suggest that individuals sharing rigid beliefs in misinformation narratives about COVID-19 pandemic (BM-C) may have also adopted beliefs in misinformation about the Russian invasion of Ukraine (BM-U), and that they tend to use specific digital media channels while avoiding public and mainstream media and share antisystem attitudes and political orientation toward Russia [21]. However, no empirical research has examined this social phenomenon population-wide. Therefore, to validate or refute these observations, we conducted a nationwide representative cross-sectional survey of the Czech Republic.

The first aim of this study was to determine whether there is an association between respondents' endorsement of the 2 sets of misinformation narratives (BM-C and BM-U).

- Hypothesis 1: There is a correlation between BM-C and BM-U.

The second aim was to examine associations between beliefs in the 2 sets of misinformation (BM-C and BM-U) and factors anecdotally observed or suggested in both contexts. Media monitoring and official reports have indicated that both sets of misinformation have been spreading through specific digital

XSL•FO
RenderX

media channels, such as web-based discussions and web-based bubbles or echo chambers, political chain emails, and antisystem websites with political leanings toward Russia [13,21]. However, it remains unknown whether users of these channels are significantly more likely to believe the misinformation and to trust specific geopolitical powers on a nationwide scale. Therefore, we examined associations between (2a) political trust and the 2 sets of misinformation, as well as associations between (2b) media use factors and the 2 sets of misinformation.

- Hypothesis 2a: Distrust in the Czech government's decisions and public media, trust in Russia, and distrust in Russia's geopolitical opponents and Western allies of the Czech Republic (US, EU, and NATO) are shared factors that explain both BM-C and BM-U.
- Hypothesis 2b: The use of antisystem websites, emails, and social media as information sources, along with participation in web-based discussions and engagement in web-based bubbles, explains BM-C and BM-U.

The third aim of this study was to examine whether BM-C and BM-U are connected to COVID-19 vaccine refusal. Determining that this factor explains not only BM-C but also BM-U would indicate that this specific health-related behavior significantly reflects the politicization of the COVID-19 issue to such an extent that it increased susceptibility to ideological misinformation.

- Hypothesis 3: COVID-19 vaccine refusal explains both BM-C and BM-U.

In addition, we aimed to test whether beliefs in the 2 categories of misinformation are associated with belief rigidity. The underlying assumption is that individuals who endorse misinformation place greater emphasis on the importance of these beliefs, as they often provide complex collective narratives and transcend mere opinions on specific health, societal, or political issues. Rather, they may become a belief system infused with moral convictions, which tends to be fixed and rigid [31,32]. Belief rigidity has been connected to echo chambers [8,33], conspiracy thinking [34], and polarization [31,35,36].

- Hypothesis 4: Belief rigidity explains both BM-C and BM-U.

Methods

Procedure

The data were collected from April 25 to May 5, 2022, at the time when COVID-19 pandemic had subsided and 2 months after the start of the Russian invasion of Ukraine. The cross-sectional survey was completed by members of the Czech National Panel [37] as a part of a longitudinal study [38], using the standardized computer-assisted web interviewing method. Participation was voluntary, with financial compensation. The mean completion time of the survey was approximately 11 minutes, and participants were informed in advance about the length. The survey included sociodemographic data (gender, age, level of education, region of residence, and household income), as well as questions about beliefs in misinformation regarding COVID-19 pandemic and the Russian invasion of Ukraine, media use, political trust, belief rigidity, and whether and how many times they have been vaccinated against COVID-19. Only self-reported measures were used. To ensure the protection of personal information, all collected data were securely stored in an encrypted, password-protected institutional database hosted on National Institute of Mental Health servers. Only authorized personnel had access to the data. Any personal identifiers were anonymized during data processing to prevent unauthorized access or identification of participants.

Participants

Participants of the longitudinal study [38] were invited to participate in this study. We received responses from 1623 respondents (return rate: 55% of 2950 invited; 839/1623, 51.7% women) aged between 20 and 91 years (mean 55.04, SD 15.55). The proportions of participants' attained educational levels were as follows: 4.6% (76/1623) elementary school education, 29.1% (472/1623) certificate of apprenticeship, 36.2% (587/1623) high school education, and 30.2% (490/1623) university degree. The sample was constructed to be quota-representative of the adult population of the Czech Republic. To ensure repeated participation of various sociodemographic groups, it was necessary to adjust the current sample through poststratification weighting. This adjustment was based on current population distributions (using data from the Czech Statistical Office) for the following characteristics: gender, age, education, size of place of residence, region, crosscutting of age and education, crosscutting of age and gender, and employment status. The inclusion criteria were knowledge of the Czech language and being older than 18 years.

Measures

Beliefs in Misinformation Narratives

To measure BM-C and BM-U, we developed 2 questionnaires. The questionnaires were constructed based on the main misinformation related to COVID-19 published by the Center Against Hybrid Threats within the Ministry of the Interior of the Czech Republic [39]. The Ministry reported that such narratives had been spread in an attempt to exploit societal issues in accordance with the interests of foreign powers. We reduced the number of items from the original 15 to 6 based on results from our pilot study (N=423), excluding items according to item analysis, exploratory factor analysis (EFA), and the results of the Cronbach α coefficient. BM-C items are shown in Textbox 1. Similarly, the BM-U questionnaire was constructed, using the prevalent misinformation narratives related to the Russian invasion in Ukraine at the time of the study [40]. We selected 4 items from the original 8 based on pilot data according to the same procedure as in BM-C. BM-U items are shown in Textbox 1. Both questionnaires showed good internal consistency in both the pilot study (BM-C: Cronbach α=0.953; BM-U: Cronbach α=0.932) and in this study (BM-C: Cronbach α=0.846; BM-U: Cronbach α=0.891). Participants rated the items on a 5-point scale (1: "I do not agree at all"—5: "I completely agree").

XSL•FO
RenderX

Textbox 1. Items for beliefs in misinformation narratives (beliefs in misinformation narratives about COVID-19 pandemic [BM-C] and beliefs in misinformation about the Russian invasion of Ukraine [BM-U]).

Evaluate the extent to which you agree or disagree with the following statements.

BM-C

- "Western pharmacological vaccine companies are untrustworthy."
- "Vaccines are dangerous for the vaccinated."
- "The discrimination against Russian and Chinese vaccines is largely driven by political reasons."
- "The coronavirus was developed artificially, perhaps as a biological weapon."
- "The epidemic is fake, the situation has never been so serious."
- "Epidemic measures were ineffective and were counterproductive."

BM-U

- "The demilitarisation and de-Nazification of Ukraine is a legitimate objective for the Russian military operation in Ukraine."
- "The civilian casualties on the Ukrainian side are deliberately exaggerated by the European media."
- "Ukraine is developing banned biological weapons on its territory."
- "NATO and Western countries are exploiting Ukraine to serve their own interests."

COVID-19 Vaccination

Participants were asked whether and how many times they had been vaccinated against COVID-19 (0, 1, 2, or 3 times). It should be noted that at the time of the survey, the Ministry of Health of the Czech Republic recommended 3 doses of the vaccine.

Media Use

We used an adapted version of the media use questionnaire [41]. We omitted some items and included additional ones, while also rewording some items to better suit the research objectives of measuring media behavior and media effects that may be indicative of or contribute to the spread of misinformation. To compare responses to the 2 societal issues, we used identical wording for questions related to the COVID-19 pandemic (C), and the Russian invasion of Ukraine (U), with only a difference in the topic and time frame being questioned (eg, "How often did you search for news regarding COVID-19 at the height of the pandemic?" or "How often did you search for news on the Russian invasion of Ukraine last month?"). The mirrored items were placed in different locations within the questionnaire and never in sequence. The newly developed measures were tested in a pilot survey conducted via Facebook in April 2022 (N=423; response rate: 51.8% of 817 invited). Respondents were asked about their frequency of use of media channels categorized as public media, mainstream news websites [42], and those that have been previously connected to spreading misinformation: emails as a source of information (possibly indicating political chain emails), YouTube, social media, and "anti-system websites" that have been identified as such by various media experts [12,42]. However, at the time of our survey, in reaction to the Russian invasion of Ukraine and the uncertain development of the situation, most of the antisystem websites were evaluated as a threat to national security and were officially banned in the Czech Republic due to their open promotion of Russian disinformation narratives. Only 1 functioning, moderate news website, remained in our survey. Participants were also asked about their engagement in web-based discussions and web-based bubbles related to C/U. Furthermore, we decided to examine several other aspects of media use—searching and sharing the news (C/U), respondents' interest in the 2 topics (C/U), and their frustration with public and mainstream media.

Political Trust

Perceptions of trust in the (1) Czech government and (2) public media were assessed in relation to both issues (C/U). Due to the high correlation of items 1 (C) and 2 (C) (r=0.783, n=1623; P<.001), as well as items 1 (U) and 2 (U) (r=0.849, n=1623; P<.001), we summed the items in 1 score for each topic: trust in the Czech government and public media regarding COVID-19 (*Trust in CZ-C*); trust in the Czech government and public media regarding Russian invasion of Ukraine (*Trust in CZ-U*). In addition, distrust in foreign geopolitical actors (Russia, United States, China, EU, and NATO) and belief rigidity was assessed. Detailed descriptions of the survey items and response scales for media use, political trust, and belief rigidity are shown in Multimedia Appendix 1.

Statistical Analysis

All data were analyzed using R software (R Core Team). The significance level was set at P≤.05. Poststratification weighting was applied using a quadratic programming algorithm based on current population distributions of the following characteristics: gender, age, education, region, residence size, job status, interaction between age and education, and interaction between age and gender. Descriptive statistics were used for demographic description. Shapiro-Wilk test did not confirm the normal distribution of BM-C and BM-U. EFA was conducted on both BM-C and BM-U items to uncover the latent structure based on interdependence between the items. The primary aim of the EFA was to clearly differentiate COVID-related and ideological items, ensuring that the correlation between BM-C and BM-U scales is not influenced by the ideological items possibly present in BM-C.

XSL•FO
RenderX

As the data were nonparametric, we used Spearman correlation to determine the relationship between BM-C and BM-U (Hypothesis 1). Multiple linear regression models were used to reveal the relationships between the examined factors according to Hypotheses 2-4 (COVID-19 vaccine refusal, media use, political trust, and belief rigidity) and beliefs in BM-C and BM-U. For the multiple linear regression models, we used normalization of nonparametric right-skewed data by square root. Two distinct models were constructed, 1 for BM-C and 1 for BM-U (dependent variables), with COVID-19 vaccine refusal, media use, political trust, and belief rigidity as independent variables. We also controlled for demographic characteristics (age, gender, education, and income). To compare the predictive power of the independent variables, we used a feature scaling approach. Specifically, we used normalization to standardize all continuous input variables to a uniform range of 1-5. This step guarantees comparability and stability in the regression analysis, establishing a standardized input space for the model and enabling the evaluation of the effect of each variable. However, categorical variables were maintained in their original scale to preserve their interpretability and intrinsic categorical distinctions.

Ethical Considerations

The procedure performed in this study was in accordance with the ethical standards of the institutional research committee and with the 1964 Helsinki Declaration and its later amendments. The study was approved by the ethics committee of the National Institute of Mental Health, Czech Republic (reference no. 181/21). The data were anonymized. Respondents were compensated by the Czech National Panel at a standard rate of 1 CZK (US $0.041) per minute for completing the questionnaire. The compensation was provided as credit, which could be transferred to a bank account, redeemed for a material reward, or donated to charity. In addition, 2 randomly selected participants had the chance to win a tablet. All participants provided informed consent. They were informed about the purpose of the study. Furthermore, they were informed that the data would be accessible only to authorized research staff and the principal investigator, whose name and contact information were provided for any follow-up questions or concerns. Participants were assured that their participation was voluntary.

Results

Exploratory Factor Analysis

EFA was conducted using parallel analysis to identify the underlying structure of the BM-C and BM-U items. Two factors were extracted, explaining 58.7% of the total variance, with factor 1 accounting for 32.4% of the variance and factor 2 accounting for 26.3%. The overall Kaiser-Meyer-Olkin measure of sampling adequacy was 0.91, indicating that the data were highly suitable for factor analysis. The Bartlett sphericity test (χ^2_{45}=9338; *P*<.001) further confirmed the appropriateness of conducting EFA. An Oblimin rotation was applied to enhance interpretability, allowing for correlations between factors. The first factor, labeled “Ideological,” included all BM-U items and BM-C item 3 (“The discrimination against Russian and Chinese vaccines is largely driven by political reasons”). The second factor, labeled “COVID,” comprised all remaining BM-C items (except item 3). Due to its significant loading on the ideological factor and theoretical considerations, BM-C item 3 was excluded from further analysis. Factor loadings are shown in Multimedia Appendix 2.

Correlation Between BM-C and BM-U and Descriptive Statistics for BM-C and BM-U

A moderate positive correlation was found between BM-C and BM-U (Spearman ρ=0.57; *P*<.001). For a more straightforward description of BM-C and BM-U, we considered 4 points (“I rather agree”) and 5 points (“I completely agree”) as an indication of belief in misinformation (*supporters*). Those who rated 3 points (“I neither agree nor disagree”) were considered undecided whether they believe in misinformation or not (*undecided*). Those who rated 1 (“I completely disagree”) or 2 (“I rather disagree”) were considered *opponents* who do not endorse misinformation narratives. According to this grouping based on cumulative scores, the prevalence of BM-C supporters was 13.4% (217/1623), and the prevalence of BM-U supporters was 9.9% (161/1623). There were 50% (812/1623) of undecided respondents for BM-C and 31.1% (505/1623) for BM-U. The demographic description showed that supporters in BM-C were most represented in apprenticeship education degree (88/217, 41%), followed by high school degree (77/217, 36%) and university education level (42/217, 19%), with lowest numbers in elementary education level (10/217, 5%). BM-C opponents were most prevalent in the university education level (243/594, 40.9%). Supporters of BM-U were most prevalent in apprenticeship education level (60/505, 37%), followed by high school degree (54/161, 34%) and university degree (39/141, 24%). BM-U opponents were most prevalent in high school (357/957, 37.3%) and university education (342/957, 35.7%), followed by apprenticeship education (223/957, 23.3%). Overall, supporters and undecided both for BM-C and BM-C were less prevalent in the university education level and more in the apprenticeship education level compared with nonsupporters. Regarding household income, supporters and undecided (both for BM-C and BM-C) were represented less in the high-income group and more in the below poverty line income group compared with opponents. In terms of gender, noticeable differences were found in the undecided groups, particularly in BM-U, with female participants representing a higher proportion (304/505, 60.2%). Conversely, male participants were more prevalent among BM-U supporters (98/161, 61%). Differences in age compared with an average of the whole sample (mean 55.04, SD 15.56) were observed only in BM-U supporters, who were older (60.9 years), and BM-U opponents, who were younger (49.3 years). Vaccine refusers were minimally represented in BM-C opponents (33/594, 6%), more in BM-C undecided (146/812, 18%), and most in BM-C supporters (142/217, 65%). Moreover, 34.6% (75/217) of BM-C supporters were vaccinated despite their beliefs. Regarding BM-U, vaccine refusers were most represented in BM-U supporters (64/161, 40%), followed by BM-U undecided (128/505, 25.3%), with the lowest numbers in BM-U opponents (129/957, 13.5%; Figure 1). The descriptive statistics are shown in Table 1.

variable (Table 2). Trust in the Czech government and public media, vaccination against COVID-19 pandemic, distrust in Russia, searching for news on COVID-19 pandemic, and participation in web-based discussions predicted lower levels of BM-C. Distrust in the United States, distrust in the EU, frustration from public and mainstream news, rigid beliefs, use of emails as a source of information, sharing COVID-19 news, and engagement in web-based bubbles predicted higher levels of BM-C. Regarding demographic factors, upper middle income (compared with high income), as well as elementary, apprenticeship, and high school education levels (compared with university education level) were associated with increased BM-C. The below poverty line income group (compared with high income) predicted lower levels of BM-C.

Factors Explaining BM-U

The multiple regression model explained 62.21% of the variance in BM-U ($F_{30,1591}$=90.01; adjusted R^2=0.62; P<.001). Descriptions of variables used in the BM-U model are shown in Multimedia Appendix 3. We found significant relationships between the 12 examined factors as independent variables and BM-U total score as the dependent variable (Table 2). Trust in the Czech government and public media, distrust in Russia, consumption of mainstream news websites, and searching for news about the war in Ukraine predicted lower levels of BM-U. Conversely, distrust in the United States, distrust in the EU, frustration from public and mainstream news, consumption of "antisystem websites," use of emails as a source of information, use of social media as an information source, reading discussions under web news articles, and belief rigidity predicted higher levels of BM-U. Regarding demographic factors, below poverty line income (compared with high income), elementary education level (compared with university education level), and older age were associated with higher levels of BM-U.

Discussion

Principal Findings

Our study provides evidence of a connection between beliefs in COVID-19 misinformation (BM-C) and misinformation regarding the Russian invasion of Ukraine (BM-U) by identifying a correlation between these 2 sets of beliefs and several shared factors. Regarding political trust, higher trust in Russia and lower trust in local government, public media, and Western allies of the Czech Republic (the EU and the United States) were revealed as strong predictors of both BM-C and BM-U. In addition, frustration with public and mainstream media, using emails as a source of information—possibly indicating chain emails—and reduced frequency in searching for news related to COVID-19 pandemic or war in Ukraine, predicted both BM-C and BM-U. We also identified media use patterns commonly associated with the spread of misinformation, which predicted either BM-C or BM-U. These included participation in web-based bubbles, engagement in discussions under web news articles, use of antisystem websites, avoidance of mainstream media, use of social media as an information source, and sharing news. In addition, belief rigidity was a significant predictor for both BM-C and BM-U.

Correlation Between BM-C and BM-U

A moderate positive correlation discovered between BM-C and BM-U supports our hypothesis, indicating that a significant number of individuals believing in COVID-19 misinformation have also adopted ideological misinformation regarding the Russian invasion of Ukraine. This extends previous findings that beliefs in COVID-19 conspiracies correlate with beliefs in other, broader and unrelated conspiracies [27,28] to the politicized side of COVID-19 misinformation, which increased susceptibility to ideological misinformation aligning with Russian propaganda. Our finding provides further evidence for the so-called "conspiracy singularity" [43] suggesting the tendency of actors to spread and interconnect various conspiracy theories [44,45]. For instance, the same actors who spread COVID-19 conspiracies before the Russian invasion of Ukraine later disseminated anti-NATO and pro-Russian narratives in Finland [46] and Slovakia [47]. Our findings thus corroborate similar phenomena observed beyond the context of the Czech Republic and may provide further insights into the mechanisms by identifying underlying factors revealed in our analyses, which are discussed in the sections "Associations of Political Trust and Beliefs in Misinformation," "Associations of Media Use and Beliefs in Misinformation Narratives," "COVID-19 Vaccine Refusal," and "Belief Rigidity."

Associations of Political Trust and Beliefs in Misinformation

Our finding that lowered trust in governmental decisions and public media was associated with both increased BM-C and BM-U supported our hypothesis. Moreover, it was the strongest predictor explaining both BM-C and BM-U. It is in line with previous research linking distrust in public institutions to COVID-19 misinformation beliefs [48-51]. While most previous findings on associations between beliefs in COVID-19 misinformation and political attitudes report that conservatism is associated with increased susceptibility to misinformation [52-54], we did not inquire about partisanship but rather about trust in geopolitical powers. Our results showing increased trust in Russia in higher levels of both BM-C and BM-U indicate a leaning toward this geopolitical power in supporters of both sets of misinformation. In addition, we observed increased distrust toward the Czech Republic's geopolitical allies and Russia's main opponents—the United States and the EU—among individuals with higher levels of both BM-C and BM-U. While this ideological inclination is not surprising regarding BM-U, which openly promotes Russian propaganda, it is not as readily apparent in the case of BM-C. However, our result aligns with previous research that has suggested the role of Russian disinformation campaigns in supporting the antivaccination movement [18,55,56].

Our findings can thus be contextualized in light of the goals of Russia's hybrid war strategy, which aims to continually undermine the trustworthiness and legitimacy of foreign governments in the eyes of the target population by warping their beliefs, thoughts, decisions, and behavior over the long term [57]. The goal of this tactic is to gradually reconstruct the target population's prior beliefs in favor of Russia [58,59]. However, our study cannot establish a causal relationship in terms of direct influence of Russia's disinformation campaigns. The inclination toward Russia may also have deep historical roots, as the Czech Republic—former Czechoslovakia—was part of the Eastern Bloc under the direct influence of the Soviet Union for 4 decades. Increased trust in Russia may also represent an alternative to the current Western orientation of the Czech Republic as a member of the EU and NATO, reflecting a broader, socially driven epistemic mistrust that manifests in the rejection of authoritative information, as suggested by the socioepistemic model of belief in conspiracy theories [60].

Associations of Media Use and Beliefs in Misinformation Narratives

All of the identified media use factors linked to either BM-C or BM-U provided support for our hypothesis regarding media

XSL•FO
RenderX

use, formulated based on previous observations and theoretical or empirical associations with the dissemination of misinformation. However, it is noteworthy that not all of the examined factors demonstrated significant relationships with both BM-C and BM-U. The strongest media factor associated with higher levels of both beliefs was identified as frustration with the public and mainstream media. While previous research has established this factor as a predictor of higher anxiety and depression levels during the COVID-19 pandemic [41], our study extends its relevance to the context of misinformation susceptibility. This observation is complemented by another finding, which links less frequent searches for COVID-19 news with higher BM-C levels, and less frequent consumption of mainstream media and searches for the news about the war in Ukraine with BM-U. These findings align with previous research [1,61,62] and suggest that supporters of misinformation narratives engage in avoidance behavior, possibly due to their mistrust in information they perceive as misrepresented in public and mainstream media.

On the other hand, supporters of BM-C and BM-U showed higher engagement with other media channels. Specifically, there was an association between obtaining news information from emails—possibly indicating chain emails—and both BM-C and BM-U. In addition, reading discussions under web news articles and consuming information from antisystem websites was positively associated with BM-U. These findings corroborate observations regarding the role of such media channels in disseminating misinformation content and the susceptibility of their consumers to misinformation [13,20].

Next, the positive relationship between obtaining information from social media and increased BM-U, as well as the association between engagement in web-based bubbles and increased BM-C, indicates that the social media environment contributed to the spread of misinformation and their users' endorsement, as suggested by previous research [1,51,63-66]. While we acknowledge the limitations of the web-based survey method in assessing the phenomenon of web-based (epistemic) bubbles or echo chambers, it is plausible to assume that this phenomenon may have indeed been reflected in our results, as it aligns with prior findings [8-10,64].

Conversely, the negative relationship of engagement in discussions on social media and BM-C, as well as the lack of discernable associations between cumulative exposure to social media and BM-C/BM-U, underscores the reductive conclusions of associating social media platforms solely with the spread of misinformation. Indeed, social media offers users engagement in socializing and discussing a diverse array of content, as well as a broad spectrum of viewpoints on sociopolitical issues. Notably, in the context of nondemocratic regimes, digital media often serves as a primary source of obtaining reliable information. Research in nondemocratic regimes indicates that the use of digital media correlates with diminished adherence to misinformation, contrasting with users reliant solely on official information channels [67].

Our next finding of a positive association between sharing news and heightened levels of BM-C indicates that BM-C supporters demonstrated a propensity for active engagement with digital media. Speculatively, this could be due to heightened arousal triggered by specific content, frustration, or a sense of moral obligation to disseminate the alternative information on social media, perceived as accurate, compared with information reported by public and mainstream media, perceived as misleading or incomplete [68]. This inference is drawn from previous research indicating that the perceived accuracy of content significantly influences the likelihood of its sharing by users [69]. While our study did not directly explore the specific content shared by respondents, it is pertinent to note that previous studies have demonstrated that misinformation tends to be inherently more frequently shared than other types of news [69].

COVID-19 Vaccine Refusal

Our finding that vaccine refusal was a strong factor associated with BM-C supports our hypothesis and aligns with extensive prior research linking exposure to COVID-19 misinformation to COVID-19 vaccine hesitancy [48,62,70-73]. Our finding provides further evidence that COVID-19 vaccine refusal is a behavioral indicator of diverse attitudes that transcend medical concerns. However, it is important to note that 34.6% of BM-C supporters (75/217) reported being vaccinated, indicating a divergence from their beliefs. They may ultimately yield to social pressure and decide to get vaccinated, considering the practical difficulties posed by remaining unvaccinated in their daily lives during the pandemic.

Contrary to our hypothesis, COVID-19 vaccine refusal was not associated with BM-U, suggesting that this health-related behavior is a broader phenomenon that includes vaccine hesitancy due to health reasons, medical concerns, simple reluctance, and other factors. We conclude that vaccine refusal should not lead to the reductionist conclusion that COVID-19 vaccination was entirely politicized. However, we observed a higher prevalence of vaccine refusers in BM-U supporters (64/161, 39.8%), followed by BM-U undecided (128/505, 25.3%), with the lowest numbers in BM-U opponents (129/957, 13.5%). Special attention should be given to the BM-U undecided group, requiring longitudinal monitoring to assess whether they might become new adherents of BM-U.

Belief Rigidity

Our additional finding of a positive association between the rigidity of one's beliefs regarding sociopolitical issues with both BM-C and BM-U indicates that those who adhere to the alternative interpretations of both sociopolitical issues tend to harbor more fixed and rigid opinions than those who do not support such interpretations. Our finding is consistent with previous studies connecting belief rigidity to conspiratorial thinking [34] and beliefs in misinformation propagated through social media [74]. Rigid beliefs have been found to facilitate group cohesion, partisanship, polarization, and extremism [31,35,75]. It is thus plausible that beliefs such as BM-C or BM-U may serve as a group-shared alternative "truth" while being shared through the digital media environment as identified in our analysis. Furthermore, it is in line with our other finding (discussed in the "Associations of Media Use and Beliefs in Misinformation Narratives" section) indicating avoidance of public and mainstream information sources. This pattern is

XSL•FO
RenderX

consistent with previous research suggesting that belief rigidity is strengthened when individuals isolate themselves from contradictory information, thus reinforcing their confirmation bias [10].

Conclusions

Our findings support the hypothesis that individuals who endorsed COVID-19 misinformation were more susceptible to ideological misinformation, aligning with Russian propaganda. Supporters of both misinformation narratives shared common traits, including heightened distrust of local government, public media, the United States, and the EU, along with increased trust toward Russia. They also exhibited increased belief rigidity and demonstrated several common media use patterns, previously linked to the spread of misinformation. To gain a deeper understanding of these phenomena, longitudinal monitoring is essential. By tracking the development of BM-C, BM-U, and the examined factors over time, causal relationships can be uncovered.

Limitations

The primary shortcoming of this study was the constraint imposed by the short survey format. Due to time limitations, it was not feasible to use longer standardized questionnaires such as the Belief Rigidity Scale. Instead, we opted for a single statement specifically related to societal issues, such as politics, war, and pandemics, and we considered this finding as supplementary. On the other hand, we chose to investigate media use in more detail with practical implications in mind, aiming to identify specific media channels where misinformation is prevalent for targeted recommendations. However, some aspects of the media environment, such as web-based communities with an echo chamber effect and chain emails, were challenging to assess via survey. Consequently, our findings regarding these information sources should be interpreted with caution. In addition, while we acknowledge the availability of standardized COVID-19 conspiracy or misinformation scales, our objective was to study COVID-19 misinformation prevalent in the local context of the Czech Republic as identified by previous analytical sources.

Acknowledgments

The authors thank colleagues from PAQ Research, especially Daniel Prokop, for the opportunity to participate in their panel research and sharing sociological data, and Michaela Röschová for her valuable assistance with the technical aspects of the survey and data management. This work was supported by Czech Science Foundation (grant no. 20-13458S) and Ministry of Health of the Czech Republic (grant NU22-D-132).

Data Availability

The dataset generated during this study is available in the OSF data repository (osf.io/wtuqj).

Conflicts of Interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Abstract

Background: The COVID-19 pandemic has been accompanied by an unprecedented infodemic characterized by the widespread dissemination of misinformation. Globally, misinformation about COVID-19 has led to polarized beliefs and behaviors, including vaccine hesitancy, rejection of governmental authorities' recommendations, and distrust in health institutions. Thus, understanding the prevalence and drivers of misinformation is critical for designing effective and contextualized public health strategies.

Objective: On the basis of a tailored survey on health misinformation, this study aims to assess the prevalence and distribution of COVID-19–related misinformation in Spain; identify population groups based on their beliefs; and explore the social, economic, ideological, and media use factors associated with susceptibility to misinformation.

Methods: A cross-sectional telephone survey was conducted with a nationally representative sample of 2200 individuals in Spain. The study developed the COVID-19 Misinformation Scale to measure beliefs in misinformation. Exploratory factor analysis identified key misinformation topics, and k-means clustering classified participants into 3 groups: convinced, hesitant, and skeptical. Multinomial logistic regression was used to explore associations between misinformation beliefs and demographic, social, and health-related variables.

Results: Three population groups were identified: convinced (1078/2200, 49%), hesitant (666/2200, 30.27%), and skeptical (456/2200, 20.73%). Conspiracy theories, doubts about vaccines, and stories about sudden death emerged as the most endorsed current misinformation topics. Higher susceptibility to misinformation was associated with the female sex, lower socioeconomic status, use of low-quality information sources, higher levels of media sharing, greater religiosity, distrust of institutions, and extreme and unstated political ideologies. Frequent sharing of health information on social networks was also associated with membership in the skeptical group, regardless of whether the information was verified. Interestingly, women were prone to COVID-19 skepticism, a finding that warranted further research to understand the gender-specific factors driving vulnerability

XSL•FO
RenderX

to health misinformation. In addition, a geographic distribution of hesitant and skeptical groups was observed that coincides with the so-called empty Spain, areas where political disaffection with the main political parties is greater.

Conclusions: This study highlights the important role of determinants of susceptibility to COVID-19 misinformation that go beyond purely socioeconomic and ideological factors. Although these factors are relevant in explaining the social reproduction of this phenomenon, some determinants are linked to the use of social media (ie, searching and sharing of alternative health information) and probably the political disaffection of citizens who have stopped believing in both the ideologically centrist mainstream parties and the institutions that represent them. Furthermore, by establishing the profile and geographic distribution of the convinced, hesitant, and skeptical groups, our results provide useful insights for public health interventions. Specific strategies should focus on restoring institutional trust, promoting reliable sources of information, and addressing structural drivers of health misinformation linked to gender inequalities.

Introduction

Background

The COVID-19 pandemic has not only posed unprecedented challenges to global public health but also has been accompanied by a pervasive infodemic [1,2]. This term, defined by the World Health Organization (WHO) as "an over-abundance of information—some accurate and some not—that makes it hard for people to find trustworthy sources and reliable guidance when they need it" [3], underscores the critical role of information in shaping public responses to social and health emergencies [4]. While access to information is essential, the unprecedented volumes of data surrounding SARS-CoV-2 and COVID-19 has made it increasingly difficult for individuals and institutions to discern scientific evidence from misinformation or disinformation and anecdotal claims [5]. In fact, in this context of global uncertainty, we have been able to observe speculations and conspiracy theories [6] related to different topics, such as the supposed effectiveness of the RNA vaccines, the hidden intentions of global leaders and the pharmaceutical industry, false health treatments (eg, the hydroxychloroquine case), the real origin of the new virus, and even doubts about the existence of the virus [7].

During the recent pandemic, the dissemination of false information about scientific and health-related matters spread faster and more easily than the virus itself [8]. Furthermore, the blurring boundaries between evidence-based knowledge and false or misleading information linked to the new disease introduced substantial complexities to the population's ability to make informed decisions [5]. Specifically, the dissemination of new health guidelines and the heterogeneous political measures to contain the pandemic through traditional and social media caused an excess of noise around everything related to health (ie, vaccines, treatments, contention measures, etc), which ended up generating social polarization and social divisions that made it difficult to manage and control the health emergency situation [9]. In addition, information overload contributed to cognitive fatigue, which has also been shown to reduce people's ability to critically evaluate health sources and content [10]. In addition, the role of influential opinion and political leaders has further exacerbated the situation [11], propagating misconceptions and encouraging risky behaviors that may have undermined public health interventions [12].

The COVID-19 infodemic exemplifies how modern information ecosystems, particularly those based on social media communication, can amplify both evidence-based guidance and misinformation at an unprecedented scale [13,14]. These "misinformation ecosystems" have directly influenced social and health behaviors, contributing to vaccine hesitancy [15,16], noncompliance with health measures [17], and the proliferation of pseudoscientific remedies and theories [18], ultimately challenging the effectiveness of governmental and institutional countermeasures [19]. Moreover, as recent studies have shown, scientific content and sources also play a relevant role in the dissemination of misinformation, for example, through the design of poorly elaborated messages via social media platforms or the provision of weak evidence [20]. Therefore, when focusing on the concept of misinformation in health and, specifically, COVID-19, we are faced with a cross-cutting phenomenon that permeates all strata of our societies.

While it is becoming increasingly common to find studies addressing health misinformation and its impact on health systems, it still remains a difficult concept to define due to the fluctuating nature of the social media ecosystem and the diversity of health-related topics it covers, especially when analyzing the subject matter of COVID-19 [21]. To address this complexity, in this study, we adopt a broad definition of health misinformation, encompassing any health-related claim that relies on anecdotal evidence, is false, or is misleading due to the absence of scientific confirmation [22], regardless of whether this information has been issued intentionally or unintentionally [23]. Therefore, our definition incorporates 2 key forms: misinformation, which refers to false information shared without an intent to cause harm [24,25], and disinformation or malinformation, which involves false or partially true information deliberately crafted to deceive or harm specific individuals, social groups, institutions, or nations [26]. Our definition implicitly incorporates the flexibility of the definition by the National Academies of Sciences, Engineering, and Medicine report, which defines science-related misinformation as "information that asserts or implies claims that are inconsistent with the weight of accepted scientific evidence at

XSL•FO
RenderX

the time." This conceptualization underscores the importance of distinguishing between misinformation that directly contradicts well-established evidence and misinformation that may reflect evolving or uncertain scientific consensus. In light of this, our study attempts to capture both types of claims in the COVID-19 context, acknowledging that the epistemic status of some items may be more contentious than others [27].

Although studies have been emerging since the beginning of the COVID-19 pandemic that have addressed misinformation sources, channels, and messages [28-31], in general, less attention has been paid to the exhaustive characterization of the profiles of people who embrace misinformation and particularly understanding which messages have penetrated the audiences. In the literature, cross-sectional studies can be found that have usually used opportunistic samples to understand specific attitudes and behaviors (eg, related to the new vaccines or preventive measures) [32-37], but, to our knowledge, there are no exhaustive and updated studies that allow us to determine the current prevalence of COVID-19 misinformation about the beliefs that may have emerged in recent years and that have progressively taken root in public opinion (eg, doubts about the need for additional vaccines, the origin of the virus, the existence of hidden governmental plans, and sudden deaths, among others). In addition, this highlights the need to provide a comprehensive sociodemographic and contextualized description of these social groups, which could ultimately help us identify the groups that we should target with information campaigns aimed at increasing literacy in COVID-19–related health issues.

In a recent review, political orientation has been found to be a key predictor of misinformation and beliefs in fake news [9]. However, most of the studies reviewed were based in the United States, reflecting a limited geographical focus. To date, this association has not been systematically explored in other contexts, underscoring the need for context-specific research to better understand how political orientation influences susceptibility to misinformation within different sociopolitical frameworks. Particularly in the Spanish case, a study has been carried out analyzing conspiracy beliefs and their association with ideological and religious values based on survey data from the Spanish Foundation for Science and Technology; however, the dataset is not specifically focused on the study of health misinformation related to COVID-19 but on the scientific aspects related to the pandemic [38]. Moreover, although there have been attempts to identify the diversity of misinformation and conspiracy groups through the application of latent profile techniques [39], there is still a lack of comprehensive characterizations of the explanatory factors (demographic, social, economic, political, and media use) of population profiles susceptible to misinformation. In other words, in addition to characterizing the sociodemographic groups of the different profiles that embrace health misinformation, there is a need for studies that provide detailed information on how these groups consume and share information as well as other health aspects that could explain their positioning (eg, general health status, chronic conditions, diagnoses, and COVID-19 vaccination).

Objectives

Given these knowledge gaps, the aim of this exploratory study was to assess the prevalence and distribution of COVID-19–related misinformation in Spain using data from a representative population sample obtained from the DCODES (Collective dynamics of health opinion contagion: the COVID-19 infodemic and its effects on decision making processes) project. Specifically, we aim to achieve the following specific objectives: (1) identify the issues that generate the greatest social division around the COVID-19 pandemic, (2) classify the main groups around these issues of misinformation about COVID-19, and (3) describe these social profiles by studying the association with a broad set of social determinants that could explain the positioning of these groups.

Methods

Design and Setting

This study used a cross-sectional design using telephone surveys conducted from January 2024 to March 2024, targeting individuals aged >18 years residing in Spain. Participants were selected from available databases, with consent obtained before their participation. The telephone survey method was chosen due to its numerous advantages, making it particularly suited to this study's objectives. First, it allowed for rapid and extensive access to participants, including those in remote or rural areas. Second, it was cost-effective compared to face-to-face interviews, reducing logistical expenses. Third, the standardized administration of questionnaires minimized interviewer-related variability, ensuring greater consistency in data collection. Fourth, it was convenient for respondents, who could complete the survey from their homes, facilitating higher participation rates. Fifth, telephone surveys were particularly effective for addressing sensitive topics, as respondents often felt more secure and perceived greater confidentiality in such interactions. Collectively, these features made telephone surveys an optimal data collection method, ensuring both broad representativeness and logistical feasibility in this study.

Stratified sampling guaranteed representativeness from the different geographic areas of the country based on key demographic factors: age, sex, region, and population size of the areas of residence. Using a multistage sampling approach and drawing on nationally representative datasets, a sampling frame reflecting the demographic composition of Spain was composed. This rigorous methodology minimized selection bias and allowed accurate conclusions to be drawn. The final sample composed of 2200 individuals, with a confidence level of 95% and an estimated error of +2.1 or –2.1 percentage points.

This survey was part of the DCODES project, which aimed to conduct an in-depth analysis of the determinants of misinformation during the COVID-19 pandemic.

Measures

The questionnaire was developed by a team of 6 researchers with experience in survey methods and misinformation studies through 3 nominal group meetings in which the main contents and variables potentially associated with misinformation on COVID-19 were discussed and consensus was reached on which

XSL•FO
RenderX

were the most relevant in the general population. The questionnaire was divided into 4 fundamental blocks of indicators (Table 1).

Table 1. Thematic blocks and description of indicators.

Variables	Description of measures
COVID-19 misinformation indicators	The primary set of indicators included the COVID-19 Misinformation Scale, with 12 items related to erroneous, false, or misleading topics that were currently most widely disseminated about COVID-19. These items were extracted from the 3 main platforms for checking hoaxes and fake news in Spain (Newtral, Maldita.es, and EFE Verifica, belonging to the International Fact Checking Network). These indicators were presented on a Likert scale from 1 (totally disagree) to 5 (totally agree) points. The 12 items had high internal consistency (Cronbach α=0.87). The content of each statement is available in the Results section.
Health information use, media sharing, and digital health literacy	The survey incorporated questions about the information medium used the last time to obtain health information and the frequency of online media used to search for health topics. In addition, the survey asked about the frequency with which the individuals shared health topics through social networks and whether they checked this information before sharing it. As another means of measuring the individual's use and ability to use digital media to obtain health information, we also used the eHealth Literacy Scale [40], an 8-item instrument to measure the individual's digital health literacy, which has been previously validated in Spain [41].
COVID-19 diagnoses, protective measures, and health status	With the intention of evaluating the association between health and positioning around the different COVID-19 issues, respondents were asked whether they had taken the COVID-19 test, whether they had been vaccinated, and what was the degree of compliance with protective measures during the state of alarm in Spain. This last variable was obtained as the mean of compliance with confinement, social distancing, use of masks, hand washing, and diagnostic testing of contacts. In addition, they were also asked about their self-perceived health and whether they had any chronic disease.
Social and economic indicators	Demographic, social, and economic variables were also incorporated in the questionnaire. Specifically, sex, age, income, size of municipality, educational level, employment status, and nationality were collected. In addition, given the relationship shown with cultural and ideological aspects of the individual and the predisposition to misinformation, we also included political ideology (on a scale of 0-10, where 0 meant extreme left ideology and 10 meant extreme right ideology). Ideology was categorized so that a value of 0 to 1 represented far left wing, a value of 2 to 3 represented left wing, a value of 4 to 6 represented center, a value of 7 to 8 represented right wing, and a value of 9 to 10 represented far right wing. An extra category, nonresponse, for those who preferred not to reveal their ideology was also included. Individual religiosity was also assessed (where 0 meant not religious at all and 10 meant very religious) along with trust in institutions (the Spanish government, political parties, World Health Organization, health personnel, and the Spanish National Health System). Finally, as an analysis of the use of new technologies, we added a question about the knowledge and use of artificial intelligence models, which may pose a risk for increasing misinformation [42], and attitudes toward cryptocurrencies, a relationship that has been found to be associated with conspiracy beliefs [43].

Data Analyses

First, an exploration of the characteristics of the sample through descriptive statistics was carried out. After that, a dimensionality analysis was conducted on the COVID-19 Misinformation Scale, through an exploratory factor analysis (EFA). To determine the number of initial dimensions of the items, the criteria of the number of eigenvalues >1 and the conceptual meaning of the factors were considered. We used the weighted least squares mean and variance adjusted estimator as a factor extraction method [44] because it is the most suitable method for Likert scale items and the geomin rotation [45] as an oblique rotation method. This rotation method presents the advantage of balancing simplicity and realism when interpreting factor structures. Unlike orthogonal rotations, geomin allows correlations between factors and minimizes small factor loadings, making it particularly suitable for exploring complex latent structures where variables may load on multiple factors, thereby enhancing the interpretability and precision of the results.

Once the factors were derived from the EFA, we aimed to categorize individuals into groups based on their scores on the dimensions, using the k-means clustering technique. In an attempt to offer an exhaustive classification but at the same time a simple and operational one, participants were initially classified into three categories: (1) convinced-—those who believed or followed the majority opinion according to existing research evidence on COVID-19; (2) hesitant—individuals who expressed doubts, characterized by delays in accepting or rejecting COVID-19 information despite its availability; and (3) skeptical—those who tended to believe or follow minority opinion on COVID-19 issues that are erroneous, false, or misleading and commonly based on anecdotal evidence. This decision was made to simplify the results, as the silhouette method indicated that the 3-cluster solution provided a better classification than other groupings. Accordingly, these 3 categories were used to obtain the different individual profiles by testing their relationship with the variables associated with health information resources and use, COVID-19 diagnoses, health status, sociodemographic variables, ideology, and knowledge of technologies through a multinomial logistic regression model. The group of those individuals who were considered convinced was considered as the reference category, and independent variables with n categories were recategorized into n–1 dichotomous variables.

All the analyses were conducted using R (version 4.1.2; R Foundation for Statistical Computing) and RStudio (Posit PBC). To perform the EFA analyses, the *Lavaan* package [46] was

XSL•FO
RenderX

used, which incorporates the most up-to-date estimators for categorical variables.

Ethical Considerations

This study was approved by the Ethics Committee on Non-Biomedical Experimentation and Genetically Modified Organisms (CEENB-GMOs) of the University of Cadiz (005_2024). All data collected through the telephone survey were fully anonymized prior to analysis. No personally identifiable information was recorded or stored, ensuring complete confidentiality of participants and no financial or material compensation was provided to participants. Participation in the study was voluntary, and verbal informed consent was obtained at the beginning of the interview process.

Results

Table 2 shows the characteristics of the population of the representative sample of 2200 people that participated in this study. As can be seen, the sample was clearly balanced in accordance with the sex and age of the interviewees. In terms of the variables associated with COVID-19, a substantial percentage of vaccination (2088/2200, 94.91%) and a high follow-up of the measures during the pandemic (mean 4.47 out of 5, SD 0.69) were found. Almost 39.05% (859/2200) of the population had been diagnosed with COVID-19 at the time of the survey.

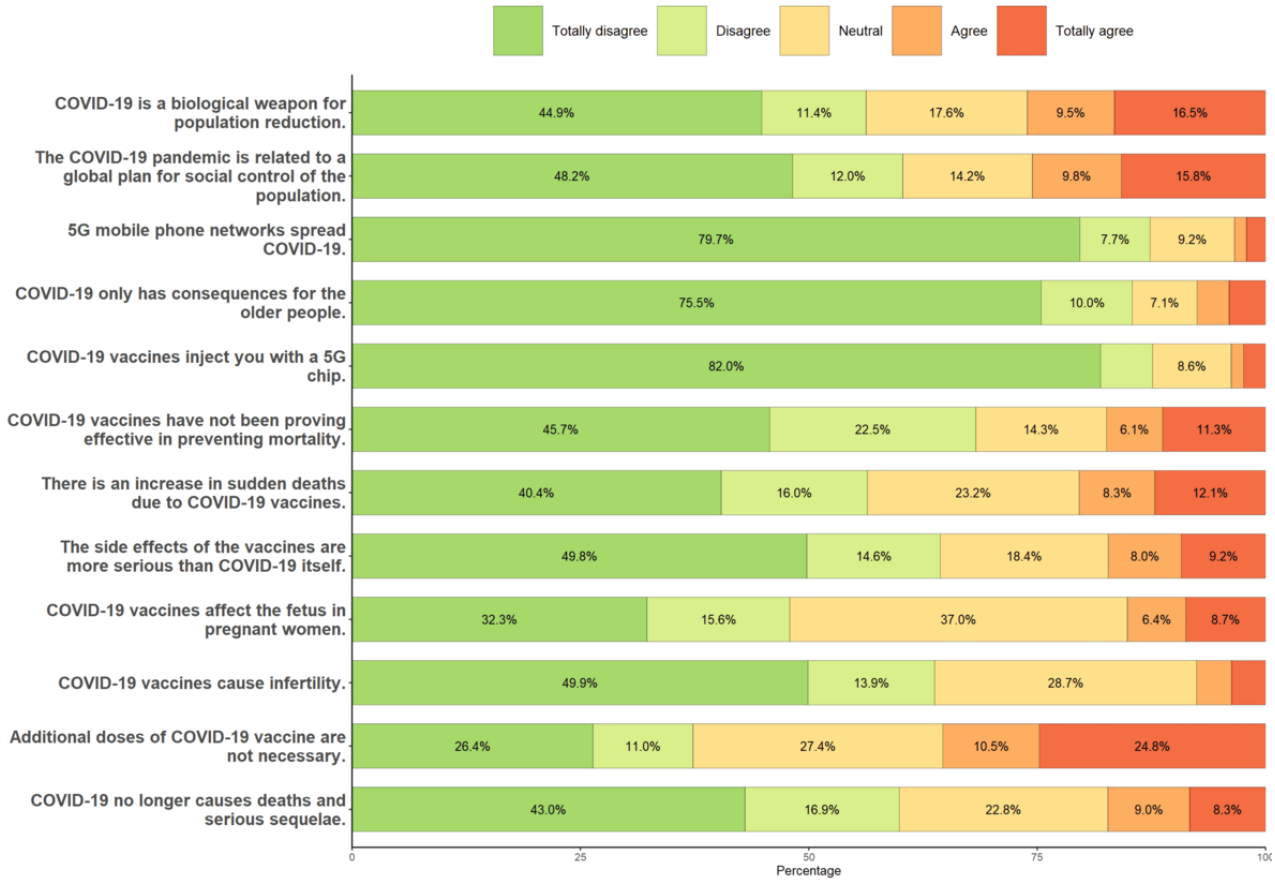
[a]N/A: not available due to missing data.



[b]AI: artificial intelligence.

Regarding the variables that could be associated with beliefs, attitudes, or knowledge that led to misinformation, there was a high level of distrust in political parties (1613/2200, 73.32%) and in the Spanish government (1077/2200, 48.95%). The general population had a medium level of digital health literacy (3.29 out of 5), with the value being somewhat higher in women. The main source of obtaining information on health was from health care professionals (1332/2200, 61.21%), while online information was obtained from institutional websites (522/2200, 24.63%), Google (375/2200, 17.7%), and Wikipedia (343/2200, 16.19%). Up to 34.23% (698/2200) of the participants stated that they did not check the health information they shared through online media.

Figure 1 shows the results of the COVID-19 Misinformation Scale. The items on the need for new doses of vaccines (777/2200, 35.32% thought there is no need for more) and the conspiracy surrounding COVID-19 (572/2200, 26% thought it was a biological weapon, and 559/2200, 25.41% thought it was related to a population control plan) stood out. They also negatively highlighted the sudden increase in deaths (862/2200, 39.18% strongly agreed, agreed or neutral). By contrast, the items concerning the beliefs about the relationship between COVID-19 and 5G mobile network were the ones that caused the least doubts in people, together with the statement that this disease only affected older people.

XSL•FO
RenderX

Figure 1. Summary of the COVID-19 misinformation statements.

To summarize the information and investigate the structure of these 12 items, a factor analysis was performed. The Kaiser-Meyer-Olkin statistic and Bartlett test showed that the data were suitable for factor analysis (Kaiser-Meyer-Olkin=0.91; *P*<.001). The results are presented in Table 3. As there were 3 eigenvalues >1 in the polychoric correlation matrix, factorial solutions from 2 to 5 dimensions were reviewed; it was found that the one that made the most conceptual sense was the one with 4 factors, with an explained variance of 64.8%. After performing the geomin rotation, all 12 items presented factor loadings >0.4 without cross loadings between factors, and only 1 item (ie, COVID-19 no longer caused sequelae) had a communality <0.3, although it remained in the model because it had a factor loading >0.4.

[a]Italic indicate the highest factor loading for each item.

[b]Not applicable.

Factor 1 grouped the 2 items associated with the COVID-19 conspiracy ideas of the existence of a global plan to reduce or control the population. The second factor grouped general health beliefs, such as the link between COVID-19 and 5G technologies, and the supposed impact of the new disease on older groups and mortality. The third factor grouped the claims associated with vaccines, while the fourth factor grouped the 2 items on the fertility consequences of the pandemic. A k-means cluster analysis was used to identify distinct groups of individuals based on their beliefs about the 4 factors extracted from the EFA. The aim of this analysis was to detect 3 distinct subgroups within the population, those who were informed of certain information about COVID-19 and those who had doubts and were skeptics (people who tended to agree with certain COVID-19 misinformation topics). The mean punctuation of the factors by groups can be seen in Table 4.

Table 4. Distribution of 3 clusters of individuals (k-means clustering; N=2200).

Social profiles	Factor 1: global plan, mean (SD)	Factor 2: health beliefs, mean (SD)	Factor 3: vaccine hesitancy, mean (SD)	Factor 4: fertility impact, mean (SD)	Individuals, n (%)
Convinced	1.13 (0.33)	1.30 (0.39)	1.71 (0.61)	1.61 (0.72)	1078 (49)
Hesitant	2.93 (0.88)	1.65 (0.57)	2.57 (0.75)	2.33 (0.85)	666 (30.27)
Skeptical	4.47 (0.70)	2.33 (0.91)	3.77 (0.83)	3.43 (0.96)	456 (20.73)

The largest group was composed of what we have called convinced individuals, accounting for almost half of the sample (1078/2200, 49%), while 30.27% (666/2200) of the individuals were classified as hesitant (ie, individuals reluctant to believe COVID-19–related information), and 20.73% (456/2200) of the individuals were in the skeptical group. Within the latter group, the score on the factor about conspiracies stood out, with a mean close to the maximum of 5 as well as a score that was also high on the statements about vaccines. The 2 factors, vaccines and conspiracies, were the main factors to classify the people who believed misinformation about COVID-19 (the factor with the biggest mean score in the hesitant and skeptical individuals).

The final step involved determining the variables associated with membership in these groups through a multinomial regression analysis, the results of which are presented in Table 5. With these variables, the regression model was able to detect

XSL•FO
RenderX

64.82% (1426/2200) of the people in their corresponding group. Among the socioeconomic variables, sex stood out, with a higher probability of women belonging to the skeptical group (OR 1.699; 95% CI (1.187-2.433); *P*=.004). In addition, both the education and income level variables acted in a similar way—the higher the level of education and income, the lower the probability of belonging to the skeptical group, adding also, in the case of educational level, a lower probability of belonging to the hesitant group. The size of the municipality also influenced the results with people in intermediate-sized municipalities (50,000-100,000 inhabitants) having a lower probability of belonging to the group with more skeptics (ie, the skeptical group).

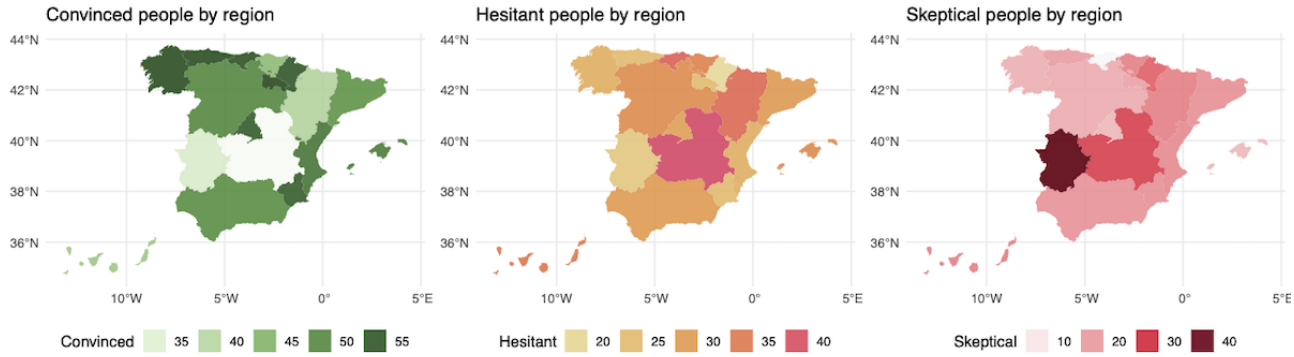
Regarding the time of information and the search for health resources, it was observed that those who sought information through health personnel and written media (ie, books and newspapers) were less likely to belong to the skeptical group than those who searched on the internet. Similarly, among those who searched on the internet, those who searched on institutional websites were more likely to belong to the convinced group. Sharing on social media more frequently was associated with a greater probability of belonging to the skeptical group; however, there was no relationship with contrasting the

XSL•FO
RenderX



information before sharing it. The degree of digital health literacy of the individual, as measured by the eHealth Literacy Scale, also showed no relationship with the group to which they belonged.

With respect to certain individual thoughts, we found some relationships of interest. Political ideology showed how individuals on the far right and even those who did not want to declare their ideology (ie, possibly those showing political disaffection) were more likely to belong to the skeptical and hesitant groups with respect to individuals who held a moderate political position (whether they positioned themselves on the left or on the right on the ideological scale). In turn, distrust in certain institutions was shown to be a factor related to skepticism (specifically, distrust in political parties, the WHO, and the Spanish National Health System). The same relationship was shown for religiosity—the higher the degree of religiosity, the greater the probability of belonging to the skeptical group.

Reviewing the variables associated with the COVID-19 pandemic and health, not having been vaccinated for COVID-19 and lower compliance with protective measures during the pandemic were associated with individuals belonging to the skeptical group. By contrast, diagnosis of COVID-19, having chronic conditions, and self-perceived health did not present statistically significant relationships.

Finally, to obtain a contextualized representation of the different groups that we had characterized, we proceeded to study their regional distribution in the country as a whole. Figure 2 shows the maps for the 3 groups: convinced, hesitant, and skeptical. The spatial distribution of these groups on the map of Spain showed that the skeptical groups were found to a greater extent in the so-called empty Spain (particularly in regions such as Extremadura and Castilla-La Mancha), that is, those rural areas of the country characterized by a low population density due to the exodus of young people to the main urban areas. This is a trend that to some extent was also observed with the individuals in the hesitant group, who were also more prevalent among regions of lower population density.

Figure 2. Geographic distribution of convinced, hesitant, and skeptical groups.

Discussion

Principal Findings

This study sheds light on how misinformation related to COVID-19 spread through different social strata of the Spanish population. In line with previous research conducted in other countries, this study reinforces the assumption that social factors, such as political ideology, socioeconomic status, and trust in institutions, play a significant role in determining susceptibility to misinformation [47,48]. However, unlike other studies, our research provides a geographic identification and a comprehensive characterization of the social profiles that are at risk of using erroneous, false, or misleading information as well as a detailed description of the pandemic-related topics that, even today, continue to generate social polarization among the population. Specifically, we have detected that the social profiles most susceptible to misinformation in Spain—in addition to belonging to extreme right-wing ideologies, presenting a low level of socioeconomic status and having a greater distrust of institutions and public health systems—tend to a greater extent to be women without a defined political orientation (possibly due to political disaffection), who use lower-quality information sources (such as social media) and generally unofficial ones, even though they easily share the health information they find through these unofficial media. Likewise, they are groups that reject the COVID-19 vaccines and have shown a lower follow-up of the protective measures decreed by the health authorities during the pandemic.

Among the most relevant topics on misinformation related to COVID-19, it can be emphasized that the themes of the ineffectiveness of additional vaccine doses, pandemic conspiracy theories, and claims of a sudden rise in mortality rates were the topics that elicited the most doubt or agreement within the Spanish population. More than 20% of respondents believed that COVID-19 vaccines lead to a sudden rise in mortality, a perception that likely undermines public motivation to receive further doses. Although Spain is a country with high vaccination rates, these data show that it is necessary to improve the quality of the information provided to the population about the beneficial effects of vaccination and, in particular, existing evidence related to COVID-19 vaccination data. By contrast, the items on the relationship between COVID-19 and 5G mobile

XSL•FO
RenderX

phone network are the ones that cause the least doubts in people, as in other studies that have shown that the narrative linking the onset of the pandemic to 5G antennas is the content that people were least likely to believe [30]. In any case, it is necessary to take into account that a small percentage of the population believes this type of hoax.

Cluster analysis allowed us to obtain 3 groups of individuals based on their beliefs toward COVID-19 content. Being a study with a representative sample of the Spanish population, it is relevant to mention that 20.73% (456/2200) of the respondents have been classified in the group of skeptical individuals or the cluster that tends to believe erroneous, false, or misleading information (ie, commonly based on anecdotal evidence more than on real facts and existing scientific evidence). In addition, 30.27% (666/2200) of the participants could be classified as hesitant individuals who express doubts about the current evidence regarding COVID-19. This percentage is notably high for a general population study and reflects a significant level of uncertainty around COVID-19 among the Spanish population. According to this finding, a work conducted by the Spanish Foundation for Science and Technology in 2022 on scientific misinformation in Spain found that more than a quarter of the population living there received false or misleading information about science on a weekly basis [49]. These data, combined with our findings, underscore the magnitude of the problem of misinformation and the risk of having a high percentage of hesitant population (ie, those who are more susceptible to behavioral changes based on the influence of external information sources independent of their quality). Furthermore, it becomes clear that misinformation not only affects all social strata but also has a clear impact on public health through health behaviors (eg, the rejection of vaccines and protective measures against COVID-19).

The factors related to COVID-19 that best differentiated the groups were those associated with conspiracy theories and COVID-19 vaccination. This finding aligns with previous research [50], demonstrating a strong link between belief in misinformation and a conspiratorial worldview, where individuals suspect that both government and institutions are the root of societal problems. Besides, the strength of content related to antivaccine movements stands out in our study, which is positioned as one of the most relevant misinformation topics in other studies [23], and it is one of the most relevant topics among COVID-19 skeptics who embrace misinformation and conspiracy theories. From these findings, it is evident that the hoaxes associated with vaccines are one of the most difficult narratives for institutions to alleviate [35].

In addition to the analyzed data on the prevalence of misinformation in Spain and its social determinants, our study has identified an interesting geographic distribution of misinformed groups that curiously coincides with the rural areas belonging to the so-called empty Spain, regions that, despite being led by both right-wing and left-wing political parties (eg, Castilla-La Mancha and Extremadura, respectively), have the common characteristic of having a low density of population compared with other country areas. Thus, the higher prevalence of the skeptical group in these areas could be due to the high degree of rurality that could imply, on average, both a lower socioeconomic status of the population (ie, lower education, income, and occupational status) and a certain degree of political disillusionment with the country's main political parties in view of the scarcity of policies to reverse the demographic situation of these areas. As discussed by Southwell et al [51], limited community infrastructure and reduced social cohesion in geographically isolated areas can constrain the diffusion of health information and facilitate the persistence of misinformation, particularly in rural areas such as the empty Spain. This factor may partially explain the observed geographic distribution.

Our findings indicate that individuals with lower socioeconomic status were more likely to be linked to the skeptical group. This aligns with international studies showing that this factor is a clear predictor of health misinformation [52]. However, women were also found to be prone to skepticism, a finding that warrants further investigation to understand gender-specific factors driving COVID-19 misinformation vulnerability, as other studies on gendered scientific misinformation in Spain show that women differentiate misinformative content better than men [49], contrary to the data from our study. It is likely that the role played by misinformation narratives about COVID-19 vaccines and problems with fertility or births is a factor influencing these gender differences [53].

Interestingly, this study highlights the association between institutional trust and misinformed beliefs and conspiracy theories about COVID-19. In the Spanish context, the strong distrust in political parties, the government, and institutions further exacerbated skepticism [38]. While political polarization has been shown to influence misinformation in other countries, our study found that mistrust in health-related institutions, such as the Spanish National Health System and the WHO, was a key determinant of scientifically unsupported opinions linked to skeptical groups in Spain [54]. Therefore, as highlighted in previous studies, this finding underscores the critical role of misinformation in shaping institutional and governmental trust [55], reinforcing the necessity for health institutions to re-establish credibility through transparent communication strategies and consistent messaging. Moreover, as Agley and Xiao [30] point out, it is necessary to keep in mind that believing in false information or conspiracy theories does not necessarily imply that a person cannot simultaneously believe in the official scientific versions. Consequently, simply repeating accepted scientific explanations will not necessarily stop people from believing false information (eg, people who have trust in vaccines but reject COVID-19 vaccines) or even, in practice, combining scientific and anecdotal evidence to make health decisions. Thus, new strategies are needed to strengthen scientific literacy and confidence in science through research transparency and outreach by those individuals working in the scientific field, along with specific knowledge about new technologies that, like the new RNA vaccines, raise more doubts among the population in our countries.

Contrary to some findings that suggest a strong protective role for digital health literacy against misinformation, this study did not find a significant relationship between digital literacy (as measured by the eHealth Literacy Scale) and susceptibility to health misinformation [56]. Instead, the quality of the

XSL•FO
RenderX

information sources emerged as a more decisive factor. Individuals who relied on health professionals, institutional websites, and official media (eg, newspapers) were less likely to be misinformed and subsequently skeptical about COVID-19–related topics. These findings suggest that public health interventions should promote reliable and well-identifiable information sources over simply enhancing digital literacy skills. In addition, consistent with global studies, our analysis also found that individuals in the skeptical group were more likely to share health-related information on social media frequently [57]. This behavior can be linked to the psychological need for validation within communities, which also drives the spread of misinformation and the formation of echo chambers in which possibly many of these beliefs are fed back [58]. Thus, public health campaigns should not only aim at promoting critical thinking but also address the emotional and psychosocial aspects of information and misinformation sharing.

A distinctive aspect of this study was the nuanced role of political ideology in misinformation beliefs. Thus, although like other international studies we identified the strong association between ideologically extreme positions and greater susceptibility to misinformation [16], our results suggest that those who did not disclose their political stance were more likely to belong to the skeptical or hesitant groups, a finding that could be linked to the political disaffection that currently exists in Spain among voters on both sides of the political spectrum. This finding, combined with data on the geographic distribution of the hesitant and skeptical groups around the empty Spain, underscores the importance of considering both political disaffection and extremism as key drivers of health misinformation and social polarization in health behaviors in the Spanish context [59].

Finally, in interpreting our findings, it is essential to recognize that not all misinformation operates with equal epistemic weight or public impact. As emphasized in the report by National Academies [27], some claims, such as those concerning vaccine safety, are clearly at odds with established scientific evidence, whereas others may stem from misunderstandings of evolving science or reflect contested interpretations. Therefore, this complexity in apprehending the inherently fluid nature of misinformation highlights the need for nuanced classification and targeted interventions, particularly in public health communication strategies that aim to distinguish deliberate disinformation from more benign forms of confusion or outdated beliefs.

Limitations

Despite these interesting findings, our work is not without limitations. Given the observational nature of this study, it is not possible to draw causal inferences from the results. Similarly, the cross-sectional design of this study does not allow us to determine the extent to which the responses remain influenced by the social changes brought about by the measures implemented during the pandemic. In addition, the clustering techniques used are not free from potential errors in classifying individuals into groups. Nevertheless, in this study, we have opted to combine the best model fit with criteria of simplicity, interpretability, parsimony, and applicability to other international contexts. In any case, it is also important to highlight the strengths of our work. First, we have identified misinformation topics related to COVID-19 that continue to generate doubts and polarization among the Spanish population. Second, to the best of our knowledge, our study is the first to measure the prevalence of convinced, hesitant, and skeptical groups around COVID-19–related topics in Spain using a nationally representative survey. Third, we have provided a comprehensive characterization of the different social profiles that are susceptible to misinformation in Spain and described their geographic distribution. In summary, our study offers crucial insights into the scope of measures that should be adopted and, particularly, the social determinants that could be targeted to combat misinformation.

Conclusions

This study provides a comprehensive overview of COVID-19–related misinformation in Spain, offering valuable insights into the social, economic, and ideological factors that influence susceptibility to false or misleading information. By identifying and profiling the convinced, hesitant, and skeptical groups, we have demonstrated the significant polarization surrounding health-related issues, such as vaccine hesitancy about the new vaccines and conspiracy theories. These findings emphasize the importance of targeted interventions to improve public understanding of complex health information to combat the global threat of misinformation. Our findings highlight the critical role of institutional trust in shaping public attitudes and health behaviors, underscoring the need for health and governmental institutions to rebuild credibility through transparent communication and consistent messaging. In addition, the influence of socioeconomic status, political ideology, and information sources on misinformation susceptibility suggests that addressing these structural determinants is essential for the design of effective public health strategies.

From a broader perspective, this study contributes to the global research stream on the impact of misinformation on health behaviors, particularly in the context of future pandemics or health crises. Future research should explore longitudinal approaches to examine how misinformation beliefs evolve over time and assess the effectiveness of interventions designed to reduce the spread of false information. Furthermore, exploring the role of digital literacy, alongside strategies to promote reliable, evidence-based information sources, is crucial to addressing the challenges of emerging information and misinformation ecosystems, especially as we await the full impact of new artificial intelligence technologies. Our findings highlight the necessity of a multifaceted approach that integrates education, health policy development, media platforms, and community engagement to effectively counter the persistent menace of health misinformation.

Abstract

Background: The outbreak of SARS-CoV-2 in 2019 was accompanied by a rise in the popularity of conspiracy theories. These theories often undermined vaccination efforts. There is evidence that the spread of misinformation about COVID-19 is associated with online social media use. Online social media enables network effects that influence the dissemination of information. It is important to distinguish between the effects of using social media and the network effects that occur within the platform.

Objective: This study aims to investigate the association between the modularity of online social networks and the spread of, as well as attitudes toward, information and misinformation about COVID-19.

Methods: This study used data from the social network structure of the online social media platform Vkontakte (VK) to construct an adjusted modularity index (fragmentation index) for 166 Russian towns. VK is a widely used Russian social media platform. The study combined town-level network indices with data from the poll "Research on COVID-19 in Russia's Regions" (RoCIRR), which included responses from 23,000 individuals. The study measured respondents' knowledge of both fake and true statements about COVID-19, as well as their attitudes toward these statements.

Results: A positive association was observed between town-level fragmentation and individuals' knowledge of fake statements, and a negative association with knowledge of true statements. There is a strong negative association between fragmentation and the average attitude toward true statements (P<.001), while the association with attitudes toward fake statements is positive but statistically insignificant (P=.55). Additionally, a strong association was found between network fragmentation and ideological differences in attitudes toward true versus fake statements.

Conclusions: While social media use plays an important role in the diffusion of health-related information, the structure of social networks can amplify these effects. Social network modularity plays a key role in the spread of information, with differing impacts on true and fake statements. These differences in information dissemination contribute to variations in attitudes toward true and fake statements about COVID-19. Ultimately, fragmentation was associated with individual-level polarization on medical topics. Future research should further explore the interaction between social media use and underlying network effects.

Introduction

Background

The COVID-19 pandemic challenged many societies. Governments had to reduce mortality risks while minimizing economic shocks. One of the most efficient ways to mitigate such impacts is vaccination. There is considerable variation in people's behavior regarding vaccination [1]. Evidence suggests that one of the factors associated with increased vaccine hesitancy was the use of social networking and belief in COVID-19 fake news and conspiracy theories [2-4].

Pivetti et al [5] proposed a mechanism that links social media usage, COVID-19 fake news, and vaccination hesitancy. First, online social media users are more likely to encounter misinformation about COVID-19 compared with traditional media users [6]. Second, exposure to fake news increases the likelihood that some users will believe in conspiracy theories [3]. Belief in conspiracy theories, in turn, raises the perceived risk of vaccination while lowering the perceived risk of the disease [7]. Finally, these altered risk perceptions reduce the likelihood of vaccination and negatively impact other preventive behaviors [8,9].

However, a causal relationship between online social media use and belief in conspiracy theories has not yet been established. Moreover, there is evidence that the unavailability of social media positively influences the popularity of searches for COVID-19 fake news [10]. Finally, social media can also promote proscience or provaccine messages that reduce vaccination hesitancy [11,12]. In other words, what matters is the content observed on social media, not social media use itself.

It is important to study the Russian case of COVID-19 pandemic attitudes for several reasons. Russia exhibited relatively high levels of vaccine hesitancy [1], which may have contributed to one of the highest excess mortality rates in the world [13,14]. Additionally, the availability of data and variation at both the individual and town levels offer valuable tools for examining the issue.

Theories concerning the consumption of information on online social media generate mixed hypotheses. On the one hand, prior beliefs may be reinforced by filter bubbles created by social networking site algorithms that tailor users' feeds to match their interests [15]. Echo chambers further enable individuals to interact primarily with others who share similar views [16]. On the other hand, individuals may also encounter differing perspectives online [17], which can increase the diversity of their views.

The spread of misinformation about COVID-19 is supported by echo chamber theory and evidence that homogeneous groups are more likely to disseminate fake news [18-20]. However, when information escapes an echo chamber, only a minority of outsiders accept it [18]. According to the opinion dynamics model [21], individuals are likely to change their beliefs only when the ideological gap with the person they interact with is small. Similarly, there are homogeneous groups that disseminate scientific information as well [16]. Previous review studies have shown that it is primarily human users, rather than bot accounts, who spread fake news to most users [22], underscoring the importance of studying the networks of ordinary users.

This paper provides evidence on the indirect effects of online social media on misinformation diffusion and the formation of personal beliefs. The study findings indicate that it is not only the platform that matters but also the structure of citizens' online interpersonal networks. In this study, data on the characteristics of online social media networks on Vkontakte (VK) were combined with polling data from users in the corresponding towns. It was shown that town-level fragmentation of these networks is associated with the spread of misinformation about COVID-19 and the share of fake statements encountered by respondents. The results remain robust after controlling for individual characteristics, including the use of online and traditional media, fear of COVID-19, and household experience with the disease. This study contributes to the growing literature on the spread of health misinformation on social media [23].

The presented approach differs from studies that rely solely on online social media data. Numerous studies have examined the spread of specific conspiracy theories within online environments [23]. However, a key question remains: how does the social environment—measured through a network index—affect an individual's likelihood of encountering true or false statements about COVID-19? Finally, how do networks shape opinions about these statements, and what role does online social media play in this process?

Related Work

This section is divided into a brief literature review covering studies on information diffusion in social networks, network modularity, and its outcomes. These areas are explored to understand how information spreads within networks and how modularity influences social outcomes. Following this, the estimation of fragmentation will be discussed and the formulation of hypotheses will be presented based on the literature review and methodological approach.

Information Spread in the Network

Information diffusion refers to the process of spreading information among agents or communities within a network [24]. The efficiency of this diffusion is influenced by the network's structure and the characteristics of its nodes and links. The concept of the "strength of ties" introduces the role of interpersonal trust between individuals in a network [25]. Strong ties exist between nodes that share many neighbors, while weak ties connect nodes with fewer common neighbors. In social interactions, strong ties typically form between individuals who know each other well. While strong ties are more effective for persuading people within the network, weak ties can facilitate broader and more efficient information spread [26]. Homophily—the tendency of similar nodes to group together based on shared traits—also enhances the speed of information diffusion within these clusters [27]. At the structural level, the concept of communities is central; communities are groups of nodes clustered based on their connectivity [28]. Modularity, which measures the strength of the division of a network into communities, plays a significant role in shaping how information diffuses [29-31]. The foundational theoretical framework for

XSL•FO
RenderX

studying information diffusion is the Epidemic Spread Model [32].

All of these theories are interdependent; for example, higher homophily is expected among nodes within the same community. In other words, individuals with more ties to each other are likely to share common characteristics. In this study, no personal information about the nodes in the network was used, which limits the range of analytical tools available. Instead, the modularity index was used to measure potential polarization within a town [29].

Network's Modularity and Its Outcomes

Network modularity influences the speed of information flow within a network [30]. In animal networks, modularity has been shown to affect the efficiency of information transmission in a nonlinear manner [31]. Similarly, in the context of COVID-19, the structure of the network influences disease spread even when the total number of links remains constant [33]. Strategies that incorporate knowledge of community structure significantly improve the efficiency of containment efforts at the town level [33-35].

Previous studies have examined the fragmentation of online social networks and the spread of misinformation within them. For a review of the spread of fake news and belief change, see [36]. These studies have shown that individuals within the same community are more likely to influence each other's opinions than outsiders. A concept particularly relevant to this study is that of epistemic echo chambers [37], which arise when individuals rely primarily on their social networks for information, and when those networks are fragmented—thereby limiting exposure to diverse viewpoints.

Several studies have examined the relationship between network modularity and economic or social outcomes. In this context, modularity is used as a tool to capture social capital. For instance, the modularity of networks at the municipal level has been shown to predict economic development [38], while at the town level, it has been linked to levels of corruption [39]. More broadly, network modularity serves as one indicator for predicting societal polarization at the network level [29].

Most studies have focused on how misinformation about COVID-19 spreads online, how social media use influences vaccination intentions [3], or knowledge of specific conspiracy theories [18]. For a review of studies on this topic, see [3,40].

What distinguishes this study from previous work is its focus on the indirect effects of network modularity on the town-level spread of information and misinformation. Specifically, the author posits that the likelihood of epistemic echo chambers emerging in a town is correlated with the fragmentation of its network. The study estimates the association between the fragmentation of VK's social media network at the town level and the likelihood of individuals encountering fake news and related opinions, while controlling for individual characteristics. The study findings suggest that online social media polarization and fragmentation can have broader consequences, extending beyond individual opinion formation to affect information dynamics at the community level.

Methods

Fragmentation Index as Network's Modularity Measure

As shown previously, network structure plays a key role in the transmission of information. At the macro level, the focus shifts to communities, where understanding how members are interconnected becomes essential. To capture this, a modularity index was used as a measure of network interconnectedness. In this study, an improved version of the modularity index was applied to better account for differences in network size.

The *fragmentation index* indicates the extent to which nodes tend to cluster together and remain separate from others. The Louvain algorithm [41] divides a network into relatively segregated groups (communities). It should be noted that the problem of community detection is NP-hard; therefore, the algorithm provides a heuristic solution. The fragmentation index estimates the likelihood that edges occur within small groups rather than between them.

Equation 1 represents the modularity index of the network that captures the ratio of ties with and between community members, where L is the number of edges in the network, L_k is the number of edges adjacent to members of community k, L_k^w is the number of edges within community k, and $Q(S)$ is the modularity of the network.

Equation 2 shows the adjustment for modularity calculated on the alternative network if all ties were within community members, where $Q_{max}(S)$ is the theoretical maximum if all edges were within the communities.

Equation 3 represents the fragmentation index:

$$F_s=[Q(S)]/[Q_{max}(S)] \quad (3)$$

In other words, the fragmentation index is a modularity measure adjusted for network size, allowing for meaningful comparison of network structures across different sizes. This methodology follows previous research in the field [39,42].

The modularity index has been shown to influence the spread of information [30,31,43]. Moreover, it has been established that a network's modular structure, as measured by the modularity index, affects the spread of diseases [33]. Both processes are modeled using the same basic theoretical framework [32].

Hypothesis Formulation

Higher fragmentation indicates that there are more connections within communities than between them. In such networks, information is more likely to circulate within a community rather than spread across communities. If we assume that community members share certain characteristics that make them more similar to one another than to outsiders, they are more likely to agree with the information they encounter and

XSL•FO
RenderX

to disseminate it further [18]. This, in turn, increases the likelihood of repeated exposure to the same information.

Building on the theory of the strength of weak ties [25], the diversity-bandwidth trade-off—comparing the properties of weak ties with strong ties—can also be applied at the community level [26]. Existing literature shows that both conspiracy theories and scientific news tend to spread within closed, homogeneous groups [16,44]. In more fragmented networks, such groups are more likely to exist, as higher homogeneity increases the probability that individuals belong to the same community. While both weak and strong ties can facilitate the spread of new information, the effectiveness depends on the type of information and the surrounding environment [26]. In the context of online news dissemination, the prevalence of strong ties does not necessarily offer an advantage—unless trusted users (those with higher bandwidth) are more likely to believe in and share accurate information.

- Hypothesis 1(a): Fragmentation is negatively associated with the relative number of true statements about COVID-19 encountered.

Lower fragmentation implies the presence of more weak ties, which can facilitate the spread of accurate information in the context of news dissemination. In less fragmented networks, individuals who believe in fake news are more likely to be connected to others with differing views, increasing the chances of exposure to corrective information.

In other words, while less fragmented networks tend to exhibit a greater diversity of views, the likelihood of encountering fake information online is lower. This is because individuals who believe in fake news are less likely to share it in such environments, as the audience response to these posts tends to be weaker. This behavior can be explained by the concept of strategic self-presentation [45,46]. Users are more likely to share content that portrays them favorably and garners positive feedback from others. In diverse networks, posts expressing extreme views are likely to be received less favorably due to greater ideological distance between the poster and the audience. As a result, more neutral content is amplified, as it attracts broader approval. While this mechanism is particularly pronounced on online platforms due to algorithmic reinforcement [36], it also holds relevance in offline social interactions.

- Hypothesis 1(b): Fragmentation is positively associated with the relative number of fake statements about COVID-19 encountered.

In towns with more fragmented networks, individuals are more likely to be divided into numerous closed communities. This structure fosters epistemic echo chambers, where exposure to diverse viewpoints is limited [37]. Within such communities, the spread of fake news and conspiracy theories is more likely to occur, increasing the chances that individuals connected to or adjacent to these communities will encounter misinformation.

- Hypothesis 2(a): Fragmentation is negatively associated with belief in true statements about COVID-19.

Groups within fragmented networks are more likely to share similar views and exert strong influence on one another's opinions [36]. That is, individuals within the same community tend to hold similar beliefs. However, different communities within the same network may hold opposing views, contributing to overall polarization. Within individual communities, lower diversity of opinion, fewer weak ties, and reduced efficiency of information flow may limit exposure to accurate information. As a result, individuals in more fragmented networks may be less informed and less likely to believe true statements.

- Hypothesis 2(b): Fragmentation is positively associated with belief in fake statements about COVID-19.

In more fragmented networks, the spread of fake statements is more likely, as the existence of closed communities where misinformation is accepted and reinforced becomes more probable. Individuals within or adjacent to these communities are more likely to encounter and believe such statements, which are then further propagated. However, the overall effect may be limited. When fake news circulates beyond these echo chambers, it often encounters resistance or negative reactions. Such exposure can prompt critical evaluation among those outside the community, leading to skepticism and potential revisions in belief [18].

Causality

The methodology used in this study does not permit causal inference between network fragmentation, the likelihood of encountering information, and an individual's belief in that information. However, reviews of prior research offer insights into potential causal mechanisms linking information spread and opinion change [36]. Previous studies indicate that fragmented networks are prone to increasing polarization [47], and the dissemination of polarized content can further intensify opinion divergence [48]. Additionally, exposure to opposing viewpoints may reinforce existing beliefs—a phenomenon known as belief entrenchment [49]—whereas exposure to more neutral information can reduce polarization and shift opinions [21].

Summing up, in fragmented networks, the emergence of closed groups that believe in fake news is more likely due to the formation of epistemic echo chambers. Strong believers within these groups may share misinformation beyond their immediate community. However, such exposure is unlikely to change the views of others—particularly if those individuals already hold conflicting beliefs.

Data

The dataset combines the "Research on COVID-19 in Russia's Regions" (RoCIRR) database on COVID-19 in Russia with social network data collected from the most popular online social network, VK. The RoCIRR dataset includes responses from over 23,000 individuals. Data were collected between November 4 and December 1, 2020, through an online survey of respondents from 61 Russian regions, designed to be representative at the regional level. Detailed information about the poll is provided in Multimedia Appendix 1. Respondent recruitment was conducted by Online Market Intelligence, an online polling company operating in Russia and analogous to

XSL•FO
RenderX

Amazon's Mechanical Turk (MTurk) in the United States. Online Market Intelligence maintains a panel of the adult population in cities with over 100,000 residents. In addition, a subsample of respondents was drawn from smaller towns and rural areas for the RoCIRR database. For more details on the RoCIRR dataset, see [50].

From this dataset, towns with more than 10 respondents were selected, resulting in 168 towns. For these towns, VK users were identified using VK API instruments [51] to construct social networks. Additional data sources included official municipal statistics from Rosstat [52] and the main regional socioeconomic statistics from Rosstat [53], which were used to create town-level controls for wages and population. Municipal statistics were missing for 2 towns due to changes in municipality structure; detailed information about this is provided in Multimedia Appendix 2. All responses marked as "difficult to say" were treated as missing observations and excluded from the survey. The final dataset included 16,587 respondents from 166 towns, with an average of 119.2 respondents per town and 88,700 nodes per network. The dataset covered 60 of the 61 regions included in the original sample.

The final dataset includes both smaller towns with populations under 100,000 and major cities such as Moscow and Saint Petersburg. Most towns in the sample (95/166) have populations below 250,000, though large cities (with populations over 500,000) are also represented. The sample comprises both regional capitals and ordinary towns. A detailed distribution of town populations in the sample is provided in Multimedia Appendix 3.

About VK

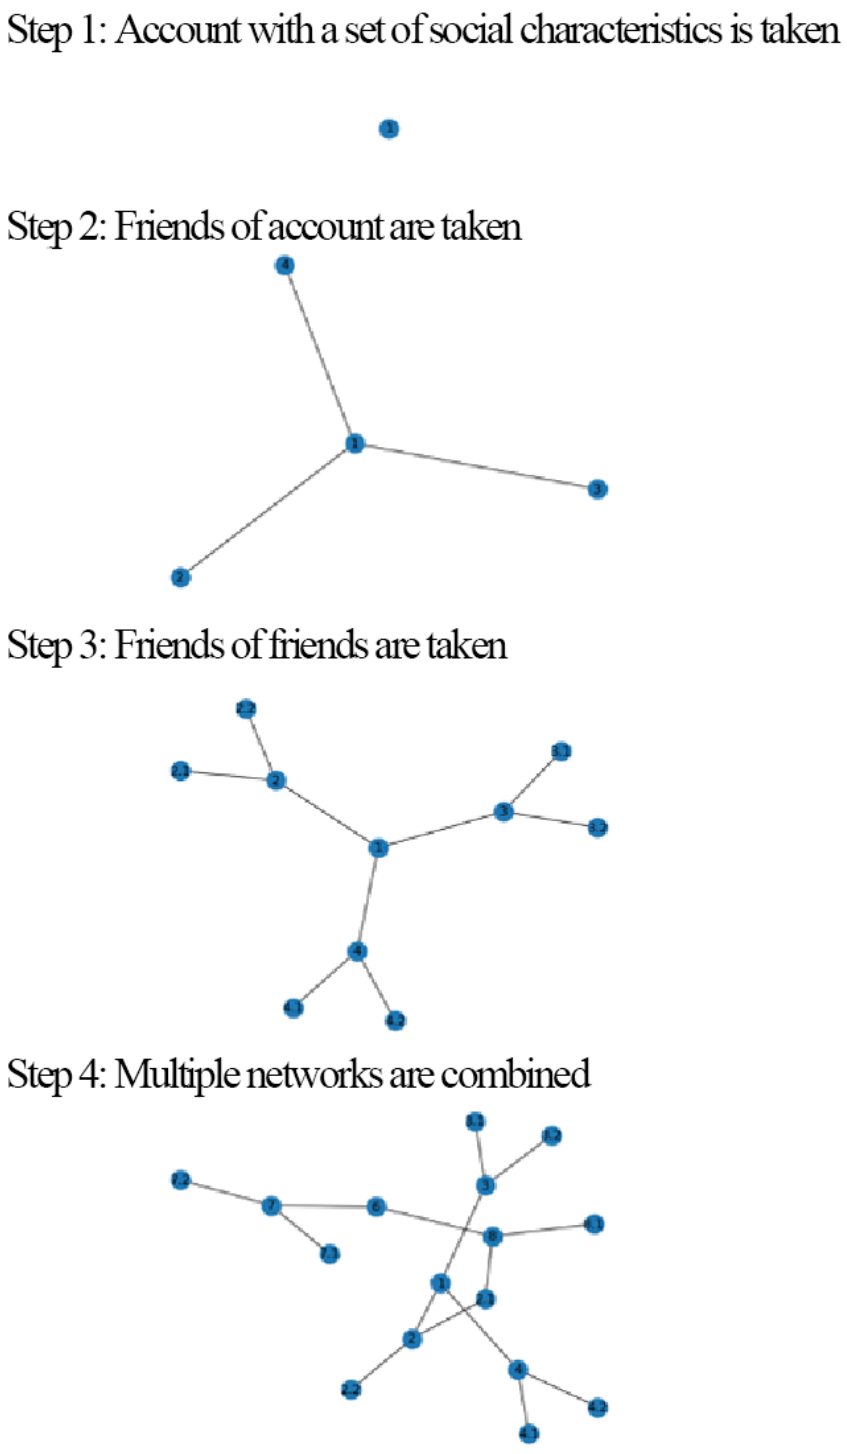
VK is a Russian online social network where users can post public messages, add other users to their "friend" lists, and send private messages. As of November 2023, VK was the fifth most popular website in Russia [54] and the most popular online social network, with over 80 million monthly active users.

Data from VK were collected using the VK API between February 7 and February 25, 2023. It is assumed that networks based on VK data remain relatively stable over time. To support this assumption, 2 samples of the fragmentation index from 2023 and 2024 were used and statistical differences were assessed. It should be noted that community detection algorithms are heuristic, and therefore different runs may result in different node groupings [55]. As a result, observed differences in fragmentation could arise solely from the algorithm's allocation process. Descriptive statistics for the datasets are provided in Multimedia Appendix 4. A paired *t* test (1-tailed) shows no significant differences between the fragmentation indexes from 2023 and 2024 (P=.07). Moreover, it has been shown that the use of retrospective data in online social network analysis is possible, though its effectiveness may be limited by account bans [56].

This section explains the algorithm used to select accounts from VK. For each town, the algorithm attempts to identify accounts based on the following criteria: age group (3 age groups ranging from 18 to 65 years), gender, and number of friends (at least 100 from the same town and no more than 500 in total). In total, accounts are selected from 6 groups—3 age groups, each split by gender. The algorithm was run 3 times, resulting in the selection of up to 18 accounts per town. It should be noted that in larger towns, it is easier to find accounts that meet these criteria due to the larger pool of available accounts. Thus, this method allows for the construction of networks with sizes roughly proportional to the actual population sizes of the towns. The criteria were chosen to simplify calculations, filter out bot accounts at an early stage, and prioritize accounts belonging to individuals likely residing in the towns they list. The threshold of 100 friends is consistent with the mode number of friends observed on platforms such as Facebook and Twitter [57]. Statistical characteristics are presented in Table 1.

Table 1. Characteristics of networks (n=166).

Statistic	Mean (SD)	Range
Fragmentation index	0.449 (0.093)	0.293-0.799
Number of nodes	88,749.800 (81,418.540)	375-541,123
Number of edges	688,859.500 (487,270.800)	2783-2,463,411
Density	0.001 (0.003)	0.00001-0.040
Clustering	0.225 (0.075)	0.030-0.442



Networks for each account are sampled using breadth-first search to a depth of 2. In other words, for each selected account, their friends and the friends of those friends are included—but acquaintances of friends of friends are not sampled. A network representation of the data collection procedure is shown in Figure 1. While breadth-first search introduces a sampling bias toward high-degree nodes, this bias decreases as the proportion of sampled nodes increases [58]. Furthermore, by using multiple accounts to construct each network, randomness is introduced into the sampling process, which helps reduce potential bias [59].

To estimate node and edge coverage, the author proposes calculating proportions relative to the population as the lower limit of coverage, and proportions relative to VK users as the upper limit. The lower limit reflects the representation of a hypothetical social network encompassing all citizens, while the upper limit captures the representation of the actual VK user network. Based on this, the lower bound indicates that 88,750 of the 435,663 (20.37%) 2019 town populations were screened, suggesting that a significant portion of the population is represented in the network. The upper bound of node coverage—adjusted using the share of respondents who reported

XSL•FO
RenderX

using VK—is estimated to be slightly over 30% (88,750/272,766, 32.54%). The lower limit of edge coverage is nearly 3% (688,859/21,783,150, 3.16%), representing the proportion of edges in the sampled graph relative to all social connections of citizens, with the Dunbar number used as the average number of edges [57]. The upper limit of edge coverage reflects the proportion of edges in the sampled network relative to the expected number of edges among VK users from the same town.

Figure 1. Network data collection procedure.

The upper limit of edge coverage was estimated as the product of the proportion of VK users in the total population and the average share of friends from the same town. These calculations yield an upper estimate of edge coverage of nearly 13% (688,859/5,416,402, 12.72%). Details on the estimation of the expected degree are provided in Multimedia Appendix 5. Previous studies have shown that sampling 15% of a graph is sufficient [60]. While the study's sample is smaller, it is

XSL•FO
RenderX

important to note that the effects of sampling bias on community structure are more limited than on other network characteristics. This is because high-degree nodes—which are more likely to appear in a sample than in the full network—are particularly relevant for determining network structure [61]. Therefore, reducing bias by increasing the share of low-degree nodes in a sample may actually harm the preservation of community structure [61]. Furthermore, the relationship between changes in the fragmentation index and the number of accounts sampled was analyzed, as detailed in Multimedia Appendix 5. As expected, an overlap among the combined networks was observed, resulting in diminishing returns in both edge coverage and node coverage as the network size increases. The most significant spikes in edge coverage occur when the first 3 networks are combined. On average, only a modest increase in edge coverage was observed after combining 10 networks. These estimations suggest that some bias may be introduced by the chosen sampling technique, although the study aims to demonstrate that this bias is minimal. Multimedia Appendix 5 presents edge coverage for each account selected in the sampling process. In a subsample of 49 towns, the average edge coverage reaches nearly 16% (543,687/3,406,978, 15.96%) after selecting 14 accounts and increases to over 20% (726,626/3,389,593, 21.44%) with 18 accounts. Note that the number of iterations to create each of the 49 networks varies by city. Thus, as we examine changes in the average edge coverage introduced by each iteration of sampling, the total number of towns in the sample may vary. However, even with all 18 accounts, some towns still show edge coverage below 10% (637,297/6,600,559, 9.66%). Findings from this study indicate that 15 of the 22 (68%) towns in the subsample achieve edge coverage above 24% (779,875/3,136,689, 24.86%) using this method. This suggests that some bias may result from the network sampling approach. To address this, a robustness check was conducted, restricting the analysis to towns with average edge coverage above 15% (739,677/4,917,172, 15.04%). The results are presented in Multimedia Appendix 6.

Note that it is possible for a person to have multiple accounts or to incorrectly state their hometown, and the poll sample may overrepresent social media users. Data on the number of network nodes for each town and corresponding population census figures are presented in Multimedia Appendix 3.

Main Variables

The main variables of interest are the proportion of known fake and true statements about COVID-19, and the sum of attitudes toward fake and true statements. Additionally, a measure of polarization was constructed.

The control variables are social media usage (VK) and network size. Individual-level controls include gender (dummy), education level, household income, age, fear of COVID-19, a dummy variable indicating household experience with COVID-19, and institutional trust measured as trust in the president. The analysis also controls for television use, as these variables have been used in previous studies on attitudes toward COVID-19 beliefs [6,50]. At the town level, the analysis controls for the natural logarithm of average wage (2019) and the natural logarithm of population (2019). Descriptive statistics for all variables are provided in Table 2.

This study combines individual-level survey data from towns with the network characteristics of those towns. It is assumed that individuals from the same town are influenced by the characteristics of that town's network, as constructed from VK data. A weaker assumption is that differences in VK users' network structures reflect underlying mechanisms of network formation, such as social capital [62]. The estimates are therefore conservative—the study assumes that all respondents are equally affected by the level of fragmentation in their town. In the descriptive statistics (Table 2), town-level characteristics are weighted by the number of respondents in each town; such variables are marked accordingly.

XSL•FO
RenderX

Table 2. Descriptive statistics for used variables (n=16,587).

Statistic	Mean (SD)	Range
Fragmentation index (town level)	0.487 (0.103)	0.293 to 0.799
Gender dummy (1 is female)	0.620 (0.485)	0 to 1
Education level	4.247 (1.055)	1 to 5
Household income group	3.403 (0.820)	1 to 5
Age (years)	36.569 (9.664)	18 to 80
Network size (natural logarithm of the number of nodes; town level)	11.731 (0.790)	5.927 to 13.201
Number of nodes in the network (town level)	155,199.500 (93,322.270)	375 to 541,123
VK use dummy	0.617 (0.486)	0 to 1
Natural logarithm of real wages 2019 (town level)	10.743 (0.147)	10.191 to 11.262
Natural logarithm of population 2019 (town level)	13.310 (0.819)	10.497 to 16.350
Household COVID-19 experience dummy	0.124 (0.330)	0 to 1
Fear of COVID-19	2.936 (0.891)	1 to 4
Trust in president	3.020 (1.466)	1 to 5
Television as a source of news	0.566 (0.496)	0 to 1
Share of encountered fake statements about COVID-19	0.458 (0.286)	0.000 to 1.000
Share of encountered true statements about COVID-19	0.534 (0.257)	0.000 to 1.000
Attitude to true statements about COVID-19	2.143 (2.058)	–8 to 8
Attitude to fake statements about COVID-19	–2.223 (2.792)	–10 to 10
Share of true statements agreed	0.415 (0.257)	0.000 to 1.000
Share of fake statements agreed	0.105 (0.161)	0.000 to 1.000
Difference in attitude between fake and true statements	–4.366 (3.634)	–18 to 12
Misinformation error	0.184 (0.220)	0.000 to 1.750

This section of the paper provides a detailed overview of the primary questions included in the questionnaire used in this study. Table 3 presents the exact translated wording of these key questions. In the first question, which concerns the encounter with true and false statements, respondents are given a list of statements and asked to indicate which ones they have come across, with the option to select “none of the above.” In the following question, respondents are asked to indicate their attitudes toward the plausibility of the statements they had previously selected.

Table 3. Translated wordings of the main questions.

Question number	Question wording
Question 1: knowledge of statements	Select statements that you have previously come across
Question 2: attitude to statements (only for questions that the respondent chooses in the list in previous questions)	Rate your attitude to the following statement (Likert scale from 1 to 4, and difficult to answer): 1=The statement is absolutely NOT reliable; 4=The statement is absolutely reliable.

A measure of the spread of COVID-19–related information and misinformation was created. To do this, the number of encountered statements about COVID-19 was summed and the proportion relative to the total number of statements included in the questionnaire was calculated. These calculations are done separately for true and fake statements. As a result, the proportion of encountered true statements and the proportion of encountered fake statements were obtained. Calculating proportions allows us to consider the full set of statements rather than analyzing each one individually. The relationship between the network’s fragmentation at the town level and the individual-level encounter with information was interpreted as an indicator of the average level of information spread within a city.

To examine whether information exposure translates into differences in beliefs, attitudes toward the statements were calculated. The relevant survey question measures the extent to which respondents believe a given statement is true. Attitudes were quantified by transforming responses on the Likert scale (originally ranging from 1 to 4) to a scale from –2 to +2, but only for the statements the respondent recognized. If a respondent had never encountered a statement or found it difficult to answer, the corresponding value was set to 0. Then, the transformed scores for all true and fake statements were

XSL•FO
RenderX

summed separately to form the true attitude and fake attitude variables. These transformations were designed to create an opinion variable that neutralizes agreement and disagreement across statements, while retaining observations even when a respondent skipped or was unsure about a particular item. Descriptive statistics for attitudes toward each statement are provided in Table 4. Statements 1-5 are classified as fake, and statements 6-9 as true.

Table 4. Attitude toward COVID-19 statements (n=16,587).

Statistic	Mean (SD)	Range	Never came across, n
1. COVID-19 does not exist	–1.219 (1.158)	–2 to 2	570
2. COVID-19 was developed by the United States	–0.112 (0.807)	–2 to 2	10,998
3. COVID-19 was developed by China	–0.229 (0.910)	–2 to 2	8775
4. 5G towers affect COVID-19 immunity	–0.448 (0.906)	–2 to 2	11,083
5. COVID-19 development was financed by Bill Gates	–0.214 (0.728)	–2 to 2	12,911
6. Russia has already developed its first vaccine	0.860 (1.096)	–2 to 2	3651
7. The Prime Minister of Russia got sick with COVID-19	0.570 (0.963)	–2 to 2	8497
8. Russian Government manipulates official COVID-19 statistics	0.674 (1.024)	–2 to 2	6161
9. Trump takes hydroxychloroquine to prevent getting COVID-19	0.040 (0.393)	–2 to 2	15,220

The share of statements a respondent agrees with was also calculated. This is done by summing binary variables coded as 1 if the respondent agrees (either strongly or weakly) and 0 if they do not. The total is then divided by the number of true or fake statements, respectively. This variable does not differentiate between strong and weak agreement, as that distinction is already captured by the attitude variable. Instead, it is used to examine whether fragmentation is associated with a higher overall share of agreed-upon statements, regardless of the strength of the respondent's stance.

Finally, to estimate the overall levels of misinformation about COVID-19 associated with fragmentation, 2 additional variables were created. First, a measure of the difference between opinions on true and fake statements was constructed, which captures individual-level polarization in beliefs about COVID-19. Second, a total misinformation error score, defined as the sum of 2 components, was calculated: the share of fake statements a respondent agrees with and the share of true statements they disagree with.

VK use was measured using a binary variable indicating whether a respondent reported using the VK social media platform. Network size was calculated as the natural logarithm of the number of nodes in the combined network for each town. This variable serves as an alternative measure of VK's relative popularity, derived from network data rather than self-reported survey responses or census statistics.

The final model that estimates the association with COVID outcomes is as follows:

$$\text{COVID_outcomes}_i = \alpha + \beta_1\text{Fragmentation}_j + \beta_2\text{VK}_i + \text{Controls}_i + \text{Controls}_j + \varepsilon_i$$

where i is the respondent from town j; COVID_outcomes_i is the share of known statements, attitude measures, differences in attitude toward true and fake statements, and misinformation error; Fragmentation_j is a town-level fragmentation measure; VK_i is a dummy for VK online social media usage; Controls_i is a set of individual controls; and Controls_j is a set of town-level controls.

The model assumes that the estimated value of the fragmentation index is uniform across all respondents within a given town. The relationship between fragmentation and individual responses is treated as linear, allowing us to estimate the average effect of fragmentation at the town level. While this study does not differentiate the effects of network fragmentation between VK users and nonusers, it does estimate the direct effects of VK usage separately.

Ethical Considerations

Only public information was collected from social media for this study. All relevant information about social networks is presented in an aggregated form and users cannot be reidentified. The survey used in the study was approved by the Columbia Institutional Review Board (protocol number IRB-AAAT4453).

Results

Overview

The results are presented in 2 sections: (1) the relationship between fragmentation and the spread of information, and (2) the relationship between fragmentation and attitudes toward statements. The first section demonstrates that network fragmentation is associated with differential patterns in the dissemination of true versus false statements. The second section highlights how fragmentation contributes to a widening gap between belief in misinformation and agreement with accurate statements about COVID-19, suggesting that fragmented online social networks play a role in shaping polarized beliefs.

The observed effect is primarily driven by a strong negative association between network fragmentation and attitudes toward true statements about COVID-19, while the coefficient for attitudes toward fake statements is statistically insignificant (P=.55).

XSL•FO
RenderX

Part 1: Fragmentation and Information Spreading

Results in Table 5 indicate that the fragmentation index is positively associated with the number of encountered fake statements and negatively associated with the number of encountered true statements. Both findings support the initial hypotheses regarding the relationship between tie strength and information diffusion. Although the estimated coefficients are relatively small, they apply uniformly to all individuals within a given town. An increase in fragmentation from the lowest to the highest level observed in the sample would result in a 0.028 increase in the proportion of known fake statements—equivalent to approximately 64% (0.028/0.044) of the estimated effect of VK social media use. For true statements, the effect is even more pronounced, with a coefficient of –0.034, which exceeds the estimated effect of social media usage. Notably, the coefficients for VK social media use are both significant (P<.001) and positive, suggesting that online platforms facilitate the dissemination of information, regardless of its veracity.

Table 5. Information spreading.[a,b,c]

Information spread	Dependent variables	
	Share of encountered fake statements about COVID-19	Share of encountered true statements about COVID-19
Fragmentation index	0.057 (0.028); .04	–0.068 (0.025); .006
Size of the network	–0.016 (0.004); <.001	–0.004 (0.003); .18
Vkontakte use dummy	0.044 (0.005); <.001	0.030 (0.004); <.001
Socioeconomic town-level controls[d]	+	+
Individual-level controls[e]	+	+
Observations, n	16,587	16,587
R^2	0.018	0.037

[a]Data for the first 3 rows are presented as estimated β coefficients of linear regression (SE); *P* value.

[b]Exact *P* values are reported.

[c]Robust SEs by town are given in brackets.

[d]Socioeconomic town-level controls include the natural log of wages 2019 and the natural log of population 2019.

[e]Individual-level controls include gender dummy, education level, household income, age, fear of COVID-19, a dummy variable for household experience with COVID-19, institutional trust measured as a trust to the president, and use of television.

Part 2: Fragmentation and Attitude Toward Statements

Columns 1 and 2 of Table 6 show that fragmentation is associated with a lower average attitude toward true statements, while no significant relationship is observed for fake statements (P=.55). These serve as the baseline results for the association between network fragmentation and belief in true and fake COVID-19 statements. However, a more nuanced analysis is needed to understand the specific ways in which fragmentation influences belief. In particular, it is important to differentiate between respondents who moderately agree with several statements and those who strongly agree with only one. To capture this distinction, this study uses the share of statements with which a respondent agrees as an additional measure in the estimation.

If we look into columns 3 and 4, we observe that, for true statements, fragmentation leads to a lower share of people agreeing with true statements, but shows an insignificant relationship for fake statements (P=.12). Also, we observe that social media use is significantly negatively associated with attitude toward fake statements (P<.001), but at the same time, it is positively associated with the share of fake statements the respondent believes are true.

The difference in results between true and fake statements can be explained by the idea of ideological distance. When fake news spreads beyond its bubble of believers, it is eventually observed by those who hold different prior beliefs or have been exposed to different information. This leads to double-checking by people outside the initial bubble, which results in a stronger antifake stance. In other words, in more fragmented towns, fake news is spread more widely, but it does not translate into changes in beliefs. Similarly, VK users have a significantly lower average attitude toward fake news but agree with a higher share of fake statements. The result for VK use corresponds with the findings of Bursztyn et al [63], who show that VK use leads to greater variation in beliefs. While they attribute this to network echo-chamber effects, the relationship may be more complex, as no significant relationship was found between network fragmentation and the popularity of extreme opinions about COVID-19.

When looking at the combined results for differences in opinions about fake and true statements, polarization introduced by fragmentation was observed. Column 5 shows the difference between respondents' views regarding fake and true statements. A change in fragmentation from the lowest level (Kostroma) in the sample to the highest (Astrakhan) is associated with a 0.5-point increase in the difference between attitudes. This corresponds to a nearly 14% (0.5/3.64) increase relative to the SD of the variable. At the same time, VK use decreases polarization, although the coefficient is smaller.

XSL•FO
RenderX

Finally, column 6 shows that fragmentation is positively associated with misinformation error—that is, agreeing with untrue statements and disagreeing with true statements. This indicates that, while the overall difference in attitude toward fake statements is indistinguishable from 0 (column 2), fragmentation leads to errors in respondents' ability to distinguish between true and fake statements. VK use is also positively associated with misinformation errors, suggesting that people on online social media are less likely to distinguish fake news from real.

Summing up the results, the findings show that fragmentation is associated with the spread of misinformation and leads to disbelief in true statements, greater polarization of opinions, and increased misinformation errors.

Table 6. Relationship between the fragmentation of networks and attitudes toward statements.[a,b,c]

Statement relationship	Dependent variables					
	Average attitude to true statements about COVID-19	Average attitude to fake statements about COVID-19	Share of true statements agree	Share of fake statements agree	Difference in attitude between fake and true statements	Misinformation error
Fragmentation index	–0.848 (0.194); <.001	0.150 (0.274); .55	–0.102 (0.024); <.001	0.025 (0.016); .12	0.998 (0.355); .005	0.052 (0.022); .02
Size of the network	0.030 (0.027); .27	0.041 (0.038); .28	–0.0001 (0.003); .97	–0.003 (0.002); .13	0.011 (0.050); .82	–0.005 (0.003); .01
Vkontakte use dummy	0.055 (0.034); .10	–0.161 (0.046); <.001	0.022 (0.004); .001	0.006 (0.003); .04	–0.216 (0.060); <.001	0.014 (0.004); <.001

[a]Data for the first 3 rows are presented as estimated β coefficients of linear regression (SE); *P* value.

[b]Exact *P* values are reported.

[c]Robust SEs by town are given in brackets.

[d]Socioeconomic town-level controls include the natural log of wages 2019 and the natural log of population 2019.

[e]Individual-level controls include gender dummy, education level, household income, age, fear of COVID-19, a dummy variable for household experience with COVID-19, institutional trust measured as a trust to the president, and use of television.

Discussion

Principal Findings

This study adds to the body of literature on the COVID-19 infodemic [40,64,65] and health misinformation more broadly [23]. The study's findings show how the characteristics of the network in which an individual is embedded can lead to both polarization and the spread of misinformation. Moreover, network formation itself may be influenced by cultural and social traits of society, such as social capital [62]. This suggests that, more generally, some societies are structurally more prone to misinformation, and that online social media may amplify these effects by reinforcing polarization.

The study shows that social media users are more likely to be aware of both true and fake news, but the association is stronger for fake news. At the same time, social network fragmentation is positively associated with knowledge of fake news and negatively associated with knowledge of true statements. The combined impact of social media use and network fragmentation reveals a difference in the likelihood of encountering true versus fake news about COVID-19. For example, a respondent from the town with the highest fragmentation who uses VK is aware of 7.3% (0.0895-0.0167) more fake statements but 0.4% (–0.0243 to 0.0199) fewer true statements compared with a respondent who does not use social media and lives in the town with the lowest fragmentation. This result provides empirical evidence of differences in the spread of true and fake statements beyond online social media [28].

The study goes beyond medical research and contributes to the literature on the relationship between online social media and ideological polarization. Bursztyn et al [63] proposed a theoretical mechanism explaining how the distribution of preferences shifts with the penetration of social media. The study results align with the model's predictions—echo chamber effects resulting from fragmentation increase ideological distance in opinions about true and fake statements. At the same time, social media use reduces this distance. Thus, the study offers a potential mechanism through which social media penetration leads to polarization. In fragmented networks, echo chambers are more prominent, which amplifies differences in opinions. As a result, the effects of online social network usage may be more constrained when accounting for the structure of such networks.

XSL•FO
RenderX

The study findings highlight the distinction between the effects of online social media use and those of social network structure. Previously, the effects of social media use and social media penetration were often interpreted as consequences of social media bubbles [63]. These are distinguishable correlations that can move in different directions. However, understanding the interrelation between social media use (or penetration) and network structure was beyond the scope of this study and should be explored in future research.

The results presented provide an important bridge between studies focusing on the spread of misinformation within online social media and those examining the propagation of fake news in society more broadly. It was also shown that the fragmentation of online social networks influences the average opinion of individuals within the same town—a result that was overlooked in previous research on this topic [36,65].

However, the findings do not control for active engagement with COVID-19 news. While the study analysis controls for household experience with COVID-19, institutional trust, and fear of COVID-19—which may partially account for active news consumption and abstention—there is evidence of personal network effects on news abstention related to COVID-19 [66]. Part of the results may thus reflect network effects on abstention; that is, in certain networks, individuals may be less willing to discuss specific topics. The study hypothesized that such situations are more likely in smaller networks, where each tie holds relatively greater value. However, the study findings show that network size, if anything, is negatively associated with the popularity of fake statements. This suggests that people in smaller towns are not necessarily more likely to abstain from discussing COVID-19.

Limitations

This study had several limitations, which the author attempted to address and clarify in terms of their potential impact on the results. First, the network data were collected in 2023, whereas the survey was conducted in 2020. This time gap introduces a measurement error bias, which likely reduces the statistical significance of the results [67]. Additionally, the method used for sampling networks has limitations, as discussed in the "About VK" section. The study assumes that connections between accounts persist over time and that there has been no substantial drift in the fragmentation of towns—an assumption necessary for interpreting the observed correlations. Moreover, VK social networks are not representative of the entire population and do not capture all social interactions among Russian citizens. To estimate the potential bias introduced by using VK networks as a proxy for actual social interaction networks, demographic data from VK accounts and survey responses were compared. This information is provided in Multimedia Appendix 7. A similar age and gender structure was observed between the 2 groups, but there was a substantial difference in the proportion of individuals with higher education. The survey data likely overrepresent individuals with higher education compared with the general population. Additionally, users with higher education may not consistently disclose their educational background on VK, as this information is not required to use the platform. Importantly, this research does not claim a causal relationship between fragmentation and the spread of conspiracy theories.

To partially test the assumption of network structure stability, additional data in June 2023 and January 2024 (a 7- and 11-month gap, respectively) were collected. The results of the paired *t* test are presented in Multimedia Appendix 4. No significant differences in town-level fragmentation were found between 2023 and 2024. This suggests that network structure is either persistent over time or shaped by stable societal traits. While network scientists have increasingly focused on the emotional aspects of social ties, the formation of social ties and network structures remains understudied [68]. Social scientists often link network structure to generalized trust, a key component of social capital [62], and generalized trust is known to be stable over long periods [69]. Therefore, even if the 2023 fragmentation measure does not serve as a perfect proxy for actual fragmentation in 2020, it likely still captures elements of social capital that are persistent over time.

A robustness check was conducted using a subsample of towns with higher edge coverage. Previous research has indicated that an edge coverage of 15% yields a network sample that effectively preserves its structural characteristics [60]. This study analyzed a sample of 149 towns, excluding those with the lowest edge coverage, as they are more prone to bias. This adjustment increased the average edge coverage from 12.72% (688,859/5,416,402) to 15.04% (739,677/4,917,172). The results of these robustness checks are presented in Multimedia Appendix 6. The main outcomes discussed in this study remain robust even after excluding towns that may produce biased estimates of network variables.

Conclusions

The results presented are particularly relevant in the context of the increasing spread of fake news, misinformation, and disinformation. They suggest that it is not only the sources of information that matter but also the structure of interpersonal networks. More broadly, these findings highlight the critical role of social networks in the dissemination of information.

This study demonstrates the indirect effects of online social media structures on the spread of both information and misinformation about COVID-19, as well as on changes in public attitudes. The results underscore the relative importance of the social networks individuals belong to and how information flows through these networks.

For future research, it is important to develop a clearer understanding of the mechanisms linking social media use, personal networks, and town-level modularity to fully capture the multilevel effects of social media on the spread of misinformation and attitudes toward it. Additionally, future studies should consider using more advanced methods of network sampling.

Abstract

Background: Many women with breast cancer document their experiences in YouTube vlogs, which may serve as peer-to-peer and community support.

Objective: This study aimed to determine (1) the forms of content about breast cancer that tend to be discussed in vlogs, (2) the reasons why women choose to vlog their breast cancer experiences, and (3) the potential for breast cancer vlogs to serve as an alternative or complement to peer-to-peer support as well as a site of digital community overall.

Methods: YouTube was searched in incognito mode in November 2023 using the search terms “breast cancer vlog.” A maximum of 10 videos/creator were included based on viewership and date created. Video characteristics collected included title; length; number of views, likes, comments; and playlist inclusion. Videos were assessed for sponsorship; presence of explanation and discussion on breast cancer; type of content; and themes. Creator characteristics included age, location, and engagement approaches. Descriptive and content analyses were performed to analyze video content and potential areas where peer-to-peer support may be provided.

Results: Ninety vlogs by 13 creators were included, all from personal accounts. The mean (SD) video length, number of views, and number of comments were 21.4 (9.1) minutes, 266,780 (534,465), and 1485 (3422), respectively. Of the 90 videos, 35 (39%) included hashtags, and 11 (12%) included paid sponsorships. The most common filming location was the home (87/90; 97%), followed by the hospital (28/90; 31%) and car (19/90; 21%). Home vlogs were most often set in the living room (43/90; 44%), bedroom (32/90; 33%), or kitchen (20/90; 21%). Thirty-four of 60 videos (57%) included treatment visuals and physical findings. Creators addressed motivation for vlogging in 44/90 videos (49%); the two most common reasons were wanting to build a community and helping others. In 42/90 videos (47%), creators explicitly expressed emotion. Most common themes were treatment (77/90; 86%), mental health (73/90; 81%), adverse effects (65/90; 72%), appearance (57/90; 63%), and family relationships (33/90; 37%). Patient-directed advice was offered in 52/90 videos (58%), mostly on treatment-related issues. In 51/90 videos (57%), creators provided explicit treatment definitions. Chemotherapy was discussed in 63/90 videos (70%); surgery in 52/90 (58%), primarily mastectomy; radiation in 27/90 (30%); and general adverse effects in 64/90 (71%). Twenty-two of 90 videos (24%) were about a new diagnosis. When mentioned (40/90; 44%), the most common creator location was the United States. When mentioned (27/90; 30%), the most common age was 20 - 29 years.

Conclusions: The dedication to building community support by vlog creators, and the personal nature of their storytelling, may make vlogs a potential resource for peer-to-peer support.

Introduction

Vlogs, or "video blogs," are personally and individually created experiential videos based on wide-ranging topics, usually posted to YouTube. A popular subset of vlogs are created by women with breast cancer, in which they document their breast cancer experiences in a publicly accessible digital format. As videos that tend to invite viewers into the lives of their creators, vlogs typically receive high levels of engagement and draw audiences who will continue watching in order to keep up with what creators are doing next. Online tools such as these vlogs are important parts of patients' experience with processing and managing chronic illness [1]. They can help patients find support, community, and information in spaces they may not have access to in real life [2]. Overall, social support is a prominent theme in literature about breast cancer communication on social media [2].

YouTube is growing as a source of "peer-to-peer health information sharing and support" [3]. The importance of peer support across cancer is widely acknowledged [4]. Breast cancer peer support programs have been shown to be effective in enhancing patients' quality of life [5], particularly regarding the alleviation of depression and anxiety [6]. Moreover, peer programs are similarly shown to be successful in providing emotional and psychosocial support [7]. Patient support groups can fulfill patient needs and improve quality of life [6,8,9]. Peer education was also found to reduce levels of psychological pain [10]. Research demonstrates that women with breast cancer need and expect online support programs, despite platform-related challenges such as inconsistent content moderation and that "well-organized and tailored" peer support is important to enhance their quality of life [11].

While vlogs about breast cancer may have the potential to serve as peer-to-peer support and provide community, their content, quality, and role in the breast cancer experience are understudied. The objectives of this study were to (1) determine what forms of content about breast cancer tend to be discussed in vlogs, (2) inquire into the reasons why women choose to vlog their breast cancer experiences, and (3) consider the potential for breast cancer vlogs to serve as an alternative or complement to peer-to-peer support, as well as a site of digital community overall.

Methods

Study Design

YouTube was searched in incognito mode in November 2023, using the search terms "breast cancer vlog." Breast cancer vlog creators were identified, and their video characteristics were collected. If the creator produced less than 10 videos, all were included. If they produced more than 10, a maximum of 10 were included, based on viewership and most recent date created. Creators were identified based on whether they produced English-language breast cancer-related videos in the last 5 years. Prior to evaluating the videos in this dataset, reviewers were trained to collect vlog data using a standardized data collection tool. A sample was collected, and data collection quality, as well as procedures for any disagreement in evaluations, were assessed before initiating the formal data collection.

Reviewers collected creator information (ie, age, location, profession, and cancer stage). They collected the video titles; length; date; number of views, likes, and comments; and hashtags; and noted whether the videos were part of a playlist. Reviewers then assessed videos based on consumer details (ie, sponsorships, product recommendations, and endorsements), and the creators' explanations and discussions of their breast cancer. Engagement levels were considered based on vlog creators' discussion with their audience, whether they commented on their experience with their audience, or asked the audience to share insights of their own. Types of content (diagnosis, surgery, or other event) were also collected.

Video themes were extracted both deductively and inductively. The themes collected deductively are described in Table 1. Descriptive and content analyses were performed to assess and analyze video content and potential areas where peer-to-peer support may be provided. Reviewers were encouraged to add subthemes inductively in cases where the content exceeded or was more specific than the deductive themes [12]. An additional set of questions was applied to videos that contained advice, in order to characterize the nature, source, and potential validity of the advice provided (Table 2).

XSL•FO
RenderX

Table . Deductive themes.

Theme	Definition
Appearance	Refers to one's experiences with their appearance, including how it may have changed over the course of treatment
Mental health	Refers to questions of mental health, including stress, anxiety, depression, or other related issues
Fear of recurrence	Refers to fears or anxieties related to the future possibility of a cancer recurrence
Gender identity	Refers to one's gender identity, particularly in the context of breast surgery or reconstruction choices
Sexuality	Refers to experiences of sexual intimacy, including how these may have changed over the course of treatment
Fertility	Refers to one's experiences with fertility or infertility, including fertility treatment
Motherhood	Refers to the specific relationship between mother and child, how to disclose to one's children, as well as wanting to be a mother
Spousal relationship	Refers to the patient's relationship with their spouse, including stress on the spouse who takes on a caregiving role
Family relationship	Refers to family-based experiences, such as how one may disclose their diagnosis to their family and how a diagnosis shifts the family dynamic
Path to diagnosis	Refers to the story or experience of being diagnosed with breast cancer, such as discovering a breast lump
Treatment	Refers to a wide array of topics, ranging from treatment choices to the experience of receiving treatment
Adverse effects	Refers to specific experiences with adverse effects, whether due to surgery, chemotherapy, or other forms of treatment

Table . Advice assessment.

Characteristic	Definition
Vlog creator verbalizes a reference or source for advice.	Refers to the vlog creator verbally explaining where or from whom they learned about the advice provided.
Vlog creator confirms having tried the advice personally.	Refers to the vlog creator describing their own personal experience by following the advice provided.
Proposed advice recommends adding something (addition) or not doing something (omission).	Refers to whether the vlog creator suggests making some sort of addition to their care or cancer management or ceasing or removing an aspect of their care or cancer management.
Proposed advice involves a product to be applied or consumed.	Refers to whether the proposed advice involves applying or consuming a product.
Proposed advice suggests a modification or reduction in the treatment plan.	Refers to whether the proposed advice suggests some sort of modification to or reduction in one's cancer care management or treatment plan.
Proposed advice is potentially beneficial, neutral, or potentially harmful.	Refers to whether the advice provided is of potential benefit to a patient, neutral, or of potential harm to a patient.

Ethical Considerations

Institutional ethics review was not required for the completion of the study, as all the data including patient- and disease-specific information and opinions or experiences were volunteered into the public domain by the creators. No patient- or disease-specific information was collected. No identifiable information is published.

Results

A total of 90 vlogs by 13 vlog creators were included in the study, all of which originated from personal YouTube accounts. The mean (SD) video length was 21.4 (9.1) minutes. The mean (SD) number of views was 266,780 (534,465). The mean (SD) number of comments was 1485 (3422). Hashtags—words or phrases preceded by the "#" symbol that serve to categorize social media content—were included in 35 videos (39%), the majority of which were breast cancer-related. Paid sponsorships were present in 11 videos (12%). Creators promoted their own

XSL•FO
RenderX

channel in a large majority of videos (80/90; 89%); for instance, by encouraging channel subscriptions. Most creators (88/90; 98%) included a title that effectively summarized the video topic, meaning that the title described the events discussed in the video. Where mentioned, the range of 20 - 29 years was the most common age group (14/27; 52%), followed by 30 - 39 years (10/27; 37%). Where mentioned, the most common creator location was the United States of America (25/40; 62%).

Visuals were present in 60/90 videos (67%); of these 60 videos, 34 (57%) included images or videos of vlog creators undergoing treatment (such as receiving chemotherapy or radiation, or undergoing magnetic resonance imaging) as well as physical features of treatment, including port scars, surgical drains, and breast contour after expander placement. A portion of videos (36/90; 40%) included inserted recorded clips, for instance, playing a recording of a phone call with their pathologist discussing results or footage of entering the radiation machine.

Videos were mainly filmed at home (87/90; 97%), at the hospital (28/90; 31%), or in the car (19/90; 21%). It is possible that vlogs were filmed in more than one setting. When filmed at home, vlogs were most often set in the creator's living room (43/90; 44%), bedroom (32/90; 33%), or kitchen or office (both 20/90; 21%).

In half of the vlogs (45/90, 50%), the creator commented on how their audience makes them feel, and in 44/90 (49%), the creator explained why they decided to make vlogs about their breast cancer experience, the most frequent reasons being: (1) enjoying filming vlogs, (2) wanting to build a community, (3) having a predominantly female viewership, (4) wanting others with cancer to feel less alone, (5) sharing information on surgery, and (6) providing details about signs of their recurrence. For example, one vlog creator described the process of filming and posting vlogs about her metastatic breast cancer as therapeutic "because it feels like she sat and talked to someone about everything on her mind"; this creator also referred to the viewers who have expressed that her vlogs helped them through their own experiences as making her feel like her vlogs have a purpose. It is important to her that her audience—specifically, others facing a similar diagnosis—knows that they are "not alone in this at all." In 42/90 videos (47%), creators expressed emotion in an explicit way; for instance, one vlog creator filmed her last chemotherapy treatment and was emotional while ringing the celebratory bell and thanking her nurses.

Advice was offered in 52/90 (58%) videos, with the most common topics being cold capping, hair regrowth, clothing, nutrition, mental health habits, chemotherapy preparation, saline soaking for radiation burns, wig use, and cancer prevention. References or sources were rarely cited, with advice usually originating from the video creator themselves. In most cases, the creator confirmed the advice was based on their personal experience. Advice overwhelmingly involved making some sort of addition to one's care or cancer management rather than an omission. None of the proposed advice was considered of potential harm to patients. Additional details on videos containing advice are outlined in Table 3.

Table . Advice provided in vlogs.

Characteristic	Frequency (%)	Example
Vlog creator verbalizes a reference or source for advice.	• Yes: 3 (5%) • No: 49 (95%)	Friend, website, or book
Vlog creator confirms having tried the advice personally.	• Yes: 42 (81%) • No: 10 (19%)	N/A[a]
Proposed advice recommends adding something (addition) or not doing something (omission).	• Yes: 51 (98%) • No: 1 (2%)	Cold capping, purchasing products, stretching, attending therapy sessions, using sleep aids, maintaining a positive outlook, or praying
Proposed advice involves a product to be applied or consumed.	• Yes: 15 (20%) • No: 37 (80%)	Vaseline, compression socks, ginger supplement, cold capping equipment, hair or beauty products, blankets, or pajamas
Proposed advice suggests a modification or reduction in the treatment plan.	• Yes: 14 (27%) • No: 38 (73%)	Modifying chemotherapy administration method by using a port-a-cath instead of a peripheral venous infusion
Proposed advice is potentially beneficial, neutral, or potentially harmful.	• Harmful: 0% • Neutral: 24 (46%) • Potentially beneficial: 28 (54%)	Reduced risk of deep vein thrombosis, reduced hair loss, and reduced diarrhea

[a]N/A: not applicable.

Where the cancer stage was mentioned, stage IV was most common (13/90; 14%). Of the 90 videos, 22 (24%) were about a new diagnosis. Chemotherapy was the predominant treatment form discussed in the majority of videos (63/90, 70%); surgery in 58% (52/90), primarily mastectomy (20/52, 38%); and radiation in 30% (27/90). The general adverse effects were discussed in 71% of the videos (64/90). In over half of the videos (50/90; 57%), creators provided a structured definition to some aspect of their treatment.

The most common themes were treatment (77/90; 86%), mental health (73/90; 81%), adverse effects (65/90; 72%), appearance (57/90; 63%), and family relationships (33/90; 37%). Subthemes included young age, finances, the importance of online

XSL•FO
RenderX

community support, social life, fear of surgery, egg retrieval, and confidence and redefining beauty standards.

Discussion

Principal Findings and Comparison With Previous Works

This study demonstrates that vlogs by women with breast cancer receive significant levels of engagement and represent an important site of online community for women. However, the nature of their content, their authorship, and the potential to be integrated into care plans are underexplored. Our study shows that most commonly discussed themes in breast cancer vlogs include treatment, mental health, adverse effects, and appearance, but that a wide range of subthemes are also present. Moreover, they are often filmed in a personal home setting. These patient-created videos, which included less paid sponsorship than what researchers have identified in previous analyses [12], included detailed and overt expressions about why creating vlogs about their breast cancer is a valuable experience. The production behind vlogs, combined with the settings in which they are filmed, contribute to the feeling of connection between the creator and the audience. That vlogs are often filmed at home may be important to building a sense of community. The seemingly close and casual environment of filming in one's own living room or bedroom creates a sense of proximity to the vlog creator that is more aligned with the support group model that might not necessarily be present in a professional setting.

There is a rich community-centered aspect to breast cancer vlogs, which may position them as complementary forms of peer-to-peer social support and as unique methods for effective coping. Tailoring peer support to the moments when patients are most in need is crucial [13]. In their study on factors of engagement and patient-reported outcomes in a stage IV breast cancer Facebook group, Kashian and Jacobson [14] conclude, "Optimal social support plays a critical role facilitating engagement in online breast cancer support groups. It is not enough that members exchange social support in online support groups, rather members must exchange the type of support that facilitates effective coping." Power and Hegarty [15] also found that support programs need to be tailored to the needs of women with breast cancer and have identified "the need to allow more informal sharing to occur in facilitated peer support programs." Vlogs are easily findable and watchable. While different peer support models and approaches will have varying outcomes on different patients, web-based support without training and/or moderation should be used with caution [16]. YouTube is heavily engaged with for public health reasons. However, there is a need for higher-quality content [17]. Research evaluating YouTube videos about radiotherapy in breast cancer concludes that while videos were inconsistent in following best practice guidelines, YouTube still has potential toward disseminating health information [18]. Research on YouTube videos about radiotherapy in lung cancer draw similar conclusions [19].

It is possible that informal sharing also happens in online spaces, where patients might feel they have more control over how much they can share and can do so in the format, style, narrative, and medium of their choosing. Ziegler and colleagues [20] have shown a moderate positive association between peer support and psychological improvement in cancer patients. People who post and share about their experiences in online communities are not the only ones who benefit from the peer support in these spaces; research shows that "lurkers," or those who watch or consume content without sharing their own, can also benefit from the advice and insights shared [21]. Many messages in online support groups are requests for information and opinion from those in the same situation and are designed to reach like-minded people [22]. These networks are informal, grow organically, and are accessed when needed.

The use of visuals and additional recorded clips in vlogs, such as the inserted phone recordings or hospital footage, may contribute to a sense of closeness between the creator and their audience. Such instances of additional video editing are indications of vlog creators' platform expertise and demonstrate the production efforts behind vlog creation [23]. However, in the context of documenting one's breast cancer experiences, additional video editing may actually serve to provide even more detail for one's audience: playing a phone recording or showing hospital footage (of, for instance, receiving chemotherapy infusions) allows the audience to see and hear parts of the creator's breast cancer experience that they were not present for, thereby creating a further sense of closeness with the creator. Inviting one's audience into private hospital or clinical encounters also holds implications for standardized practices of medical confidentiality. For these creators, there is something important about sharing what tends to be considered private. The perceived closeness afforded by hospital footage and recorded phone calls, for example, may also serve to demystify these experiences for audience members who might be about to begin their own breast cancer treatment. In this context, typical conceptions of what is considered public or private are blurred, and viewers may begin to develop emotional bonds with vloggers they have never met: a phenomenon not unique to vlogs about breast cancer, but which occurs across different types of social media content and platforms [24]. Scholars have discussed the notion of the microcelebrity, particularly the ways in which celebrity and fame are connected to different media [25]. Given this context, it is plausible that breast cancer vloggers may achieve certain levels of microcelebrity status on YouTube, which may result in a feeling of parasocial closeness—defined as "nonreciprocal socio-emotional connections with media figures such as celebrities or influencers"—on the part of the audience, and which can continue in cases where the video creator dies [26].

Key features of breast cancer vlogs, which include explanations of the diagnosis experience, are associated with receiving empathic support from audiences [27]. The emotionally intense context afforded by the medium of video is demonstrated to lead to community-building and social support among vloggers and their audiences [28]. In their study of breast cancer narratives on social media, Ma and colleagues [29] found, "Stories that were longer, less emotionally intensive, told from the cancer survivor's perspective, with gender identity–related information, describing the act of providing social support, explicitly requesting engagement and/or donation, and using

XSL•FO
RenderX

more vivid forms of visuals such as linked images tended to be more engaging." However, while Ma and colleagues [29] found that emotionally intensive stories may be less engaging, social media research suggests, "Crying and anxiety blogs can function as a means of demonstrating vloggers' 'authenticity,' and thus fostering valuable intimacy between vloggers and their audience" [30]. The sense of intimacy shared by vloggers—especially when demonstrating explicit emotion in their vlogs—is valuable in this context because it serves to develop a bond between the creator and the audience, who may decide to begin regularly following the creator's breast cancer trajectory. In our study, creators explicitly expressed emotion in almost half of the videos. Emotion is an important part of the breast cancer stories that vlog creators tell, and it resonates with their audiences: several videos in this dataset, particularly those relating to metastatic disease and end of life, were challenging for reviewers to watch and remained distinctly memorable after data collection was completed. The vulnerability and emotion present in these vlogs—and thus, their relatability—may provide a form of connection between creator and audience that health care professionals cannot provide due to the objectivity they have to maintain in delivering care.

Vlogging about breast cancer may also hold therapeutic value [31]. Creators in this dataset have discussed what they perceive to be the benefits of vlogging, among which is the idea that vlogging is a way to speak about everything on their minds, not unlike sitting and chatting with someone. When creators hear from their audience that watching their vlogs helped them to feel less alone, or helped them in their own journeys, they express that this audience response helps them to feel like their vlogs have a purpose. Vlogs are a source of support and can help patients cope with isolation not only in dealing with cancer, but also with other chronic illnesses such as fibromyalgia, diabetes, and HIV [32-34]. The value of vlogging about breast cancer can extend beyond patient communities to health care settings; one reviewer, a surgical resident, commented that watching the vlogs in this dataset was important to their training experience. For this reviewer, seeing how patients understand the course of their treatment as explained to them by their doctor/surgeon, what they focus on, what they fear, and how they take the information they have received and share it in a digestible way with their viewers was very useful, and would contribute to how they engage with cancer patients going forward. In this way, watching vlogs may also hold value in medical training settings, as examples of voluntarily provided patient experience.

Questions of how to handle the transfer of information in vlogs were considered throughout this study's design. In some cases, reviewers were able to anecdotally or casually identify some vloggers who provided high-quality explanations of their cancer and its treatment, to the point that the reviewer would suggest it to their patients if needed. That being said, it is challenging even for health care professionals to evaluate the quality of information as it is presented intertwined with personal experiences (often indistinguishable) in experience-based videos. Validated tools for evaluating YouTube video quality now exist; however, Gabarron and colleagues [35] demonstrated, in their 2013 review, that as recently as 10 years ago, guidelines for such evaluations were "unclear and not standardized." While standardized instruments such as the DISCERN tool and the Patient Education Materials Assessment Tool can be used to evaluate different forms of media, their applicability is limited in regards to patient-created, experiential content. Vlogs are an experience-based media format grounded in personal storytelling, where it is often difficult to distinguish information from advice or lived experience. As such, the goals behind both creating vlogs and watching them may be more closely related primarily to building and seeking forms of community and connection, rather than imparting information or learning about medical facts. Nevertheless, our assessment revealed that the majority of advice offered in vlogs consisted of patient-centered concerns and personal preferences that were unlikely to affect cancer treatment trajectories. The proposed advice was not found to be of potential harm to patients (even if questionably beneficial) and was largely experiential.

Limitations

The limitations of this study include restrictions based on language and challenges related to collecting demographic data. This study was limited to English-speaking videos, which may influence views or perceptions of the breast cancer experience. In addition, because vloggers may or may not disclose specific information such as their age, nationality, location, profession, or cancer stage, the consistent collection of these data points was not possible. Future research on breast cancer vlogging practices in specific linguistic, geographic, or ethno-cultural communities represents an opportunity to understand the circulation of health information within communities that may not have easy access to mainstream health services. While some of the peer support literature cited in this paper predates the development and widespread use of social media, the authors contend that this earlier foundational literature functions as a precursor to contemporary understandings of the benefits of social media communities, their effects on patients' outlooks, as well as their reasons for participating in them.

Given that the purpose of vlogging is not to educate one's peers but to share experiences and build an online community, the potential for using currently existing standardized tools to assess information quality is limited. In light of the growth of online peer-support communities and the lack of methodology regarding the quality and accuracy of information that is woven into patient experiences reported in the vlog format, there is a need for the development of a methodology that specifically validates the quality of information transferred in these settings. The next phase of our research will address breast cancer vlogs, and other cancer-related media content, created by and from the perspectives of health care professionals where, in contrast, health care professionals have a primary goal of transferring information to support patients. Future research may evaluate the differences in engagement metrics (such as views, likes, or comments) between breast cancer video content created by patients for patients and content created by health care professionals.

Conclusion

This study demonstrated that the awareness of and dedication to building community that vlog creators show in this context,

XSL•FO
RenderX

as well as the personal nature of their storytelling, their advice and suggestions, and their discussions of wide-ranging yet specific topics all position vlogs by women with breast cancer as a potential resource for peer-to-peer support in breast cancer. The experiences of both creating and watching breast cancer vlogs hold significant potential benefits for peer-to-peer support in breast cancer care. This study aligns with Kashian and Jacobson's [14] conclusions, which suggest that given the association between optimal social support and community engagement, "Hopefully practitioners will use this information to encourage patients to join quality online support groups for positive experiences." While there are risks associated with consuming online content, the potential benefits of community and support offered by breast cancer vlogs should not be overlooked. Future research will consider patient perspectives and further address how the specific themes discussed in vlogs may be used to improve the cancer care experience for breast cancer and other cancers.

Abstract

Background: Transgender and gender diverse people often turn to online platforms for information and support regarding gender-affirming hormone therapy (GAHT); however, analysis of this social media content remains scarce.

Objective: We characterized GAHT-related videos on TikTok to highlight the implications relevant to GAHT prescribers.

Methods: We used a web scraper to identify TikTok videos posted under the hashtags #genderaffirminghormonetherapy and #genderaffirminghormones as of November 2023. We identified recurrent themes via qualitative content analysis and assessed health education videos with the Patient Education Materials Assessment Tool for Audiovisual Materials (PEMAT-A/V) scale and a modified Currency, Relevance, Authority, Accuracy, and Purpose (CRAAP) test.

Results: Out of 69 videos extracted, 71% (49/69) were created by GAHT users, 24.6% (17/69) were created by health care workers, and 21.7% (15/69) were created to provide health education. Themes included physical changes on testosterone, GAHT access, and combating misinformation and stigma surrounding GAHT. Health education videos scored highly on PEMAT-A/V items assessing understandability (mean 88.3%, SD 11.3%) and lower on actionability (mean 60.0%, SD 45.8%). On the CRAAP test, videos scored highly on the relevance, authority, and purpose domains but lower on the currency and accuracy domains.

Conclusions: Discussions of GAHT on TikTok build community among transgender and gender diverse users, provide a platform for digital activism and resistance against legislation that limits GAHT access, and foster patient-provider dialogue. Educational videos are highly understandable and are created by reliable sources, but they vary in terms of currency and quality of supporting evidence, and they lack in actionability.

Introduction

TikTok (ByteDance) is a short-form video-sharing application that boasts 97.6 million active users in the United States. Since TikTok's spike in popularity in 2020, transgender and gender diverse (TGD) content creators have used the platform as a space to document and share their experiences with others. While TikTok has the potential to disseminate health information and improve access to gender-affirming care, it has come under scrutiny for spreading misinformation, bias, and hate speech [1].

Despite the lack of systematic analysis, the spread of information about gender-affirming care within the TGD TikTok community has been cited as an example of community-engaged knowledge exchange and peer-to-peer support [2]. Furthermore, TikTok has the potential to improve access to health information among communities that experience health inequities as the result of

XSL•FO
RenderX

discrimination, because having positive impressions of knowledgeable professionals on social media may help decrease medical mistrust and enhance access to care offline [2]. Lowering medical mistrust among TGD communities is crucial, given that 24% of respondents in the 2022 US Transgender Survey reported avoiding medical care due to fear of mistreatment by a provider [3].

While TikTok videos have the potential to improve access to health information, peer support, and trust in medical professionals, TikTok may also be used to spread misinformation, disinformation, and hateful rhetoric against lesbian, gay, bisexual, transgender, queer, intersex, and all asexually and gender diverse (LGBTQIA+) people on the platform [4]. For example, the use of gender-affirming hormone therapy (GAHT), which involves administering hormones like estrogen and testosterone or puberty blockers to alter gendered physical characteristics among TGD youth, has increasingly been attacked; its controversy has led to online hate speech and, in several instances, threats of violence against hospitals and individual providers online [5,6].

Previous studies have queried TikTok to explore attitudes toward and experiences with other types of medical care, using qualitative methods to determine the content and tone of posts about medical interventions ranging from contraceptive methods to erectile dysfunction treatment [7-9]. Others have focused on analyzing the quality and accuracy of health information reported on the platform [10-15]. Their analyses yielded insights into misconceptions about care, the prevalence of inaccurate factual claims about treatment, and salient elements of individual experiences with care, all of which have the potential to inform how clinicians treat and counsel their patients. However, there have been no analyses of users' attitudes towards, experience with, or knowledge about GAHT.

The aim of this study is to explore popular TikTok content posted under the hashtags #genderaffirminghormones and #genderaffirminghormonetherapy. Using previously validated methods, we (1) describe the demographic characteristics, attitudes, and affiliations of video content creators; (2) perform a qualitative analysis of video content to identify content themes; and (3) assess the understandability, actionability, and reliability of information presented in a subset of educational videos. In doing so, we aim to better understand the degree to which TikTok is a vehicle for sharing valuable information about GAHT and treatment access versus a potentiator of misinformation and harmful biases.

Methods

Data Extraction

We used the web-scraping application Apify (Apify Technologies s.r.o.) TikTok scraper to download all TikTok videos posted publicly under the hashtags #genderaffirminghormonetherapy and #genderaffirminghormones as of November 17, 2023; Apify provided all videos as MP4 files. While videos that fit the inclusion criteria may be available under alternate hashtags, only these two hashtags were selected for this study, as it was infeasible to scrape the vast content created under broader hashtags; additionally, users who are actively seeking information on GAHT would most likely search these two hashtags. The scrape included a total of 86 videos. We applied the following exclusion criteria: (1) non-English language video, (2) country codes in the European Union or China (based on differences in data usage agreements in these regions), (3) GAHT not mentioned in the video, (4) duplicate video, or (5) video posts removed following the scrape.

Descriptive Analysis of the Content

For all eligible videos, we recorded the date posted and video duration, and TikTok engagement statistics, including the number of video views, likes, comments, shares, and number of creator fans. Through discussion and consensus, the first and second authors determined five main categories of videos after reviewing all videos (personal experience, health education, politics, creator opinion, and humor) and categorized each video. The sum, median, and IQR of engagement statistics were calculated for each type of video to best characterize the distribution of engagement; these metrics were selected given that specific videos may go viral on the platform, thereby skewing the data.

The first author then determined content creator demographics, including self-described gender identity and sexual orientation, for each video via the exploration of content creators' public profiles, including the user, bios, current or previous videos, video captions, and comment responses [16]. Only explicitly stated identities from content creators were included to avoid assumptions about their identities; if no such statements were available, we marked the field as "unknown." We selected "not applicable" if the account belonged to an organization rather than an individual. We similarly obtained creators' GAHT user status, health care worker status, and organizational affiliations from information on their public profiles. Finally, the first and second authors individually rated each video on whether the creator displayed a positive (eg, supportive or encouraging), negative (eg, dismissive or transphobic), neutral (eg, purely informative), or ambiguous or mixed attitude (authors could not ascertain or agree on the creator's intentions) toward GAHT. Through discussion, the authors came to a consensus on the final ratings of all videos.

Quality Rating of the Content

We further analyzed a subset of health education videos to assess the understandability, actionability, and reliability of information presented. "Health education" videos contained at least one message about which creators aimed to inform viewers [17,18].

The first and second authors independently used the Patient Education Materials Assessment Tool for Audiovisual Materials (PEMAT-AV) to assess information understandability (ie, accessibility of the information presented for the layperson, including statements like "The material uses common, everyday language"; items 1 - 13) and actionability (ie, the feasibility of implementing the information presented, including statements like "The material breaks down any action into manageable, explicit steps"; items 14 - 17) of patient educational materials. Each item in the scale is rated as "agree" (1 point), "disagree"

XSL•FO
RenderX

(0 points), or "not applicable." The first and second author then compared each rating they assigned until they came to a consensus on all items. Finally, scores were calculated as a percentage of the possible points obtained for all items, excluding those rated as not applicable. Higher percentages suggest higher levels of understandability and actionability, with a threshold of >75% used to indicate "high quality" [19-21].

The senior author, who is a physician-scientist specialized in gender-affirming care, also used a modified Currency, Relevance, Authority, Accuracy, and Purpose (CRAAP) test to assess the reliability and accuracy of health information presented in educational videos [22]. The CRAAP test is used for the quantitative assessment of digital health information [23-25] by assessing five domains of information reliability: currency, relevance, authority, accuracy, and purpose. We adapted a previously published scale and scoring key by modifying the language and removing several items that were not applicable to audiovisual media [23]. Our adapted scale contained a total of 18 items (3 assessing currency, 4 assessing reliability, 3 assessing authority, 3 assessing accuracy, and 5 assessing purpose).

Overall scores ranged between 0 and 34, with higher scores suggesting higher reliability. Based on previous work using the CRAAP test, we considered a final score of <20% as unreliable, 20 - 46% as reliable with caution, 46 - 80% as good reliability, and >80% as excellent reliability [23]. We used Cronbach α to assess the interitem reliability of the scale (α=.88). The rubric for the modified CRAAP test is provided in Table 1.

XSL•FO
RenderX

Table . Modified Currency, Relevance, Authority, Accuracy, and Purpose (CRAAP)[a] test.

Item	Scoring key			
	0	1	2	3
Currency (3 items, 5 points)				
Date created	>5 y	1 - 5 y	<1 y	N/A[b]
Information outdated or debunked	Yes	No	N/A	N/A
Embedded links or suggested resources still accessible	None listed	No longer accessible	Still accessible	N/A
Relevance (4 items, 4 points)				
Information answers a central question	No	Yes	N/A	N/A
Information identifies an intended audience	No	Yes	N/A	N/A
Information appropriate for the needs of the intended audience	No	Yes	N/A	N/A
Information avoids overgeneralization	No	Yes	N/A	N/A
Authority (3 items, 5 points)				
Identity of the author or source	None identified	Medication user or patient	Expert in the field	N/A
Author's credentials	None	Lived experience	Licensed medical professional	N/A
Author qualified to discuss the topic[c]	No	Yes	N/A	N/A
Accuracy (3 items, 7 points)				
Derivation of information	Unclear	Individual lived experience	Professional experience	Evidence-based review
Is the information supported by evidence[d]	No	Yes	N/A	N/A
What kind of evidence supports the claim	None	Individual lived experience	Expert/consensus opinion	Published evidence-based guidelines
Purpose (5 items, 8 points)				
Purpose of information	Advertisement	Persuading or entertaining	Informing	Teaching
Intentions or purpose clear	No	Yes	N/A	N/A
Nature of information	Propaganda	Opinion	Facts	N/A
Point of view appears objective and impartial	No	Yes	N/A	N/A
Political, ideological, cultural, or religious biases	Yes	No	N/A	N/A

[a]This modified CRAAP Test is developed from the original test by Sarah Blakeslee, which is licensed for adaptations under a Creative Commons Attribution 4.0 International License.

[b]N/A: not applicable

[c]Creators were considered qualified to discuss a topic if they either had confirmed credentials indicating relevant subject matter expertise and licensure relevant to the clinical topic, or lived experience in a patient testimonial.

[d]Information presented in videos was considered supported if contemporary scientific evidence was congruent with the information.

Ethical Considerations

This study involves the analysis of publicly available data from TikTok; data from private accounts were not assessed as part of this project. Investigators only had access to creators' account names while viewing videos during the initial scoring and coding of data. Any identifiable information, including account names, was removed from the data prior to dissemination. This study

XSL•FO
RenderX

received a Not Human Subjects Research Determination from the Harvard Longwood Campus Institutional Review Board.

Results

Descriptive Analysis of the Content

Our search identified 84 videos posted between February 2022 (the earliest video searching the TikTok hashtag recalled) and October 2023; while data collection was performed in November 2023, no new videos under the hashtag were posted in November 2023. Fifteen videos were determined ineligible for analysis based on non-English language (n=6), country code in the European Union or China (n=1), GAHT not mentioned in the video (n=6), duplicate (n=1), or video post removed following the scrape (n=1). The remaining 69 videos were included in our analysis. The median (IQR) video duration was 56 (23 - 73) seconds. Video characteristics and creator demographics are summarized in Table 2.

[a]GAHT: gender-affirming hormone therapy.

[b]N/A: not applicable.

Common themes that appeared in videos are described in Table 3. Self-identified health care workers created 50% of videos about estrogen and antiandrogen regimens, 46% of videos about GAHT access and legality, and 33% of videos about physical changes on testosterone. They created relatively smaller proportions of videos about testosterone regimens (24%), combating misinformation or social stigma around GAHT (11%), and physical changes due to testosterone (10%). None posted antitrans rhetoric.

Table . Content themes and subthemes appearing in the 69 TikTok videos analyzed.

Content themes and subthemes	n (%), N=69
Physical changes on testosterone	29 (42.0)
Voice changes	20 (29.0)
Facial or body hair growth	11 (15.9)
Clitoral growth	7 (10.1)
Skin changes (acne or oiliness)	6 (8.7)
Body odor changes	3 (4.3)
Body composition changes	6 (8.7)

Emphasizes mental health benefits of access to GAHT	2 (2.9)
Normalizes the use of GAHT	29 (42.0)

[a]GAHT: gender-affirming hormone therapy.

[b]TGD: transgender and gender diverse.

Regarding engagement, videos had a total of 446,318 views, 43,743 likes, 1184 comments, and 438 shares. The sums, medians, and IQRs of engagement measures across each video type are described in Table 4. The top three most viewed videos each discussed physical changes on testosterone therapy and accounted for 46% of total views, 55 of total likes, 32% of total comments, and 56% of total shares. The single most-viewed video (104,800 views) depicted a nurse practitioner discussing

XSL•FO

Quality Rating of the Content

Health education videos averaged 88.3% (SD 11.1%; median 85.7%) on PEMAT-A/V understandability items, and 60.0% (SD 45.8%; median 100%) on actionability items. Together, the weighted mean (SD) PEMAT-A/V score for all items was 81.7% (18.7%). Videos averaged 74.5% (SD 18.4%) in total on the CRAAP test, with mean (SD) component scores as follows: currency, 58.7% (19.2%); relevance, 93.3% (SD 20.0%); authority, 82.7% (SD 35.3%); accuracy, 61.0% (SD +29.3%); and purpose 81.7% (SD 14.1%).

Discussion

Principal Findings and Comparison With Previous Works

This study characterized the creators and content of 69 TikTok videos related to GAHT. The most common videos were those made by TGD content creators who shared personal experiences on GAHT. For example, many videos were part of weekly or monthly series in which the creator reviewed the physical effects of their medications or applied or injected medication on camera while providing updates to their followers. Attitudes among users were overwhelmingly positive, with a few instances of ambivalence or mixed attitudes reflecting a preference for one mode of GAHT administration over another.

The large proportion of personal experience videos, which also had high engagement from viewers, reflects the longstanding popularity of TGD video blogs (vlogs) across other social media sites, including Reddit and YouTube [26-28]. As in the current study, prior work has noted an increased frequency of videos created by testosterone users relative to estrogen/anti-androgen users, which may be partially due to the shorter onset time of visible bodily changes with testosterone use [29,30]. Prior YouTube-based ethnographic research suggests these vlogs simultaneously function as opportunities for creators to reflect on and visualize their own gender affirmation journeys, as well as digital diaries to share their narratives with others and engage in broader dialogue [28]. The prevalence of and engagement with personal experience videos in this dataset suggest that TikTok provides a similar space for TGD GAHT users to continually reaffirm their personal identities and engage with the community through digital narrative-sharing.

Our findings suggest that TikTok also functions as a platform for digital activism and resistance. Nearly a third of videos dealt with issues related to GAHT access, newly imposed restrictions on GAHT use, and disinformation about GAHT in the media. In these videos, creators reviewed the process of obtaining a prescription, described sources of funding, or detailed how users could continue to access GAHT despite restrictive legislation passed in Florida and Utah during the timeframe studied. Many used TikTok's duet function to respond directly to disinformation circulating in the media and among politicians. These videos represent a timely means of intracommunity resistance against restrictive legislation by providing GAHT users with steps to continue GAHT. As legislatures in the United States and abroad attempt to ban and restrict access to care, social media platforms including TikTok may play an increasingly important role in community organizing and harm reduction.

XSL•FO
RenderX

Our results suggest that TikTok provides space for dialogue between GAHT users and health care workers, which may help reduce medical mistrust and facilitate the safe administration of GAHT. Content made by health care workers constituted nearly a quarter of all videos and was created with the intention of sharing health information relevant to GAHT users. These videos showed high levels of engagement, and often directly addressed viewers' comments or private messages. The ability for health care providers to respond directly to GAHT users' questions about hormones supports its potential as a space for effective digital knowledge mobilization, as prior work suggests [2]. Furthermore, health care providers also benefit from this interaction by gaining a deeper understanding of common questions and concerns among TGD people interested in GAHT.

Our analysis of health education videos suggests that information contained in educational videos is of high understandability, low actionability, and moderate reliability. An average PEMAT understandability score of 88.3% across educational videos suggests a high level of accessibility to viewers. The lower average actionability score of 60.0% may reflect the fact that the goal of many health education videos was to explain a particular phenomenon (eg, the mechanisms behind expected physical changes due to testosterone) rather than to guide patients' decisions about treatment.

High scores on the relevance, authority, and purpose components of the CRAAP test (>80%) suggest that educational information regarding GAHT is well-suited to the needs of the intended audience, created by reliable sources, and shared with the purpose of informing viewers about their health. The lower scores on the accuracy and currency components of the scale reflect the finding that while many content creators used their professional experience to support their claims, few cited evidence-based guidelines or provided viewers with further reading or updates as new information emerged. While the content analyzed was overall understandable, it did not reliably contain the level or depth of detail present in evidence-based clinical practice guidelines. It may therefore be important for providers to work with patients to contextualize information about GAHT found on the platform.

Clinical Implications

Our findings have several clinical implications. Providers should be aware that patients may use TikTok as a source of health knowledge, and that this information varies in depth and accuracy. GAHT prescribers may consider incorporating routine screening questions about patients' consumption of medication-related social media content and using these to either augment, contextualize, or correct information found online. As much as GAHT users may use TikTok as a space to seek information from health care providers, it can also better inform providers about TGD patients' needs and priorities. These needs are apparent where videos made by providers and users diverge thematically. For instance, providers created a high proportion of videos surrounding drug safety and monitoring, whereas GAHT users focused more on desired medication effects, suggesting a potential need for comprehensive counseling on expected and adverse effects.

Furthermore, videos created by providers also differed from user-created videos in that few of them directly addressed a nonbinary audience, despite nonbinary content creators being the most well-represented demographic in the videos analyzed, suggesting that there may be a lack of awareness surrounding GAHT-related needs of nonbinary people. In fact, only one health education video created by a provider explicitly addressed a nonbinary audience, and nearly a quarter used language that reinforced a binary gender paradigm (eg, "this video is for anyone transitioning male to female"). Thus, TikTok may also offer cisgender providers an opportunity to better understand the unique needs of diverse groups seeking out GAHT, which may allow for a more patient-centered and culturally responsive approach to counseling.

Limitations

There are several limitations to this study. First, the content analyzed is limited to what appears under the specific search terms #genderaffirminghormonetherapy and #genderaffirming hormones. While there is likely broader discourse on TikTok surrounding this topic, broadening the search terms—for example, to #hormonetherapy or #testosterone—would have yielded results that are not specific or relevant to TGD communities. While the videos analyzed were created over a 20-month period, they represent a single snapshot in time within the rapidly changing landscape of social media.

We were unable to compare quantitative statistics between different video types due to the small sample size for some video types and the non-normal distribution of engagement statistics with videos that were outliers with regard to viewership. Future studies should conduct rigorous statistical comparisons on video metrics in a larger sample size.

Additionally, TikTok has been criticized for its tendency toward "collaborative filtering," a method of predicting users' interests based on their previous views and activity in the app. By using physiognomic data, some argue that TikTok is more likely to recommend creators who look like the platform's white and able-bodied top influencers, and less likely to recommend creators who belong to underrepresented minority groups, which can also be referred to as "shadow banning" [31-33]. In this context, it is important to consider that some perspectives may be systematically privileged over others.

Similarly, the collected data may be vulnerable to bias towards more positive experiences. Users may be more willing to share positive experiences given the nature of the community formed under these hashtags; those with negative experiences may be less willing to share their experiences. However, we attempted to mitigate bias in content selection by using a web scraper rather than a TikTok account for data collection.

Our analysis involved collecting self-reported demographic characteristics from public profiles, which can be falsely reported for a variety of reasons, including stigma or safety concerns. Thus, it is possible that the number of TGD content creators and GAHT users within the dataset was underreported. Moreover, we chose to limit our focus to video content to analyze the dialogue between creators and viewers, though

XSL•FO
RenderX

future research may also include the comment sections of such videos.

Finally, while an abundance of clinical evidence supports the efficacy of GAHT, there remains debate nationally and internationally on certain aspects of GAHT. Videos were rated based on the contemporary understanding of GAHT, with the authorship team comparing information presented in videos to the majority consensus in the academic field; however, we acknowledge that our ratings are limited by a lack of consensus in the clinical community on certain topics related to GAHT.

Conclusions

This study evaluated the discourse around GAHT on TikTok to better understand the extent to which it is being used as a tool for building community and disseminating health knowledge. Overall, our results suggest that TikTok allows GAHT users to document their experiences, connect with other community members, and advocate for GAHT as legislation restricts access to treatment. TikTok also provides a space for direct user-provider dialogue, whereby users can have questions answered by health professionals with a high level of information understandability. Health professionals should be aware that patients may use TikTok as a source of information and should be ready to explore these sources of knowledge with patients, as they vary in terms of currency and quality of supporting evidence. Health care workers may utilize social media platforms such as TikTok as an opportunity for bidirectional learning and health knowledge dissemination between clinicians and GAHT users.

Conflicts of Interest

ASK declares royalties as editor of a McGraw Hill textbook on transgender and gender diverse health care and of an American Psychiatric Association textbook on gender-affirming psychiatric care. The authors declare no competing financial interests.

Abstract

Background: Eosinophilia and hypereosinophilic syndrome (HES) are rare disorders grouped under the term hypereosinophilic disorders. They are diagnosed based on an increased number of eosinophils. They can also cause serious symptoms, including skin, lung, and gastrointestinal problems. These disorders are very rarely recognized due to their rarity and misdiagnosis.

Objective: This study analyzes public interest in hypereosinophilic disorders using data on internet search volume in Germany between 2020 and 2023. Objectives include identifying frequently searched terms, evaluating temporal trends, analyzing seasonal patterns, evaluating geographic differences in search behavior, and identifying unmet information needs and frequently searched risk factors.

Methods: A retrospective analysis using Google Ads Keyword Planner gathered monthly search volume data for 12 German terms related to hypereosinophilic disorders. These terms were selected based on their medical relevance and common usage identified from medical literature. Data were analyzed descriptively, with trends, seasonal variations, and geographical distributions examined. Chi-square tests and correlation analysis assessed statistical significance.

Results: A total of 178 keywords were identified, resulting in a search volume of 1,745,540 queries. The top keyword was “eosophile,” a misspelling, followed by “eosinophilia” and “HES.” The main categories included “Eosinophilia,” “Eosinophils,” and “Churg-Strauss syndrome.” Temporal analysis showed seasonal growth in search volumes, peaking in January 2023, with higher interest during winter. Geographical analysis showed regional variations.

Conclusions: This research shows a growing public interest in eosinophilic diseases, reflected by a steadily increasing search volume over time. This is particularly evident in searches for basic definitions and diagnostic criteria, such as “eosinophils” or “symptoms of eosinophilic diseases.” This increase in search volume, which peaked in January 2023, indicates an increased interest in accurate and readily available information for rare conditions.

KEYWORDS

hypereosinophilia; eosinophilia; public health informatics; web search analysis; rare diseases

Introduction

Background

Hypereosinophilic diseases are defined as the presence of persistently elevated eosinophil counts that can cause tissue damage and inflammation of various organs, including the skin, lungs, or gastrointestinal tract [1,2]. These diseases cause symptoms such as severe itching, breathing problems, and gastrointestinal complaints [1,3-5]. Some severe forms of these diseases are characterized by hypereosinophilic syndrome (HES), in which there is tissue infiltration of eosinophils above accepted thresholds for eosinophilia, which can lead to abnormal damage to organ systems [6-9].

Hypereosinophilic disorders can have a significant impact on the individual, but they are often unrecognized and misdiagnosed, mainly due to their rarity and the heterogeneity of clinical presentation [10-13]. Diagnosis is typically based on the exclusion of other causes of eosinophilia (eg, allergic diseases or parasitic infections) and histopathological and immunohistochemical studies, permitting classification in the following subtypes: myeloproliferative (M-HES), lymphocytic (L-HES), idiopathic (I-HES), and chronic eosinophilic leukemia not otherwise specified (CEL-NOS). [1,10]. Treatment is based

XSL•FO
RenderX

on subtype; corticosteroids plus systemic immunosuppression may be used, as well as cytotoxic agents (hydroxyurea and methotrexate), tyrosine kinase inhibitors (imatinib for M-HES), or targeted biologics (mepolizumab) [4]. Prognosis for HES varies; mortality rates can be as low as 7% to 10% for some subtypes, while mortality rates for CEL-NOS can be as high as 33% over a period of 19 - 90 months [4].

It would be helpful to understand how the public navigates information about hypereosinophilic disorders to identify how this process could be altered to lead to successful diagnosis and treatment [4,14]. Digital technologies have developed to the extent that there is widespread access to online health information [15]. Patients are also more likely to turn to the internet to research their health-related questions, starting with a search for their specific symptoms and continuing with possible underlying causes and treatment plans [16-21]. Therefore, this shift from patients becoming passive recipients of medical advice to active participants in health care has seen a steep increase.

The patient journey—the patient experience from symptom awareness to treatment itself—has become more fluid and individualized [15]. This process may involve many phases, such as seeking signs of symptoms, possible diagnoses, or treatment options. These phases are dependent on individual, emotional, and contextual factors and lead to a series of nonlinear pathways through the health care system. These pathways are particularly convoluted in hypereosinophilic disorders [22] due to changing patient presentations, providers, diagnostic challenges, and lack of public and clinical awareness.

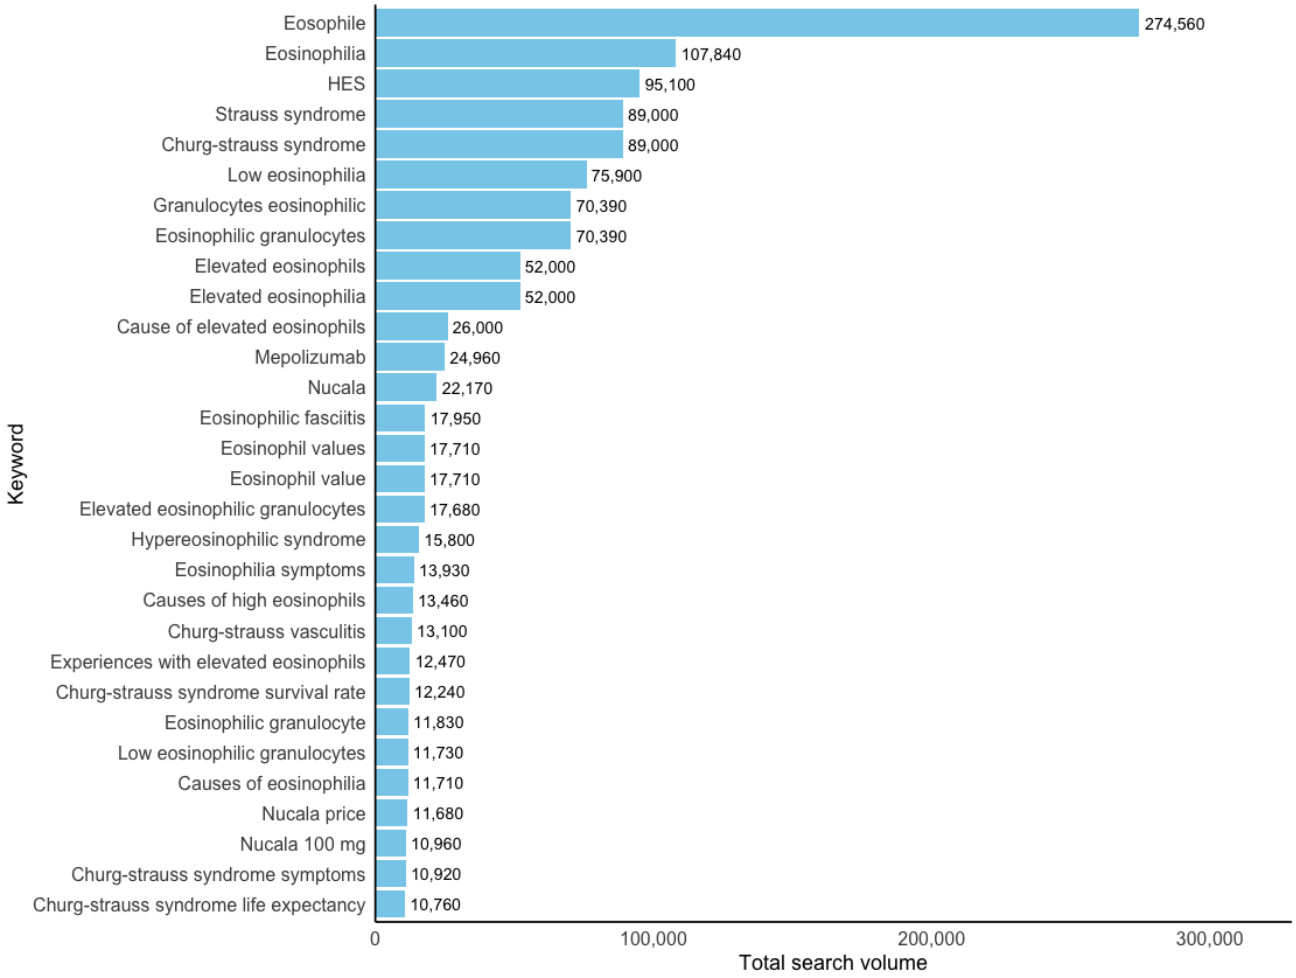
The Google Ads Keyword Planner is a valuable tool that allows users to analyze public interest and engagement with health topics using search volume data [23,24]. This approach allows researchers to monitor real-time data on public interest, identify trends in information tracking, and analyze spatial and temporal variations in interest [25-27]. In contrast, Google Trends provides a broader view of relative interest over time, offering insights into how frequently terms are searched relative to all searches made on Google. While Google Trends normalizes search volume data and provides general trends, it lacks the detailed search volume metrics that Google Ads Keyword Planner offers. Unlike social media, where shared information may be curated and filtered [28], search queries provide a more direct and unfiltered view of individuals' health concerns and information needs. This perspective is particularly relevant for rare and underrecognized conditions such as hypereosinophilic disorders, where traditional sources of public health data may be limited.

Objective

Given the rarity and diagnostic challenges of hypereosinophilic disorders, understanding how the public seeks information about these conditions can provide valuable insights into awareness gaps and unmet informational needs. Therefore, the primary aim of this study is to analyze public interest and information-seeking behavior related to eosinophilic disorders in Germany, using Google search data from 2020 to 2023. By examining trends, seasonal patterns, and geographical variations in search volumes, this study seeks to identify key areas of concern and opportunities to enhance public education on these underrecognized conditions.

Methods

Study Design and Data Collection



In this retrospective analysis, the Google Ads Keyword Planner was used to gather monthly search volume data. Although initially designed for marketing campaigns, this tool effectively provides monthly web search volume data (ie, monthly number of web searches) for research purposes [27,29-31]. To determine the search volume in a specific area, relevant search terms are entered into the planner. The language and geographical settings can then be configured, and the most relevant keywords and phrases for the topic entered.

Search Terms and Keyword Identification

For this study, 12 German search terms related to hypereosinophilia and associated conditions were entered (Figure 1). The goal was to obtain related keywords and phrases and their monthly search volume in Germany between January 2020 and December 2023. The search terms were "Hypereosinophilia," "Hypereosinophilic Syndrome," "Hes," "Eosinophilia," "Blood Eosinophilia," "Reactive Eosinophilia," "Tissue Eosinophilia," "Eosinophilic Granulocytes," "Eosinophilic Syndrome," "FIP1L1," "Mepolizumab," and "Nucala."

XSL•FO
RenderX

Figure 1. Total search volume for the top 30 keywords (2020 - 2023). HES: hypereosinophilic syndrome.

The 178 keywords were reviewed for relevance to hypereosinophilia and grouped inductively into categories based on their association with the disease, clinical subtypes, treatments, diagnostic markers, and related conditions: “Eosinophilia,” “Eosinophils,” “Churg Strauss Syndrome,” “HES,” “Eosinophilic Granulocytes,” “Nucala,” “Mepolizumab,” “Eosinophilic Fasciitis,” “Eosinopenia,” “EGPA (Eosinophilic Granulomatosis with Polyangiitis),” “Eosinophilic Granulomatosis,” “Blood Eosinophilia,” and “FIP1L1.”

Categories for recurring topics were further subdivided into subcategories (eg, diagnostic information). For each keyword, only one subcategory was assigned. The data were analyzed descriptively.

Geographical Scope

The search volume in all of Germany was examined. Search data for all 16 German federal states and cities were analyzed. Cites were selected based on their population and geographic location in order to obtain a representative overview of all of Germany. For a more in-depth view, cities that are of particular interest due to their unique demographics or health-related infrastructure were also included.

The predefined list of cities included in the study comprised cities that are well distributed across the country and include both large and small cities: Bad Bramstedt, Berlin, Bremen, Cologne, Dortmund, Dresden, Erfurt, Frankfurt, Freiburg, Giessen, Hamburg, Hanover, Heidelberg, Jena, Kassel, Kiel, Kirchheim Teck, Leipzig, Magdeburg, Mainz, Mannheim, Munich, Nuremberg, Regensburg, Rostock, and Stuttgart.

Statistical Methods

To summarize and visualize the search volume data, we used descriptive statistics. Means and measures of dispersion (SD and IQR) were calculated for the monthly search volumes in different categories and subcategories. Frequencies and percentages were used to describe the distribution of searches among the identified categories. We applied a time series decomposition to monthly search volume data since January 2020, using the seasonal and trend decomposition using Loess to extract seasonal, trend, and remainder components. This allowed us to quantify seasonal patterns with CIs and to measure the variability in the data.

Temporal and Geographical Analysis

Trends during the study reporting period (January 2020 to December 2023) were assessed using a time series analysis. We applied seasonal decompositions to locate and quantify seasonal fluctuations in search volume (seasonal decomposition of time series). Search queries were processed for each federal state and city, and the search queries per 100,000 inhabitants were calculated to analyze the geographical distribution of the search

XSL•FO
RenderX

volume. This allowed us to identify areas with increased or decreased search activity related to eosinophilic disorders.

Statistical Testing

Chi-square tests were conducted to assess the significance of differences in search volume between categories and regions. This test was useful for determining whether the distribution of searches across categories was statistically different from what would be expected by chance.

Correlation Analysis

Prior to statistical analysis, we tested the normality of the search volume data using the Shapiro-Wilk test. The results indicated a normal distribution (P=.89). A chi-square test was conducted to examine the associations between search volumes and different regions. This analytical strategy helped to explore potential demographic or health-related factors associated with higher search activity. In this map, each tile represents a search term category, and red areas highlight regions with high relative search volume, resulting in an easy-to-understand heat map visualization that makes it simple to see how interest is distributed across regions in the categories. The intensity of the displayed color reflects the number of searches per 100,000 people on average, with light colors indicating minimal search interest and dark colors indicating higher search interest.

Identification of Significant Rises

We calculated z scores for each time point to detect significant increases in search volume. The z score was computed by subtracting the mean search volume and dividing by the SD. Points with z scores greater than 2 were marked as significant rises, indicating substantial deviations from the average trend.

Validation of Methodology

To ensure the validity of the methodology, the search volumes from the Google Ads Keyword Planner were compared with data from Brandwatch (Giles Palmer) [32]. Brandwatch analyzes mentions on various platforms such as Facebook Public, forums, internet-based news, and X (formerly Twitter). This comparison was used to verify whether the identified peaks and trends in search volume can also be found on other platforms and whether similar patterns exist across multiple sources. This ensured that the observed trends are consistent and not distorted by the commercial orientation of Google Ads.

Software and Tools

All statistical analyses were performed using R (version 4.1.2; R Core Team). Spatial data analysis used *rnaturalearth* packages, and visualizations were created with *ggplot2* [33-40].

Ethical Considerations

As the study was based on publicly accessible Google search terms, there was no requirement for institutional review board approval, and informed consent was not applicable.

Results

Overview of Search Volume

Overall, 178 keywords related to hypereosinophilia were identified, resulting in a search volume of 1,745,540 queries from January 2020 to December 2023.

The analysis of search volumes for keywords related to eosinophilic disorders revealed several key insights. Interestingly, the top keyword was “eosophile” with 274,560 searches, despite being a misspelling and lacking medical meaning (Figure 1). This indicates a potential gap in public understanding or a common typographical error. Following this, the correct medical term “eosinophilia” had 107,840 searches, and “HES” had 95,100 searches. Other top keywords with the highest search volumes included “Churg-Strauss syndrome” and “low eosinophilia” (Table 1).

XSL•FO

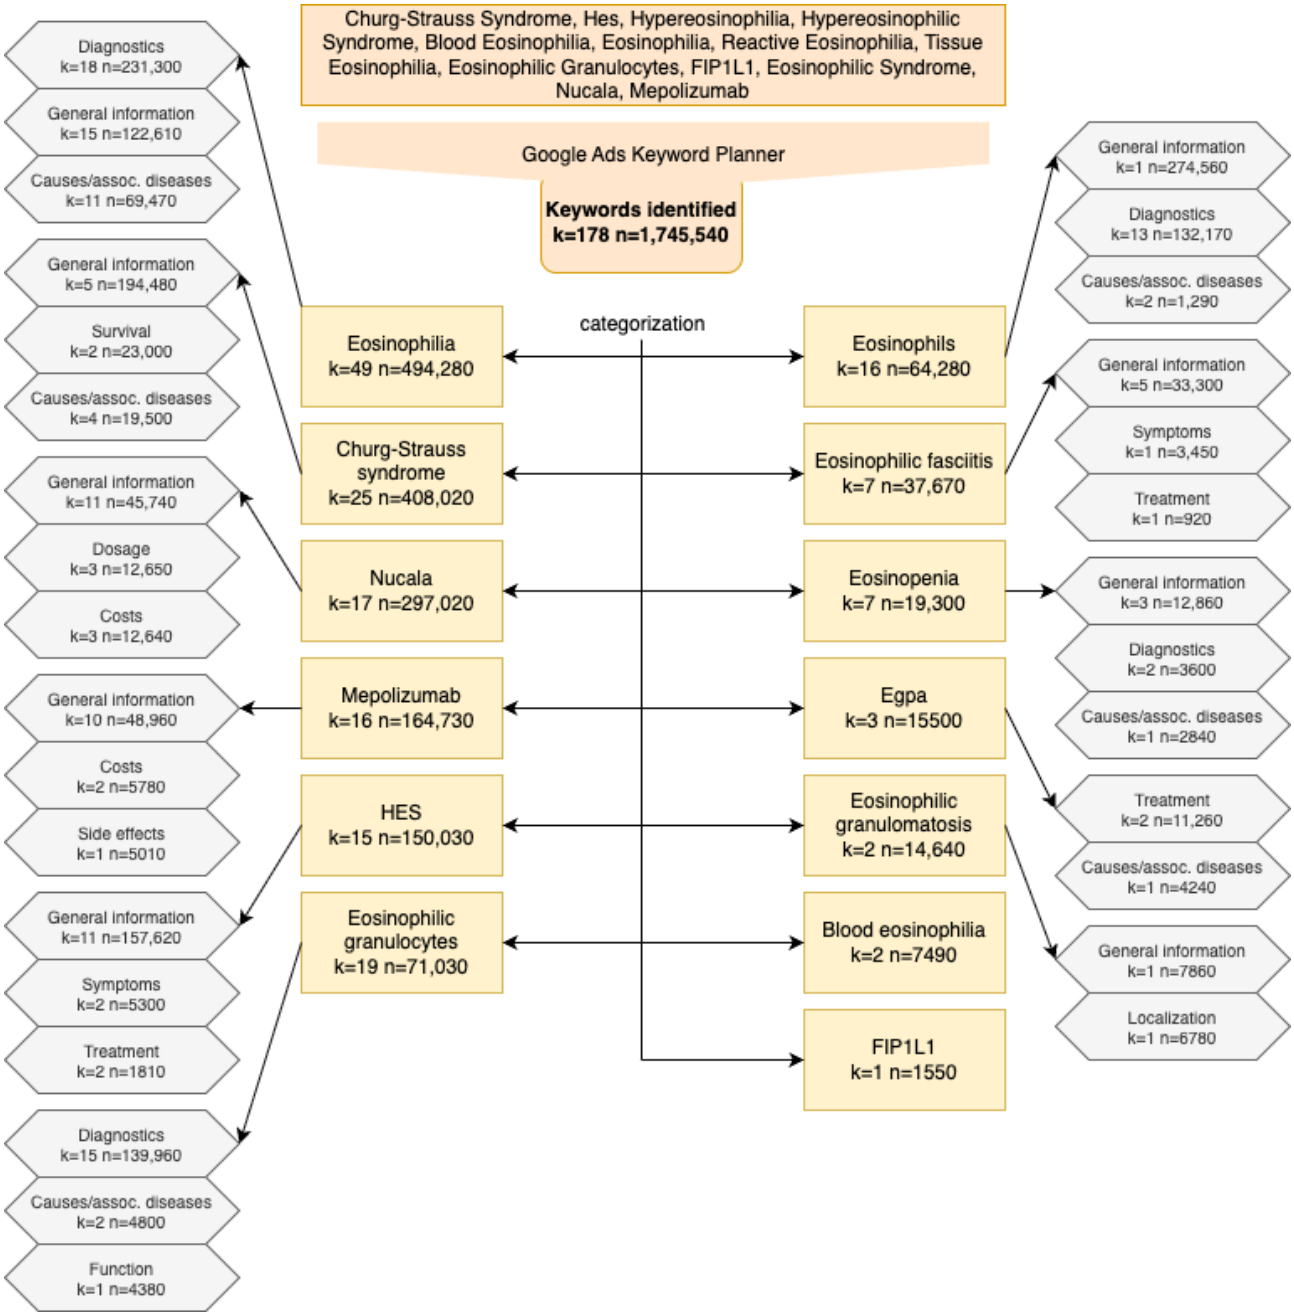
Table . Top 30 unique keywords for each main category and subcategory.

Main category	Subcategory	Frequency of unique keywords, n
Eosinophilia	Diagnosis	18
Eosinophil granulocytes	Diagnosis	15
Eosinophils	Diagnosis	13
Eosinophilia	Causes/associated diseases	11
HES[a]	General information	11
Nucala	General information	11
Mepolizumab	General information	10
Eosinophilia	Symptoms	7
Churg-Strauss syndrome	Treatment	5
Churg-Strauss syndrome	General information	5
Eosinophilic fasciitis	General information	5
Eosinophilia	General information	5
Churg-Strauss syndrome	Causes/associated diseases	4
Eosinophilia	In animals	4
Churg-Strauss syndrome	Diagnosis	3
Churg-Strauss syndrome	Symptoms	3
Eosinopenia	General information	3
Nucala	Dosage	3
Nucala	Costs	3
Blood eosinophilia	General information	2
Churg-Strauss syndrome	Localization	2
Churg-Strauss syndrome	Survival	2
EGPA[b]	Treatment	2
Eosinopenia	Diagnosis	2
Eosinophil granulocytes	Causes/associated diseases	2
Eosinophilia	Treatment	2
Eosinophils	Causes/associated diseases	2
HES	Treatment	2
HES	Symptoms	2

[a]HES: hypereosinophilic syndrome.



[b]EGPA: eosinophilic granulomatosis with polyangiitis.

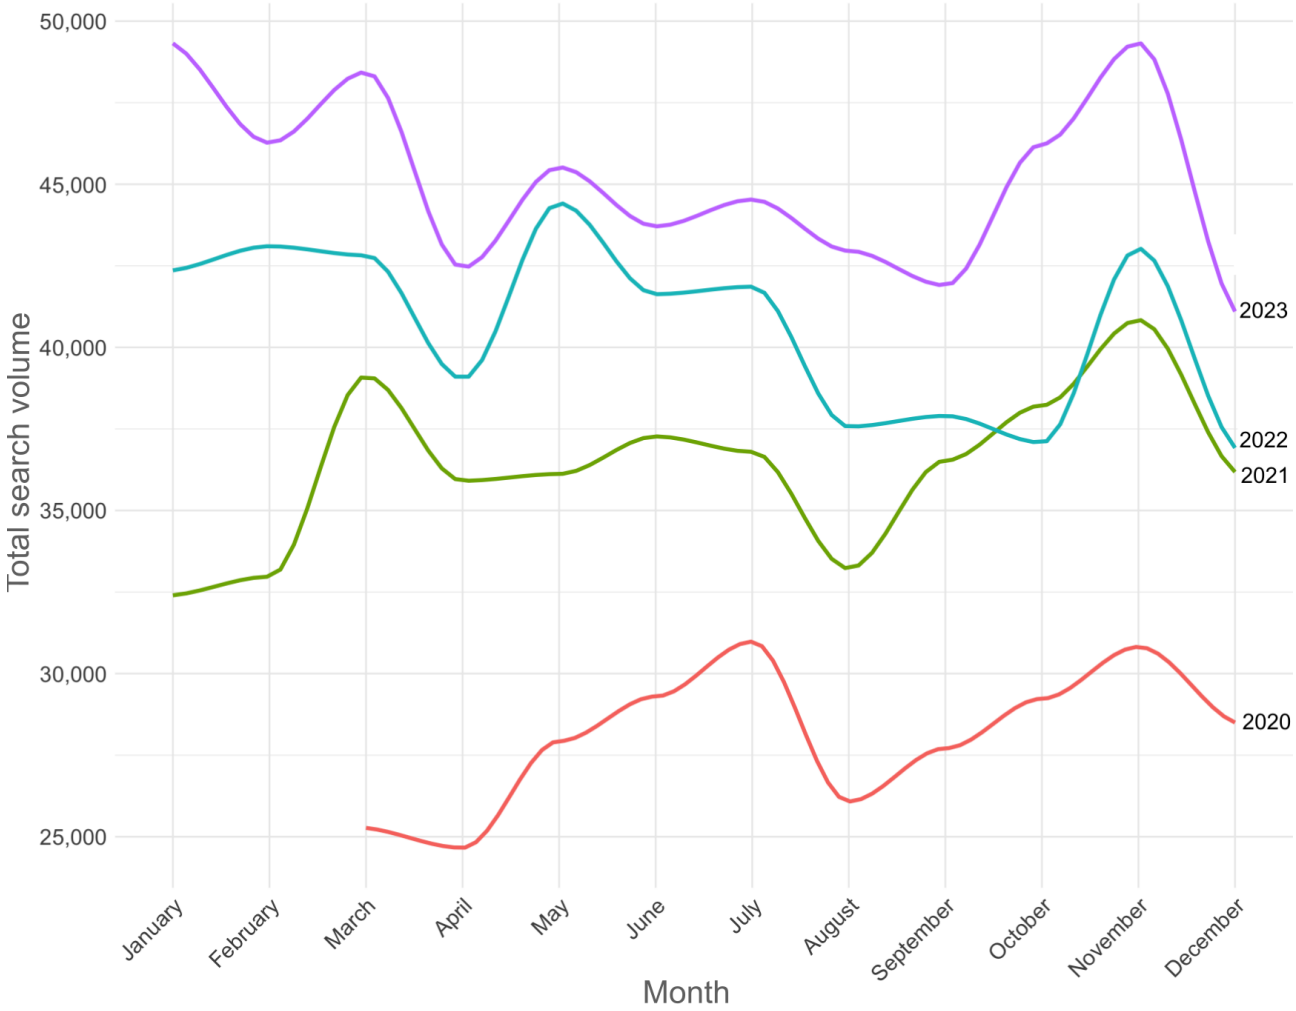
Categorization of Search Terms

These keywords were assigned to the following categories (Figure 2). In terms of main categories, “Eosinophilia” topped the list with a total of 494,280 searches, accounting for 28.32% of the total search volume. This was followed by “Eosinophils” with 408,020 searches (23.38%) and “Churg-Strauss syndrome” with 297,020 searches (17.02%). These categories highlight the primary areas of interest among the public.

XSL•FO
RenderX

Figure 2. Flowchart of data generation and content categorization. This flowchart illustrates the process used to gather and categorize the keywords related to eosinophilic disorders. First, relevant search terms were identified based on their medical significance and prevalence in the literature. Next, data were collected from Google Ads Keyword Planner, which provided monthly search volume information for each term. The identified keywords were then grouped into broad categories such as "Eosinophilia," "HES," "Churg-Strauss Syndrome," and others based on their relevance. Within these categories, further subcategories were created, focusing on specific topics such as diagnosis, symptoms, treatment, and related diseases. For clarity, only the top three subcategories are listed when more than three subcategories exist. HES–related web searches in Germany from 2020 to 2023 were analysed. If no subcategory was created, the group was too small or only general information was searched for. assoc.: associated; EGPA: eosinophilic granulomatosis with polyangiitis; FIP1L1: gene involved in hypereosinophilia; HES: hypereosinophilic syndrome; k: number of keywords; n: number of searches.

Within these main categories, the top subcategories provided further insight into specific areas of interest (Figure 2). For "Eosinophilia," the most searched subcategory was "diagnosis" with 231,300 searches (13.25% of the total search volume), followed by "general information" with 122,610 searches (7.02%), and "causes/associated diseases" with 69,470 searches (3.98%). For "Eosinophils," the leading subcategories were "general information" (274,560 searches, 15.73%), "diagnosis" (132,170 searches, 7.57%), and "causes/associated diseases" (1290 searches, 0.07%). In the "Churg-Strauss syndrome" category, "general information" led with 194,480 searches (11.14%), followed by "survival" with 23,000 searches (1.32%) and "causes/associated diseases" with 19,500 searches (1.12%).



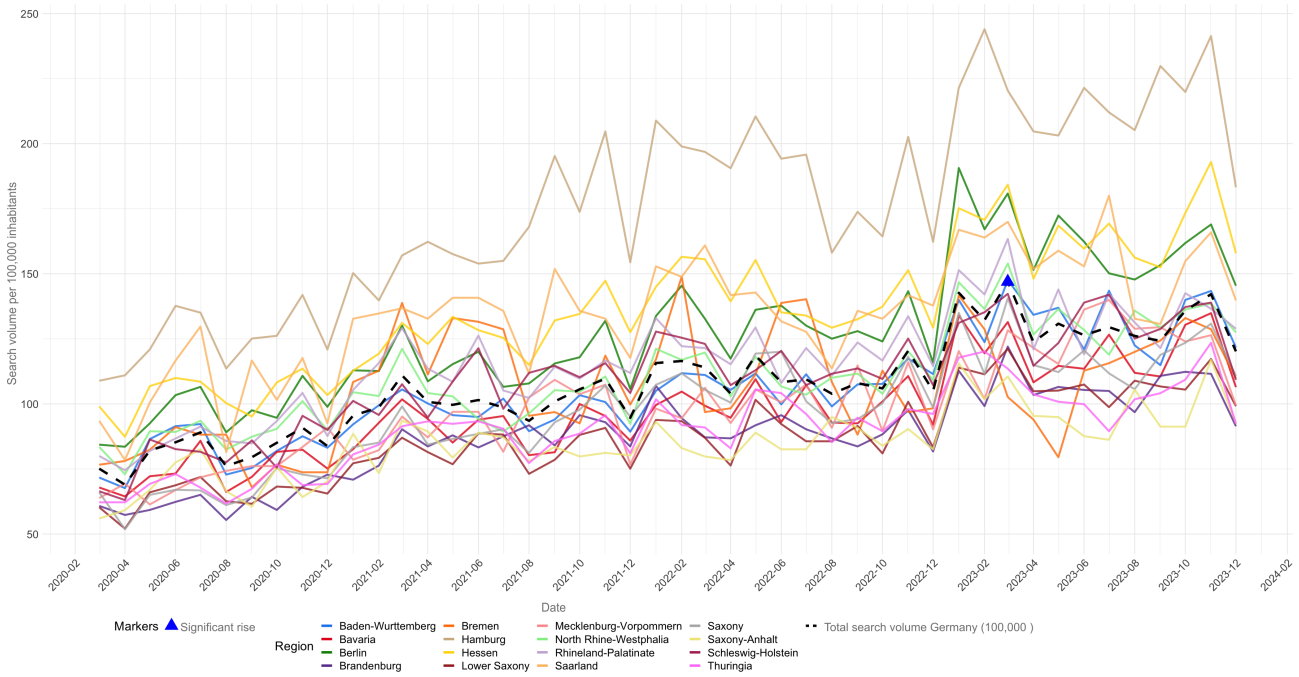
Temporal Trends in Search Volume

From March 2020 to December 2023, eosinophilic disorders exhibited significant growth, peaking in January 2023 at 49,320 queries (Figure 3). Seasonal patterns reveal higher interest during winter months and slight declines in summer, with a consistent yearly increase in overall search volumes. This trend

XSL•FO
RenderX

highlights rising public awareness and interest in eosinophilic disorders over time (see also Figure S3 in Multimedia Appendix 1) .

Figure 3. Total search volume by month over 4 years.



The decomposition of the search volume time series revealed key patterns (Figures S5 and S6 in Multimedia Appendix 1), with Figure S5 in Multimedia Appendix 1 outlining the seasonal and trend decomposition using Loess breakdown into seasonal, trend, and remainder components, and Figure S6 in Multimedia Appendix 1 confirming the seasonal estimates' reliability through diagnostic plots and CIs. The seasonal component showed periodic fluctuations, with notable peaks and troughs, such as a peak in March 2020 (2889) and a low in December 2020 (–4165). This indicates regular cyclical variations in search volume. The trend component exhibited a consistent upward trajectory, increasing from 24,925 in March 2020 to 46,654 by December 2023, suggesting sustained growth in search interest. The remainder component displayed random fluctuations, reflecting irregular variations not explained by the seasonal or trend components. CIs for the seasonal component showed variability, particularly in March 2020, with intervals ranging from –1687 to 7467. Over time, these intervals became narrower, indicating more precise seasonal estimates.

Geographic Distribution

From March 2020 to December 2023, the total search volume per 100,000 inhabitants in Germany showed notable variations (Figure 4 and Figure S1 in Multimedia Appendix 1). Nationally, the peak search volume was 147 per 100,000 inhabitants in March 2023, and the lowest was 69 in April 2020. At the state level, Hamburg recorded the highest peak of 244 searches per 100,000 inhabitants in February 2023. In contrast, Saxony-Anhalt's peak was 117 in November 2023. Seasonal patterns were observed, with increased search volumes across most regions at the start and end of the year. The lowest volumes generally occurred in April 2020 across various states, reflecting consistent national trends.

XSL•FO
RenderX

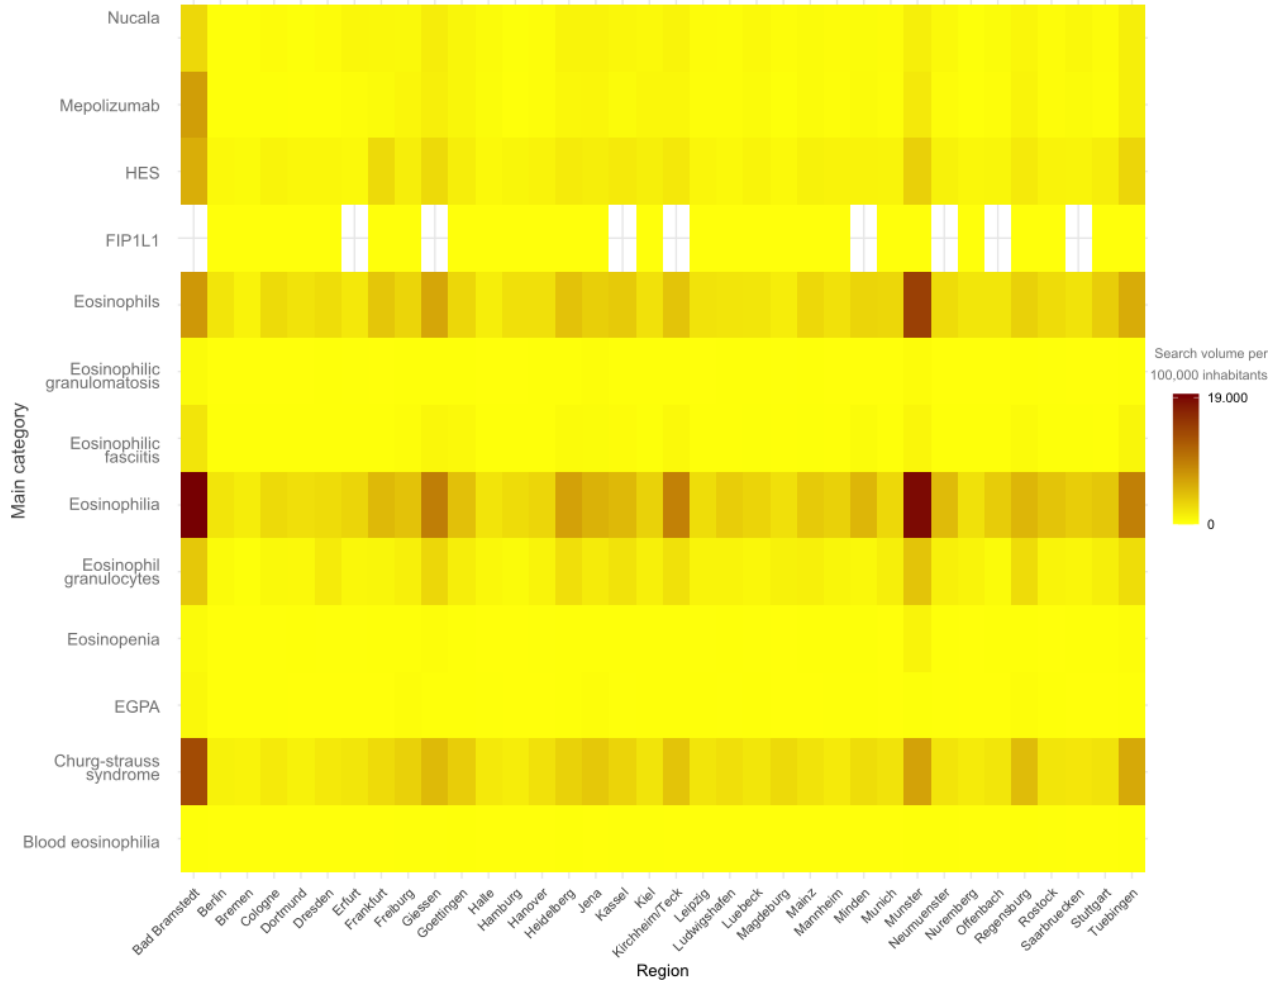


Figure 4. Total search volume over time per 100,000 inhabitants for Germany and by state.

The heatmap (Figure 5 and Figure S4 in Multimedia Appendix 1)) illustrates the search volumes per 100,000 inhabitants across the different German cities. “Eosinophilia” exhibits the highest search volume in Bad Bramstedt with 19,523, while Bremen shows the lowest with 1513. Similarly, for “Churg-Strauss syndrome,” Bad Bramstedt has the highest value at 13,562, compared with Bremen’s 1043. For medications such as “Mepolizumab” and “Nucala,” the highest values are also in Bad Bramstedt (7004 and 2832, respectively), with Bremen having the lowest (207 and 218, respectively). Other cities such as Munster and Tuebingen also display high search volumes, particularly for “eosinophils” (14,529 in Munster) and “Churg-Strauss syndrome” (6154 in Tuebingen).

XSL•FO
RenderX

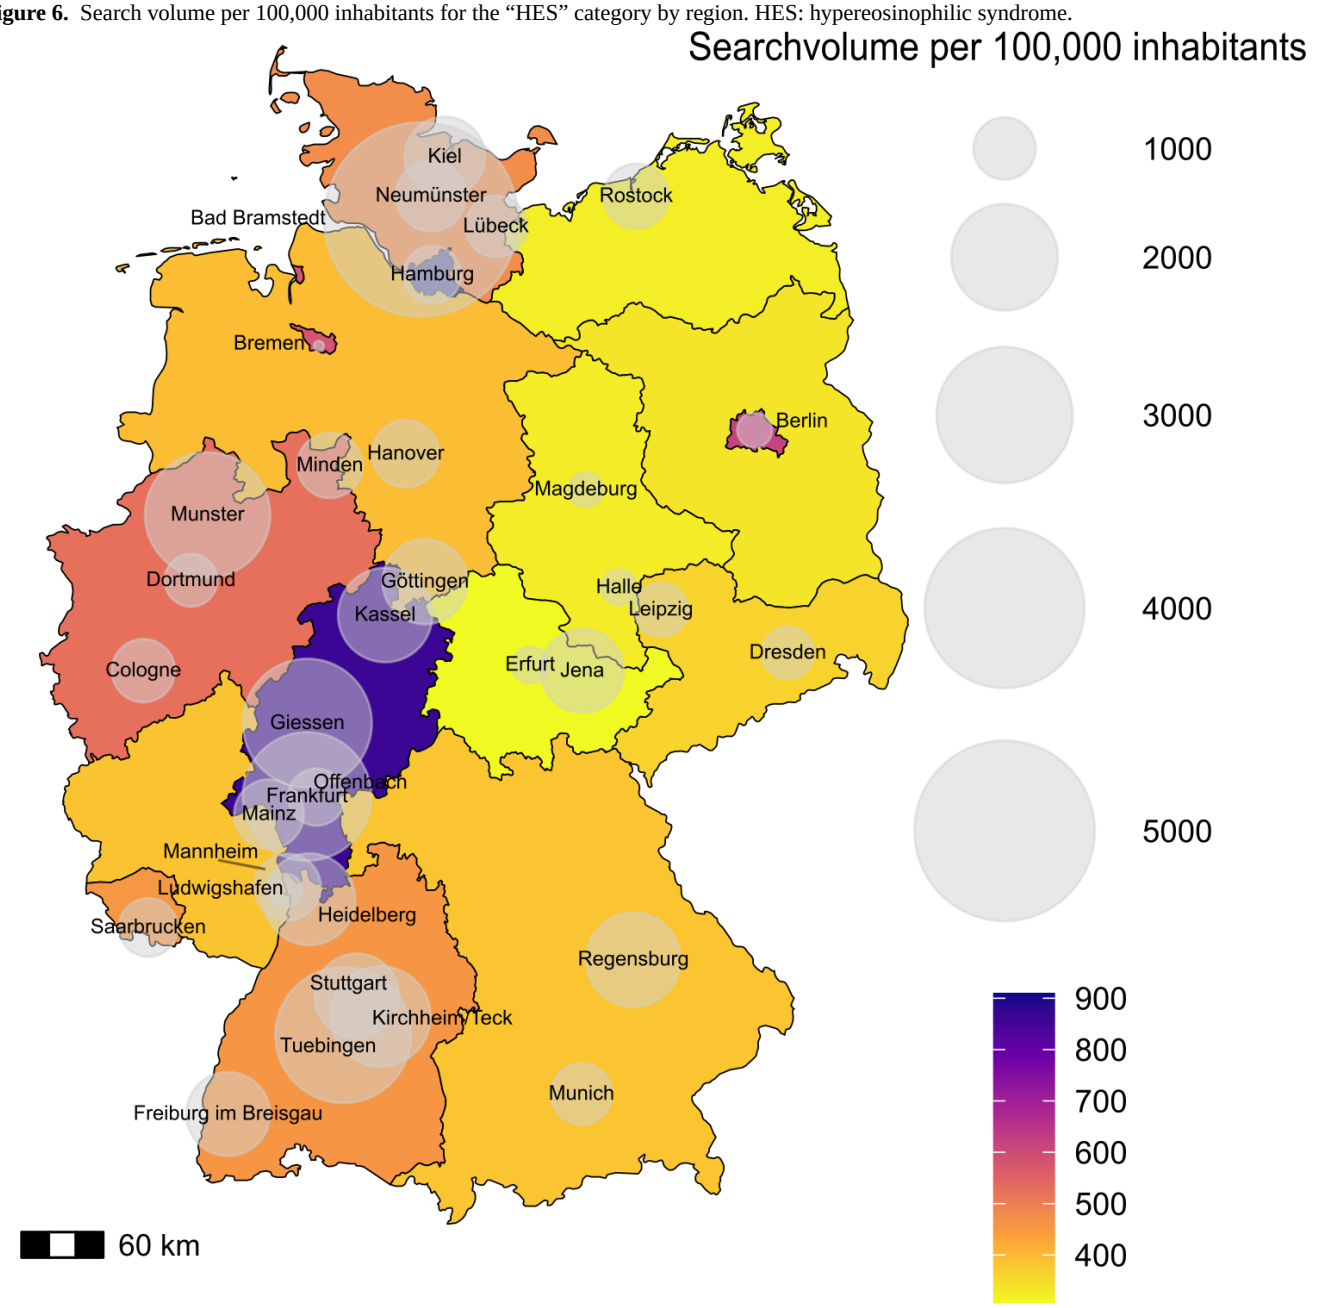

Figure 5. Search volume per 100,000 inhabitants for key categories across regions in Germany from 2020 to 2023. EGPA: eosinophilic granulomatosis with polyangiitis; FIP1L1: gene involved in hypereosinophilia; HES: hypereosinophilic syndrome.

The analysis of the geographical distribution of the total 4-year search volume for the category “HES” per 100,000 inhabitants only shows remarkable differences across different regions and cities (Figure 6). Hamburg has the highest search volume at 854, followed by Hessen with 805. Thuringia, Saxony-Anhalt, and Mecklenburg-Vorpommern have the lowest volumes at 304, 318, and 327 per 100,000 inhabitants, respectively. Among cities, Bad Bramstedt has the highest search volume at 5738 per 100,000 inhabitants. Tübingen, Giessen, and Frankfurt follow with 2989, 2736, and 2719 respectively. Münster reports 2600 searches, Kirchheim Teck reports 1825, Kassel reports 1666, and Regensburg reports 1665. Heidelberg, Göttingen, Stuttgart, and Freiburg im Breisgau show volumes of 1598, 1441, 1433, and 1413, respectively. The lowest search volumes are in Erfurt, Halle, Berlin, and Magdeburg with 690, 683, 680, and 676, respectively, and Bremen has 587 searches per 100,000 inhabitants.

RenderX

Figure 6. Search volume per 100,000 inhabitants for the "HES" category by region. HES: hypereosinophilic syndrome.

Validation of Search Volume Trends With External Data Sources

To validate the findings from Google Ads Keyword Planner, we compared them with data from a platform [32] that analyzes mentions across social media, forums, internet-based news, and X (formerly Twitter) (Figure S2 in Multimedia Appendix 1). The data revealed notable peaks in January 2023, particularly in internet-based news, and a peak in October 2022 for forum mentions. These trends aligned with the spikes observed in the Google Ads search volume data, supporting the hypothesis that the increases in search activity are reflected in broader public discussions, indicating genuine rises in interest about hypereosinophilic disorders."

Correlation Analysis

The chi-square test result was highly significant (P<.001), indicating a strong association between the categories of search terms and the regions after normalization per 100,000 inhabitants. This suggests that the frequency and type of searches for HES–related information are significantly influenced by regional factors (Table S1 in Multimedia Appendix 1).

Identification of Significant Rises

Significant rises in search volume are marked with blue triangles in Figure 4. These were detected using z scores, indicating periods where the search volume increased substantially beyond typical variations. Notably, in March 2023, there was a significant rise in search volume, reaching 147 per 100,000 inhabitants, well above the average with a z score of 2.08. This points to a notable event or increased interest during this period, potentially indicating a surge in public concern or awareness about the topics searched.

Discussion

Principal Findings

From March 2020 to December 2023, a total of 1,745,540 search queries on eosinophilic diseases were documented, suggesting a high level of public interest in eosinophilic diseases in Germany. The increasing number of searches conducted, particularly during the winter months, may indicate a growing public interest in rare diseases, possibly due to external influences (eg, seasonal worsening of symptoms and increased media coverage) or displacement effects on search engine suggestion lists. It is striking how often people enter search terms incorrectly, such as “eosophile,” which accounted for 274,560 search queries, suggesting gaps in the public’s understanding of medical terminology. The frequent misspelling of terms indicates a barrier to finding correct medical information. These spelling mistakes show that there are gaps in the public’s knowledge of medical terms, which also points to the need for digital literacy campaigns. Raising awareness and educating the public about the correct terminology can help improve the search for information and support self-education, especially with regard to rare diseases.

Regional differences in search volume suggest that cities like Hamburg, Bad Bramstedt, and Freiburg show higher engagement, likely due to the presence of specialized health centers and greater access to medical information. In comparison, Saxony-Anhalt and Bremen show a lower search volume because there are fewer specialists in these regions and consequently less awareness of the disease. These rates may vary depending on disease prevalence and regional health campaigns, as indicated by the peak in January 2023. Future studies should investigate how access to health care, disease prevalence, and regional campaigns may impact public interest in rare diseases. Interestingly, the most common subcategory for searches related to the broader topic of eosinophilia was diagnosis, suggesting a desire among the public to learn more about the identification and symptoms of eosinophilic disorders. This suggests that those searching for such terms may not yet have been diagnosed and are looking for possible causes of their symptoms. The spike to 49,320 searches in January 2023 may be the result of public health campaigns or media coverage and illustrates how external events influence public health information behavior.

Insights into user preferences highlight some important issues related to eosinophilic diseases, particularly in the area of diagnosis. Conversely, public health efforts should focus on simplified and accessible materials for patients in the early stages, containing credible knowledge about symptoms and evaluations to support efficient and correct diagnosis. Searching and geographically examining keywords can enable targeted public health campaigns in unconscious areas, which can shorten the diagnostic delay and lead to earlier detection and better outcomes. Seasonal peaks in search volume, particularly during the winter months, may reflect worsening of respiratory symptoms due to the colder weather [41]. Due to the exacerbation of eosinophilic diseases, including HES, during this period, people feel the need for more information [41]. The peaks can also be explained by increased public health campaigns or media attention, as respiratory problems tend to receive more attention during the flu season [42].

Regions with lower engagement, such as Saxony-Anhalt and Bremen, may benefit from targeted outreach strategies to increase awareness and education about eosinophilic disorders. Health campaigns in these areas could focus on improving access to information, addressing gaps in public knowledge, and raising awareness about available specialized care centers [43-46]. Additionally, digital platforms, including social media and search engines, can be leveraged to disseminate accurate and timely information, directly reaching individuals in these regions who may not have access to traditional sources of health education. Such approaches could help reduce diagnostic delays by guiding individuals to seek appropriate care sooner and more effectively [43].

To validate the findings, data from social media and internet-based news were examined. The trends, especially the peaks in January 2023 and October 2022, align with search volume spikes. However, social media data may reflect specific user groups rather than the broader population, and news data can be influenced by external factors such as public health campaigns. While these sources provide useful insights, they should be interpreted cautiously as they may not fully capture the overall public interest in eosinophilic disorders.

Comparison With Literature

The findings of our study are consistent with previous research on rare diseases, which highlights the significant challenges faced by patients in obtaining a timely and accurate diagnosis. Hypereosinophilic disorders present with complex clinical features that can lead to diagnostic delays and misdiagnoses, similar to other rare conditions. The 2013 report on the impact of rare diseases shows that patients with rare diseases often have to undergo long diagnostic pathways. In the United States, it takes an average of 7.6 years, and in the United Kingdom, 5.6 years before a correct diagnosis is made [44]. During this period, patients typically consult up to 8 physicians and receive 2-3 misdiagnoses, with 82% of social media comments on HES reporting diagnostic delays, highlighting the complexity of diagnosing rare eosinophil-driven disorders [45].

In our study, the diagnosis-related subcategory was the most frequently searched, reflecting the public’s struggle to find accurate information and the challenges associated with diagnosing hypereosinophilic disorders [46,47]. This pattern of information-seeking behavior suggests a significant unmet need for awareness and educational resources, both for the public and health care professionals [48].

This finding aligns with previous research on atopic dermatitis and pollen allergies, which also indicated that online search data could reveal significant gaps in public knowledge and help identify areas requiring targeted health education [26,29,49-51].

Strengths and Limitations

A key strength of this study is its use of Google Ads Keyword Planner, providing real-time search data to assess public interest in eosinophilic disorders. This approach demonstrates the

XSL•FO
RenderX

potential of infodemiology for rare disease research, offering insights into awareness, informational needs, and regional variations, which traditional data sources often lack. Compared with studies such as Pauer et al [52], which used search queries for rare disease epidemiology, our study focuses specifically on eosinophilic disorders, adding nuance to public engagement analysis [53,54]. Additionally, unlike Pauer et al [52] and Tozzi et al [55], which examined information quality and user demographics, we provide real-time trends in public interest, enhancing the understanding of disease awareness.

Several limitations should be considered when interpreting these findings. Google Ads Keyword Planner, while effective for data collection, is primarily a marketing tool and may introduce biases or limitations in data accuracy for research purposes [56,57]. The high search volume for misspelled terms such as “eosophile” may have skewed the results and points to gaps in public education that were not fully explored in this study. Future research could investigate the reasons behind common misspellings and their impact on information retrieval and understanding. Furthermore, the generalizability of the results may be limited by demographic and access biases. Younger people are generally more tech-savvy and therefore more likely than older cohorts to search for health information on Google, skewing the search data toward their demographic group. This study did not account for differences in internet use by age, socioeconomic status, and region, and the results may not generalize to different segments of the population [58]. The final limitation concerns the temporal relevance of the data, which extend to December 2023 but may not account for newer trends or developments, such as newer treatment options or educational campaigns, that could influence interest and search behavior outside the time frame of this study.

Conclusion

The findings of this study provide valuable insights into public interest and information-seeking behaviors related to hypereosinophilic disorders in Germany. The data suggest that there is a growing awareness and concern about these rare conditions, as evidenced by the increasing search volumes over time. The pronounced regional differences highlight the need for localized health education and resource allocation to address potential disparities in awareness and access to information.

Our results emphasize the urgent need for faster, more accurate diagnostic pathways and enhanced awareness among health care professionals to improve the management and outcomes for patients with rare diseases such as HES and EGPA. The study underscores the potential of using Google search trends as a tool for public health surveillance, particularly for rare and underrecognized conditions such as hypereosinophilic disorders. Future research should aim to integrate demographic data and explore the impact of public health campaigns and health care access on search behaviors. Additionally, efforts should be made to improve public understanding of these disorders through accurate and accessible information, potentially leveraging the very platforms where information-seeking is occurring. Addressing these knowledge gaps could lead to better patient outcomes through earlier diagnosis and more informed health decision-making.

Acknowledgments

Parts of this study were funded by an unrestricted research grant from GSK GmbH and Co KG.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

MH was responsible for conceptualization, methodology, investigation, formal analysis, and writing the original draft. SS contributed to conceptualization, methodology, and writing, as well as review and editing. AZ also contributed to conceptualization, methodology, and writing, as well as review and editing.

Conflicts of Interest

MH once received a personal honorarium from GSK, AZ received personal honoraria from GSK, and SS has no conflict of interest.

Multimedia Appendix 1

A correlation matrix of search volume data for various keywords related to eosinophilic disorders across 27 cities in Germany. This matrix highlights the relationships between different terms such as "eosinophilia," "Churg-Strauss syndrome," "HES," and related treatments and conditions. The data reflect regional variations with notable differences in search volume across cities. These correlations provide insights into public interest in specific aspects of eosinophilic disorders and help identify patterns in search behaviors linked to geographic location.

Abstract

Background: Antimicrobial resistance (AMR) is a major global health issue heavily influenced by human behavior. Effective communication and awareness-raising are crucial in curbing AMR, with social network sites (SNSs) significantly shaping health behaviors. Despite their potential, current analyses of AMR on SNSs have focused mainly on top-down communication initiatives.

Objective: This study aims to examine AMR on Instagram (Meta Platforms), identifying key actors, content themes, and the nature of the communication to understand how AMR is portrayed and perceived.

Methods: Based on the sender-message-channel-receiver model, this study used content analysis to review publicly accessible posts on Instagram. The data refer to 24 months, focusing on the hashtag "#antibioticresistance." After cleaning the data, 610 posts (10% of the total 6105) were analyzed.

Results: Content creators were predominantly information drivers or professionals in science and health. Posts frequently featured text-dominated visuals or images of bacteria and laboratory tests. However, the AMR posts were found to be siloed, with limited engagement beyond specific interest groups. The study highlighted the neutrality and accuracy of the content but noted the challenge of reaching a broader audience.

Conclusions: While Instagram serves as a platform for accurate and informative AMR communication, the post of it remains confined to niche groups, limiting its broader impact. To enhance engagement, AMR discussions should be integrated into more general interest content, use visually compelling formats, and encourage institutional participation and interactive user engagement.

antimicrobial resistance; social media engagement; communication; Instagram; health communication; content analysis

Introduction

Background

Antimicrobial resistance (AMR) is a major global issue, causing substantial health burdens and societal costs. Every year, about 1.3 million people die from infections caused by antimicrobial-resistant bacteria, and this figure is predicted to increase to 10 million by 2050 [1,2].

The Role of Community Awareness in Combating AMR

Community knowledge and awareness raising are key factors in curbing resistance because AMR largely depends on human behavior [3-5]. In addition to medical use, which is the primary driver of AMR [6,7], there is plenty of individually and contextually induced health and lifestyle behavior impacting human health—but also animal health and the environment—such as food production and consumption [8], international travel [9], or the adoption of basic hygiene practices to avoid infection spread [10]. Previous research stresses the necessity of considering the contextual motivations and preferences of participants and that health communication needs to explore and engage with these [11,12]. The World Health Organization's (WHO's) Global Action Plan highlights the need to emphasize and improve AMR awareness and understanding through effective communication, education, and training [13].

The Influence of Social Network Sites on Health Behaviors

Social influences shape health and lifestyle behaviors to a high degree. Research has highlighted the influence exerted by social network sites (SNSs), which stand as structural determinants of health nowadays for their role in information exchange and diffusion of beliefs [14]. SNSs are web-based services that allow individuals to (1) construct a public or semipublic profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system [15]. SNSs are frequently used to address and communicate health issues [16]. They were used in a few intervention studies to raise awareness of AMR, for educational purposes, and to promote behavioral change [17-21]. International health bodies such as the WHO and the European Centre for Disease Prevention and Control also engage in SNSs—primarily during Antimicrobial Awareness Weeks—and promote their use in awareness-raising campaigns [22,23]. However, to date, the analysis of AMR on SNSs has been almost completely limited to top-down communication, with a primary focus on X (formerly Twitter) [24-26]. Recent studies have highlighted the effectiveness of SNSs in rapidly disseminating health-related evidence to professionals, particularly during public health emergencies, where timeliness and platform dynamics influence uptake and visibility [27]. At the same time, SNSs demonstrated considerable potential for reaching broader audiences with public health messages, influencing awareness, attitudes, and behaviors [28]. However, the very features that facilitate wide dissemination can also contribute to the amplification of misinformation. A systematic review found that a significant proportion of health content on popular SNSs is inaccurate or misleading, especially in emotionally charged or polarizing contexts [29]. A recent bibliometric study showed a sharp rise in research on how SNSs spread health misinformation during the COVID-19 pandemic, underlining the need for active monitoring and strategies to reduce harm [30]. Content analyses of platforms such as YouTube have also revealed large amounts of misleading health information, such as false claims about vitamin D as a treatment for COVID-19, highlighting the difficulties in ensuring reliable health communication online [31]. This dual potential underscores the importance of developing communication strategies that not only ensure the visibility of accurate and accessible information but also address the risks associated with misinformation, particularly in the context of AMR, where public understanding and behavior are crucial. It has been shown that institutional awareness events, such as the World Antimicrobial Resistance Awareness Week (WAAW)—the major global initiative dedicated to raising awareness and promoting action on AMR—can rapidly increase the number of posts, including among laypeople, although this increase tends to be short-lived, typically returning to baseline levels within 48 hours [25]. Another study focusing on Twitter looked into the types of influential users and showed that the discussion was primarily influenced by news sources, health professionals, and governmental health organizations [24]. A study analyzing the information shared by Instagram (Meta Platforms) users of oral and topical antibiotics for treating acne vulgaris claimed the potential use of the SNS in elucidating patients' behavior and attitudes [32].

Among SNSs, Instagram is a platform in steady growth [33], among the most popular in size (fourth SNS globally, with 1478 million active users in 2022) [34] and impact on users' decision-making [35]. Content-wise, Instagram is a favorite SNS for social purposes [36]; therefore, it holds the potential for spreading knowledge and raising awareness of AMR, or on the contrary, to contribute to misinformation. Furthermore, considering that Instagram is an image-based platform of the first choice for entertainment purposes and co-creating with brands via social media [36], where topics such as food, wellness, and travel are amongst the most typical, the influence on health and lifestyle behavior of relevance for AMR is also worth attention.

To explore how Instagram content may shape awareness and behaviors related to AMR, it is useful to apply a theoretical model that captures the dynamics of message dissemination and reception.

Understanding Berlo's Sender-Message-Channel-Receiver Communication Model

The sender-message-channel-receiver (SMCR) communication model, developed by Berlo in 1960 [37,38], outlines 4 essential components in the communication process: the sender, the message, the channel, and the receiver. This model has been extensively used in communication research, including as a framework for understanding how SNS users disseminate and receive information [39-41].

The sender refers to the originator of the communication, whose characteristics, such as communication skills, knowledge, and attitudes, influence the effectiveness of the message delivered. In SNS contexts, the sender is any individual or organization posting content, with their social status or credibility impacting how their message is perceived.

The message itself consists of the information being transmitted. It can take various forms, including text, images, or videos, depending on the channel used.

The channel is the medium through which the message is transmitted, such as visual or auditory platforms. On Instagram, which serves as the primary communication channel in this context, users interact primarily through visual and textual content. In addition, online communities can also be considered vehicles or channels for displaying information. Typically, hashtags are not only part of the message but have a broad spectrum of functionality, including being a powerful tool for marketing promotion of products and services, acting as an evaluation marker that can set the interpretation model of the message, and activating networks of associations [42]. Finally, the receiver is the target audience of the message, whose characteristics—such as attitudes, social background, and previous knowledge—play a crucial role in determining how the message is interpreted.

RenderX

Studying AMR Communication on Instagram

This study aims to examine the communication about AMR on Instagram, identifying key actors, content themes, and the nature of the communication to understand how AMR is portrayed and perceived using Berlo's SMCR communication model. Thus, the study contributes to addressing a broader challenge: while AMR is recognized as a pressing global health threat, little is known about how it circulates on SNSs like Instagram or how effectively these messages engage the general public. By analyzing how messages are framed, who produces them, and which publics they appear to reach, this study offers insights that can inform the development of more inclusive and effective digital communication strategies in the AMR field.

Methods

Study Design

This research uses a descriptive design and is grounded in inductive reasoning. The method of data collection and analysis is content analysis, which, in this study, integrates both quantitative and qualitative approaches [43,44]. The study incorporates quantitative elements but is primarily qualitative, guiding the choice to pursue trustworthiness as a measure of quality [45,46]. To foster transferability, a detailed description of the Methods and Results is offered. The study was planned following Bengtsson's recommendations to enhance the credibility of content analysis [47]. In the planning phase, the scope, relevance, and breadth of the aim, the size and characteristics of the sample and unit of analysis, the choice of data collection method, the choice of analysis method, and the ethical implications were thoroughly considered.

Data Collection

The data refers to the 24 months between December 1, 2020, and November 30, 2022. The timeframe was selected to include twice the WAAW, taking place in November. The feed posts (reels and stories were not considered) were collected retrospectively using an automated scripting tool for web scraping [48]. It was decided to use "#antibioticresistance" in the search, a widely used and recommended hashtag to engage in conversations about AMR [49], because it was deemed as a simpler but still scientifically proper expression of the notion, to which the public is relatively more used with respect to alternatives such as "antimicrobial resistance" or "AMR" [50].

The search returned 7380 hits. After cleaning the data, there were 6105 posts. Posts were excluded according to the following criteria: when non-English languages dominated the posts, duplicates, and reposts. To ensure the representativeness of the sample, hence enhancing the credibility and transferability of the study, a 10% sample ratio was applied (N=610). To prevent over-reporting content generated in concomitance with special AMR-related events, stratified random sampling was applied. For each month, 10% of the posts were randomly selected. The sample size was determined by the presumption that the data were sufficient based on the pretesting training sessions and pilot-testing results (78 posts) and consistency with previous sample sizes of Instagram studies [51,52]. This was later confirmed during the analysis by confidence in having reached, or closely approached, data saturation [53].

Data Analysis

Since there was no codebook of AMR in general on SNSs, it was created based on previous analyses of AMR in SNSs and a scoping review of AMR communication. The creation of the codebook was based on the SMCR model, and the coding process was adapted from Cohen et al [52]. To enhance credibility and dependability, investigator triangulation measures were implemented. A stepwise approach alternating individual and team sessions was used to enhance intercoder consistency and reliability [54]. As a pretest, 4 coders independently analyzed 15 different posts each in training sessions, followed by an iterative process of consensus coding and updating the original codebook. In a successive pilot coding round, the 4 coders analyzed together a random sample of 18 posts in order to confirm consistency in categorization. The results of the pilot test were included in the final sample. Afterwards, each coder independently analyzed one-quarter of the posts. Each coder's analysis was double-checked by another coder with full visibility of the original coding, and discrepancies were discussed and harmonized.

Content analysis was used in the study [55,56]. The unit of analysis comprised the caption, image, hashtags, and the content creator—their profiles were observed to categorize them according to their declared interests and visibility. Throughout the analysis, coders went back and forth between the post and the categories to enhance intracoder reliability and minimize the risk of misinterpretation [54]. During the coding process, posts were evaluated on the language used in captions, the emotional connotations of the images, and the context provided by hashtags. To assess the tone of the Instagram posts related to AMR, each post was categorized based on predefined sentiment categories: neutral, emotive, or promotional. For instance, posts categorized as emotive often included language that invoked fear or urgency about AMR, while neutral posts presented factual information without emotional framing. In the codebook, the application of the SMCR model generated 5 overarching categories, which are described together with the subcategories in Textbox 1. The categories in Textbox 1 were established through a rigorous content analysis of Instagram posts containing the hashtag "#antibioticresistance." Each category reflects a distinct type of content creator, based on their users' descriptions, bios, and linked websites. The professional background, communication style, and intended audience contributed to the categorization also. By categorizing content creators and their communication styles, this taxonomy provides valuable insights into the landscape of AMR discourse on Instagram, revealing both the strengths and limitations of current engagement strategies.

XSL•FO
RenderX

Textbox 1. Description of the categories and subcategories.

Sender: Content creator

Based on users' descriptions, bios, and linked websites. The content of the post contributes to the categorization, too. The number of followers and "likes" per post was noted.

- Ecology and animal care: Users who connected antibiotic resistance (AR) to animal rights and animal care.
- Science and health: Users working in biomedicine, biotechnology, and medicine who connected AR to science and health.
- Information driver: Users who focus on spreading knowledge and raising awareness of AR.
- Naturopathist: Users who promote a holistic approach to wellness, often focused on lifestyle and diet.
- Pharmacy and veterinary: Users who connected AR to the pharmacy and veterinary fields.
- Education: Education institutions and students.
- Motivators and art: Wellness motivators and illustrators posting on AR.

Receiver: Audience

Inferred from the post content (image, caption, and hashtags) and considering the presumable interest of the content creator, that is, when the post creator caters or not specifically to their closest audience.

- General audience: The content does not appeal to any specific audience.
- Customers: The post, implicitly or explicitly, aims to sell products or services.
- Followers: The content is directed to the creator's Instagram followers.
- Peers: The post is primarily directed to the creator's peers, for example, vegan community and health care professionals.
- Patients: The post seeks to communicate with patients.
- Students: The post seeks to communicate with students.
- Local community: The post is directed to a local community.
- Health organizations: The post is directed toward health care organizations and policymakers.

Message: Purpose

- The manifest primary reason for which the post is made.
- Information and awareness: Spreading knowledge and raising awareness of AR.
- Advertising: Selling products or services.
- Propaganda: Promoting ideological or political points of view through biased or partial communication.
- Infotainment: Sharing humorous, relatable content, often through comics or illustrations to inform about AR.

Message: Tone

The gist or attitude of the post, including the image, caption, and hashtags.

- Neutral: A communication style tendentially tends to be information- and fact-based.
- Emotive: A communication style involving emotional content or potentially triggering an emotional response
- Promotional: A style involving marketing-style communication strategies

Message and channel: Centrality of AMR

An appraisal of AR importance within the post (image, caption, and hashtags).

- Main: AR is the most important subject in the post.
- Relevant: AR is an important subject in the post.
- Collateral: AR is a subject of secondary importance in the post.
- Irrelevant: The post is about something else, unrelated to AR (AR only appears in the hashtags).

In addition, other descriptive characteristics of the posts were noted: (1) the number of followers of the creator of the posts (sender); (2) the image content and type (message): text (the visual section of the post, whether static or a carousel, is dominated by words), visual object (the visual section of the post, whether static or a carousel, is dominated by a visual object, eg, images, pictures, photos, graphics, and illustrations),

XSL•FO
RenderX

video, or audio; (3) the hashtags (channel); (4) the number of "likes" obtained by the posts (receiver).

Ethical Considerations

This study analyzed publicly accessible Instagram posts tagged with "#antibioticresistance" using a custom web scraping script that accessed content viewable without login, mimicking human browsing behavior. The tool did not access private or password-protected data. While platform terms of service do not always clearly address noncommercial academic research, the study acknowledged the complex and evolving legal and ethical landscape of automated data collection [57]. No personally identifiable information was collected, stored, or quoted. Usernames, profile information, and other potentially identifying content were excluded to minimize the risk of reidentification. The posts included a mix of location-specific and nonlocation-specific content, and we did not systematically categorize them based on geographic references. The analysis focused on aggregated patterns in publicly shared communication, not on individual users.

Although ethical review was not required for the use of public data, the study followed established ethical guidance for social media research, including transparency in reporting, minimization of harm, and attention to user expectations of privacy [58,59]. The overall aim was to contribute to the understanding of public health communication, not to evaluate or profile individuals.

Results

The results show that the sender categories could be divided into 7 main content creator types, with the biggest group being the information driver (n=186), followed by the professionals (n=147). Table 1 details the content creator types and general characteristics of their posts. The most common hashtags used are "bacteria," "AMR," "antimicrobialresistance," "antibiotic," "medicine," and "health." Typically, images contained text messages or pictures and illustrations—often of bacteria and test samples. The captions often described how antibiotic resistance (AR) and antimicrobial resistance (AMR) spread, why it needs to be stopped, and connected health consequences.

[a]The top hashtags refer to the most frequent hashtags used per content creator category.

[b]The top image content refers to the most frequent pictures and illustrations used per content creator category.

[c]The total number of "likes" and "Followers"refers to the content creator categories, not to individual Instagram users.

[d]The average number of "likes" and "Followers"refers to the content creator categories, not to individual Instagram users.

[e]AMR: antimicrobial resistance.

In the following, each sender category (eg, "Ecology and animal care") and their different sender subgroups (eg, "Vegans and vegetarians") are described. For each sender category, the most relevant channel feature, namely the hashtags, and message features, such as characteristic visual content, are described. Accounting for the receiver, the number of "likes" is reported. For each sender subgroup, the emphasized message features include purpose, image content, tone, and centrality of AR. At the same time, as for the receiver analysis, the type of audience for which the post was made is shown.

Ecology and Animal Care

These users connected AR to environmental and animal rights issues. The average number of "likes" per post (n=28) is relatively low in this sender category (see Table 1). Their top hashtags were "vegan," "plantbased," "antibiotics," "deforestation," and "factoryfarming." Pictures often showed animals such as cows, fish, and birds and food products. The category was divided into 3 subgroups: "Vegans and vegetarians," "Farming and food companies," and "Others in food and diet."

"Vegans and vegetarians" informed and promoted diet change and animal welfare to a great extent. The tone was emotive for most posts (56%, 18/32 participants) and, sometimes, they slipped into propaganda. Almost half of the posts (44%, 14/32 participants) have AR as a centrality in the post. Animal welfare was also crucial to the next subgroup—"Farming and food companies." They encouraged eating organic and focused on showing good animal care and food production. Relatively often (14%, 3/21 participants) their posts served commercial purposes and were directed to their customers. Foremost, 10 out of 21

XSL•FO
RenderX

participants (48%) adopted a neutral tone in their posts, where AR was relevant but not the main focus of the post. These 2 subgroups are those with the highest number of posts where the centrality of AR was deemed only collateral (24%, 5/21 participants). In the "Others in food and diet" subgroup, organizations and individuals that share a focus on food and diet without falling into any other subgroups were grouped. Further details are shown in Table 2.

Table . Ecology and animal care subgroups' characteristics.

Subgroup	Purpose, n (%)				Audience, n (%)			Image content, n (%)			Tone, n (%)			Centrality of AR[a], n (%)			
	I&A[b]	Propaganda	Advertising	Infotainment	General	Peers	Customers	Text	Visual object	Video or audio	Emotive	Neutral	Promotional	Main	Relevant	Irrelevant	Collateral
Vegans and vegetarians (n=32)	25 (78)	4 (12.5)	3 (9.4)	0 (0)	28 (87.5)	4 (12.5)	0 (0)	18 (56.3)	11 (34.3)	3 (9.4)	18 (56)	10 (31)	4 (13)	14 (44)	7 (22)	6 (18)	5 (16)

[a]AR: antibiotic resistance.

[b]I&A: information and awareness.

Science and Health

These sender categories showed their work within the AR field, either in research or care. Table 1 shows that the average number of "likes" per post (n=173) and users' followers (n=22,552) was the highest among all main categories. The category is divided into 4 subgroups: "Biomedicine labs," "Healthcare staff," "Researchers," and "Healthcare facilities." Their top hashtags were "bacteria," "AMR," "microbiology," "science," and "antibiotic." Pictures typically showed pills, laboratory tests, bacteria, and health care personnel.

"Biomedicine labs" encompasses collective profiles of laboratories and individuals creating laboratory-life content, thus focusing on scientific-specific aspects, such as AR mechanisms. This subgroup engages the most with its peers. The "Healthcare staff" subgroup consists of health care professionals. Their posts focused on proper antibiotic use and the threat posed by AR. Their audience was the public and, occasionally, a specific class of patients and their peers in health care. The "Researchers" subgroup comprises users who do research in academic or private settings. For the most part, they work in biomedicine and biotechnology. However, with respect to the "Biomedicine labs" subgroup, they focused more on individual work and achievements and, overall, gave a more personalized perspective to their posts and tried to reach a broader audience. The last subgroup, "Healthcare facilities," involves hospitals, clinics, ambulatories, etc, often providing private services. Their user profiles are mainly collective or of individual users communicating on behalf of or about the health care facility. Their communication was similar to that of the "Healthcare staff" subgroup but tended to engage local communities and promote their services more. Further details are shown in Table 3.

[a]AR: antibiotic resistance.

[b]I&A: information andawareness.

Information Driver

This main sender category of Instagram users is information-driven, and their manifest purpose is to spread knowledge and awareness. Their communication is effective, sometimes even entertaining, as humor is not disdained, and their content is tendentially short and easily accessible. As seen in Table 1, their top hashtags include "AMR," "antimicrobialresistance," "superbugs," "health," and "antibiotic." Pictures depicted pills and health care personnel. They have a comparatively high engagement from their audience in terms of number of "likes" (156 on average per post). This category has 3 subgroups: "AMR organizations and communities," "Journalists and reporters," and "Companies."

"AMR organizations and communities" involves nongovernmental organizations, communities, networks, and others focused on AMR. They mostly share information regarding AMR and AMR-related events (eg, the World AMR Awareness Week and conferences). This subgroup has the highest percentage of AMR-centered posts (84%, 66/79 participants), yet 14 out of 32 posts had a neutral tone (70%). The "Journalists and reporters" subgroup encompasses science news-based profiles, a few journals and newspapers or magazines, but also individual journalists and reporters. Usually, they reported recent scientific research results for the general audience but also for students and their followers and promoted AMR awareness and events. This subgroup tended more than others to use text in the image space of the posts (55 out of 77 participants). The last subgroup is "Companies." They primarily used the platform to promote their products (eg, tests, drugs, and supplements) but delivered their communication in terms of AMR information and awareness spreading. They often targeted potential customers and health organizations. This subgroup tended more than others to use pictures in the image space of the posts (25 out of 30 posts). Further details are shown in Table 4.

[c]AMR: antimicrobial resistance.

Naturopathist

These users promote a holistic approach to wellness, often focused on lifestyle and diet. An active lifestyle, keeping a balanced gut microbiota through wise food choices, and avoiding unnecessary antibiotic use were hot topics. The most common hashtags were "antibiotics," "health," "antimicrobialresistance," "bacteria," and "infection." Pictures were often associated with food or health. This sender category includes the subgroups: "Natural healers," "Body and nutrition," and "Environment and health" subgroups.

Specific to the "Natural healers" was the latent message that the individual users were personally engaged in AMR. Relatively often, the posts were used to promote their products (eg, probiotics and natural antimicrobials) or services (eg, mindfulness and homeopathy consultancies). The second subgroup, "Body and nutrition," included fitness enthusiasts who share information and tips about healthy eating. The "Environment and healthcare" subgroup involves individuals focusing on the environment, health, and sustainability. The latter two subgroups' tone was coded as the most emotive with 3 out of 5 and 2 out of 4 posts being emotive. The last group's communication was even characterized by anger. Further details are shown in Table 5.

[a]AR: antibiotic resistance.

[b]I&A: information and awareness.

Pharmacy and Veterinary

Users in this sender category focus on spreading knowledge about correct antibiotic use and AR and promoting their products and services for human and animal health. More than other categories, they include "One Health" in their posts. Their top hashtags involve "antibiotics," "antimicrobialresistance," "pharmacy," "antibiotic," and "antibioticstewardship," and the pictures primarily concern pills, bacteria, and hands (see Table 1).

The subgroups are "Pharmacists and vets"—pharmacy and veterinary medicine professionals—and "Pharmacy and veterinary companies." The latter subgroup has the highest promotional tone with 4 out of 15 of the posts (27%). Further details are shown in Table 6.

Table . Pharmacy and veterinary subgroups' characteristics.

Subgroups	Purpose			Audience				Image content			Tone			Centrality of AR[a]			
	I&A[b]	Infotainment	Advertising	General	Peers	Customers	Health organization	Text	Visual object	Video or audio	Neutral	Emotive	Promotion	Main	Relevant	Irrelevant	Collateral

Education

This sender category top hashtags were “antibiotics,” “bacteria,” “medicine,” “microbiology,” and “AMR.” Their top images comprehended research highlights, infographics, research findings, and laboratory tests. The category encompasses “Students” and “Education institutes.” The subgroup “Students” includes upper secondary education students, undergraduates, and graduate students (PhD students were placed in the Science and Health category).

Users in the “Students” subgroup shared what they learned about AR and promoted proper antibiotic use. Also, users in “Education institutes” created posts to spread awareness, besides promoting their courses and activities and highlighting research findings. It is the category whose posts were coded as using the most neutral tone (91%, 21/23 posts). Further details are shown in Table 7.

Table . Education subgroups’ characteristics.

Subgroups	Purpose			Audience			Image content		Centrality of AR[a]			
	I&A[b]	Infotainment	Advertising	General	Peers	Students	Visual object	Text	Main	Irrelevant	Relevant	Collateral
Students (n=21)	19 (90.5)	2 (9.5)	0 (0)	17 (80.9)	4 (19)	0 (0)	16 (76.2)	5 (23.8)	15 (71)	3 (14)	2 (10)	1 (5)

[a]AR: antibiotic resistance.

[b]I&A: information and awareness.

Motivators and Art

This sender category’s top hashtags were “antibiotics,” “microbiology,” “bacteria,” “antibiotic,” and “research.” Their top pictures included artwork, bacteria, and selfies (see Table 1). The category involves users who are less focused on AMR. Its subgroups are “Motivators” and “Art.” The former involves users who try to influence and provide feed content of interest, including AR. The latter involves illustrators and art communities that have created content for AR.

The “Motivators” subgroup often resorted to personal narratives, connected AR to life experiences, and promoted healthy habits. The “Art” subgroup used relatively more pictures in the image space of the posts, and 4 out of 13 (31%) used an emotive (sad or scary) tone. Further details are shown in Table 8.

Table . Motivators and art subgroups’ characteristics.

Subgroups	Purpose				Audience		Image content			Tone			Centrality of AR[a]			
	I&A[b]	Infotainment	Advertising	Propaganda	General	Followers	Visual object	Text	Video or audio	Neutral	Emotive	Promotion	Main	Relevant	Irrelevant	Collateral

[b]I&A: information and awareness.

Discussion

Principal Findings

The main findings of this study reveal that while Instagram serves as a platform for disseminating accurate and informative content about AMR, the discussions are largely confined to niche groups, limiting broader audience engagement. The findings showed a heterogeneous and siloed user landscape, where top-down communication is delivered by those who are knowledgeable or have a linked purpose, often of a commercial nature with minimal interaction beyond specific interest communities, suggesting a need for more inclusive and visually compelling content to enhance public awareness and engagement on this critical health issue. These results confirm previous studies [24-26].

Senders and Receivers

Although users created posts that were accessible to a general audience, the broader public rarely engaged with the content or showed visible interest. Virtually no content was created by someone not already engaged in the AMR field or not promoting specific viewpoints, services, or goods. The fragmented and siloed landscape of AMR on Instagram is also confirmed in the

XSL•FO
RenderX

analysis of user engagement patterns, which reveals that "likes" of posts and interactions occur predominantly within specific user groups, with each subgroup gravitating towards content tailored to their interests and priorities. This is shown in the images, the way posts are formulated and that most "likes" derive from other users within the same main category. For instance, a post by a "Science and health" user related to AMR and infection prevention would gain higher engagement rates among users in the same category and individuals with a vested interest in public health issues. In a nutshell, AMR is of no interest to the Average Joe of Instagram. Only a few posts had health organizations among their recipients and very few health authorities and policymakers, highlighting the platform's limitations as a forum for broader policy discussion. The challenge of informational homophily and its siloing effect for which science and health content reach almost exclusively already engaged audiences has been long known, and it was also detected in this study, indicating challenges in overcoming audience segmentation on SNSs [60,61]. It is also possible that algorithmic filtering limits the visibility of AMR content to users outside niche communities. Since content exposure is shaped by previous behavior and engagement patterns, users who are not already interacting with health-related content may be less likely to encounter posts about AMR, even if they might find the topic relevant or engaging [62].

The major actors in the AMR discussion on Instagram are the "Science and health" and "Information driver" content creators. These 2 groups are highly engaged in the AMR field, either possessing extensive professional expertise or being well-informed on the subject. Both groups want to raise awareness, but they do it either by practicing stewardship AMR (Science and health) or mobilizing individual and societal actions (Information drivers). They, together with "Pharmacy and veterinary" and "Education" users, have a specific responsibility deriving from being (and being perceived as) specialists and experts to communicate about AMR in a truthful, nonbiased, and educated manner, as whenever they engage in health and science communication through SNSs, there is the potential for impacting public health and individual behavior and public trust in general [63,64]. These senders are perceived as experts, and their social status as professionals or well-informed individuals lends authority to their messages. This aligns with the SMCR model, where the sender's characteristics—like their knowledge and credibility—determine the effectiveness of communication.

Messages

The purpose of 3% of the posts (18/611) was coded as propaganda, meaning that the content promoted ideological or political points of view through biased or partial communication. For the majority, this type of communication was adopted by users who stressed their concern for animal health and the environmental consequences of AMR. Therefore, AMR and antibiotic use are not ideologically or politically invested in themselves, at least not yet. Such communication happened in conjunction with animal and environmental themes, which tend instead to be polarizing, especially in social media, which are designed to monetize on disagreement among users [65].

Overall, the content of the posts was accurate and conveyed in a neutral tone. Narratives and images aimed at triggering an emotional response were also used but without compromising the veracity of the content, thus to be considered, for the most part, as a way to attract an audience and motivate behavior change through the mediating role of self-relevant emotions (primarily fear) [66]. Noteworthily, almost no content highlighted the role and responsibilities of institutions about AMR.

Posts were text-dominated to an extent above average for Instagram users. This was predictable, considering that they aimed at spreading information and raising awareness about AMR. A 2020 study on the Centers for Disease Control and Prevention's Instagram posts showed similar results about the role of text in the visual section of the analyzed posts [67]. A recent research study by Charani et al [68] on the message content produced by key actors in global health about the visual depiction of AMR found that the current narrative is one of power imbalances, where women and children from low-income and middle-income countries are presented with less dignity, respect, and power than those from high-income countries. On a positive note, none of this was detected in this study. Therefore, the problem of degradingly representing AMR stands with international health bodies but is not shared by other Instagram content creators, not even in the posts whose purpose was deemed as propaganda or that adopted an emotive tone. Charani et al [68] has also shown that imagery in global health communication plays a crucial role not just in transmitting facts but in shaping public understanding, emotional responses, and awareness of infectious diseases, including AMR. Their analysis of visual practices across global health documents highlights how images, when ethically and contextually used, can embed health issues in the public imagination and evoke empathy [68]. In our study, many Instagram posts featured images such as stylized bacteria, pills, or laboratory scenes. However, these visuals were often used in an illustrative or aesthetic way, with limited contextual or emotional framing. Given Instagram's visual-first design, future AMR communication on the platform could benefit from adopting more purposeful and ethically grounded imagery to broaden public engagement and improve risk communication.

Channels

In this study, hashtags are considered as channels, serving multiple functions beyond grouping content. Hashtags, in this context, were also a vehicle for marketing, activism, and community engagement, allowing senders to align their messages with specific networks of associations and broadening the scope and impact of their communication. Different sender categories used hashtags strategically based on their intended message and audience. For example, users in the "Ecology and animal care" category used hashtags like "vegan," "plantbased," and "deforestation" to align AR with environmental and animal rights issues. Here, hashtags extended the message beyond health care, invoking broader themes that resonate with specific "green" values and networks. Similarly, users in the "Science and health" category frequently used hashtags such as "bacteria," "AMR," and "microbiology," which are directly related to scientific work and communication. These hashtags helped cater

XSL•FO
RenderX

scientific content to targeted peers within the scientific community, as well as an informed public. Hashtags also served a commercial function, particularly in the "Pharmacy and veterinary" and "Information driver" categories. Hashtags like "pharmacy," "antibioticstewardship," and "health" not only connected the posts to public health but were also marketing tools for promoting products and services, often with a neutral tone to maintain credibility.

Rauschnabel et al [69] identified 10 different motivations for using hashtags (in order of frequency): amusing, organizing, designing, conforming, trendgaging, bonding, inspiring, reaching, summarizing, and endorsing. This research mainly showed organizing and reaching use, namely, to structure and organize the content of posting and to meet the conventions of specific groups of interest, respectively. To a minor extent, also conforming to use, that is, showing the desire to meet the conventions of specific groups of interest was observed.

Limitations

The study findings should be interpreted considering several methodological choices. A key strength lies in the use of stratified random sampling based on time, which ensured a balanced representation of content across the 24-month period while maintaining analytic feasibility. A 10% sample was drawn (N=610), consistent with established practices in media and communication research where full-population analysis is often impractical [70]. While this enabled the identification of dominant patterns and themes, rare or emerging discourses may have been underrepresented. Temporal stratification helped mitigate this by capturing variation in posting behavior over time [71]. To enhance credibility and dependability, coding was conducted iteratively, including pilot testing, coder training, and cross-checking. These strategies, along with attention to data saturation, supported the trustworthiness of findings. The study focused exclusively on Instagram and the hashtag "#antibioticresistance." While this defined a clear and relevant dataset, AMR-related discussions may also occur under other hashtags or on other SNSs such as X or Facebook. Platform-specific user bases and engagement formats may influence how AMR is communicated and perceived. Future studies should broaden the scope to include additional platforms and terms. Automated accounts were not identified or excluded in this study. Since bots can inflate engagement metrics, future work should consider detection methods to ensure accurate interpretations of user interaction.

Finally, while the SMCR model provided a useful structure, it does not fully capture the participatory, multimodal nature of SNSs. Future work may benefit from combining it with frameworks better suited to networked communication.

Conclusions

The findings of this study provide an overview of how AMR is communicated on Instagram, particularly through the lens of the hashtag "#antibioticresistance." It is evident that while Instagram serves as a platform for disseminating valuable information about AMR, the engagement with this content is largely confined to niche communities rather than reaching a broader audience. This conclusion synthesizes the key findings, discusses the implications for public health communication, and suggests pathways for enhancing engagement and awareness around AMR on social media platforms.

The content analysis of 611 Instagram posts revealed several critical insights into the landscape of AMR communication. First and foremost, the primary intention behind these posts was to inform the public about AMR, with 497 out of 611 of the posts (81.3%) categorized as information-driven. The predominant content creators were classified as "Information drivers" and "Science and health" professionals, who are engaged in raising awareness about AMR. Their posts were characterized by a neutral tone, with a significant amount of text-based content aimed at educating the audience about the implications of antibiotic resistance.

Despite the accuracy and neutrality of the content being commendable, the study highlighted a concerning trend of the isolated nature of the conversations of AMR within specific interest groups. The majority of engagement, as indicated by the number of likes and interactions, occurred within these niche communities, suggesting that the broader Instagram audience, or average individuals, remains largely disengaged from AMR discourse. This finding aligns with existing research that emphasizes the challenges of reaching diverse audiences in health communication, particularly in the context of social media.

The implications of these findings for public health communication are significant. AMR represents a pressing global health crisis, and effective communication strategies are essential for raising awareness and fostering behavioral change among the general population. Given the reliance on social media as a primary source of information for many individuals, particularly younger demographics, it is critical that AMR discussions are made more accessible and engaging. The findings of this study highlight the need for more inclusive, relatable, and visually engaging content that can resonate with a broader audience. To address the challenges identified in this study and promote communication that is actionable and impactful for diverse audiences, the following recommendations are proposed: (1) integrate AMR discussions into more general interest posts, such as stories related to daily life, popular culture, and trending topics in order to attract the attention of nonexperts; (2) use more visually engaging content that cuts through the noise; (3) increase institutional engagement; (4) promote inclusive narratives; (5) improve engagement strategies and campaigns that require user participation, such as challenges, question-and-answer sessions, and live discussions, to boost engagement and interaction or series of educational posts; and (6) highlight the individual and collective responsibility for AMR. Ultimately, addressing the challenges of siloing and promoting a more inclusive dialogue will be essential in mobilizing collective action against this critical global health issue.

Abstract

Background: Social media platforms are increasingly used for both sharing and seeking health-related information online. TikTok has become one of the most widely used social networking platforms. One health-related topic trending on TikTok recently is attention-deficit/hyperactivity disorder (ADHD). However, the accuracy of health-related information on TikTok remains a significant concern. Misleading information about ADHD on TikTok can increase stigmatization and lead to false "self-diagnosis," pathologizing of normal behavior, and overuse of care.

Objective: This study aims to investigate the quality and usefulness of popular TikTok videos about ADHD and to explore how this content is perceived by the viewers based on an in-depth analysis of the video comments.

Methods: We scraped data from the 125 most liked ADHD-related TikTok videos uploaded between July 2021 and November 2023 using a commercial scraping software. We categorized videos based on the usefulness of their content as "misleading," "personal experience," or "useful" and used the Patient Education Materials Assessment Tool for Audiovisual Materials to evaluate the video quality regarding understandability and actionability. By purposive sampling, we selected 6 videos and analyzed the content of 100 randomly selected user comments per video to understand the extent of self-identification with ADHD behavior among the viewers. All qualitative analyses were carried out independently by at least 2 authors; the disagreement was resolved by discussion. Using SPSS (version 27; IBM Corp), we calculated the interrater reliability between the raters and the descriptive statistics for video and creator characteristics. We used one-way ANOVA to compare the usefulness of the videos.

Results: We assessed 50.4% (63/125) of the videos as misleading, 30.4% (38/125) as personal experience, and 19.2% (24/125) as useful. The Patient Education Materials Assessment Tool for Audiovisual Materials scores for all videos for understandability and actionability are 79.5% and 5.1%, respectively. With a score of 92.3%, useful videos scored significantly higher for understandability than misleading and personal experience videos (P<.001). For actionability, there was no statistically significant difference depending on the videos' usefulness (P=.415). Viewers resonated with the ADHD-related behaviors depicted in the videos in 220 out of 600 (36.7%) of the comments and with ADHD in 32 out of 600 (5.3%) of the comments. Self-attribution of behavioral patterns varied significantly, depending on the usefulness of the videos, with personal experience videos showing the most comments on self-attribution of behavioral patterns (102/600, 17% of comments; P<.001). For self-attribution of ADHD, we found no significant difference depending on the usefulness of the videos (P=.359).

Conclusions: The high number of misleading videos on ADHD on TikTok and the high percentage of users who self-identify with the symptoms and behaviors presented in these videos can potentially increase misdiagnosis. This highlights the need to critically evaluate health information on social media and for health care professionals to address misconceptions arising from these platforms.

KEYWORDS

social media; health information; misinformation; attention-deficit/hyperactivity disorder; ADHD; TikTok

Introduction

Social media use is continuously rising, and by early 2024, the number of social media users had reached over 5 billion worldwide, with users spending on average approximately 2.5 hours on social media every day [1]. Besides the popular platforms such as Facebook, YouTube, WhatsApp, and Instagram, the relatively new social media platform TikTok has seen a rise in popularity and users in the last few years. In 2024, it ranked fifth in the most popular social networks worldwide, with approximately 1.6 billion users per month [1] and was the most downloaded social media app in recent years [2]. TikTok differs from other social media or social networking platforms in the sense that users can publish posts only in the form of pictures or short videos, and that it is mainly used for entertainment. In addition, video descriptions are rather short.

XSL•FO
RenderX

While it is possible to search for specific videos, hashtags, or creators, TikTok's main feature is its algorithm, which creates a so-called "For You Page" for the user, by making personalized video recommendations based on analysis of previous engagement with videos [2,3]. Originally, TikTok primarily targeted Gen Z but expanded and diversified its user base during the COVID-19 pandemic [3]. Nonetheless, according to data from 2023, 71% of its user base is aged 18 to 34 years and therefore younger than the user base of many other popular social media platforms [4-6].

TikTok is mainly used for networking and entertainment, but increasingly also for both sharing and searching for health-related information online [7-9]. Social media offers the possibility to connect with other patients or a community with similar health conditions, seek emotional support, share personal experiences concerning diseases or medical treatments, and obtain information in an easily understandable format, such as pictures and short videos [7,10].

On TikTok, the popularity of health-related content began with the COVID-19 pandemic, but now there is information on a variety of health topics to be found, including diabetes, dental care, cancer, and mental health issues such as depression, autism spectrum disorder, and attention-deficit/hyperactivity disorder (ADHD) [8,9]. Especially the topic of ADHD has gained popularity on TikTok in recent years. The growing interest is evident from the increase in content under the hashtag "#adhd" in 2023 from 2 million to over 3 million videos within only 12 months [11].

Many TikTok videos about ADHD feature creators sharing their personal experience of the disorder. This can have many benefits for people with ADHD, as it can raise awareness about the disorder, help people understand symptoms and behavior typical for ADHD, and reduce stigmatization [12]. In addition, getting more information on the disorder and seeing and hearing people talk about their experiences with it can lower the threshold for seeking a diagnosis and potential treatment for individuals suffering from ADHD. A diagnosis is important to receive appropriate treatment and to target symptoms [13].

However, health information on social media and particularly TikTok should be viewed with caution, as several studies have shown a high percentage of misinformation on different health issues on social media [14,15]. Specifically regarding ADHD and TikTok, Yeung et al [16] have shown that content about ADHD on TikTok was predominantly misleading (52%), which includes inaccurate and overgeneralized information. Only 21% of the analyzed videos were considered useful, while the rest showed personal experiences [16]. With the increased "popularity" or "virality" of ADHD-related videos on TikTok in the last few years, and with the rapidly increasing number of videos on that topic, a repeated and updated analysis about misleading information tied to ADHD is needed.

Misleading information about ADHD on TikTok often includes incorrect descriptions of ADHD symptoms, the overpathologizing of behaviors that are common in the general population, and even "ADHD tests" that falsely claim to be able to provide diagnoses. Such misinformation can lead to misunderstandings about the disorder and even influence viewers' behavior. While the health belief model is usually used to explain preventive health behavior, it can also be applied to understand the behavior of viewers of ADHD content on TikTok. The health belief model consists of 6 constructs: perceived susceptibility of the disease, perceived severity of the disease, perceived benefits, perceived barriers, self-efficacy, and cues to action [17]. Misleading content on ADHD, including the overpathologizing of behaviors that are common in the general population, may lead to the trivializing of the disorder, and viewers might perceive ADHD severity and burden of disease as lower. In addition, TikTok's algorithm increases exposure to such videos, potentially increasing self-observance of certain own behaviors and therefore raising viewers' perceived susceptibility to ADHD. Misinformation about ADHD and its diagnostic process, as well as personal experience reports and depictions of stigmatization toward ADHD, can affect viewers' perceptions of the barriers and benefits of seeking a formal diagnosis and potentially lead to inappropriate health behaviors like self-identifying with ADHD symptoms and even self-medicating, as a study has shown that for mental illness, a high prevalence of undiagnosed individuals was self-medicating [18]. While only a medical professional can diagnose ADHD, this self-identification with symptoms and behaviors typical of ADHD is often referred to as "self-diagnosing" and is used accordingly in this study [12,19]. This self-identifying behavior can result in stress in people who perceive themselves as affected, which can cause comorbidities to go unrecognized and therefore delay receiving appropriate treatment and can even increase stigmatization by minimizing the effects that ADHD can have on affected people [12,20,21]. However, the effect of TikTok videos about ADHD on viewers has not yet been studied, and it remains unclear how often recipients identify with the ADHD information shared on TikTok and if, or how often, they may even self-diagnose.

The objectives of this study are (1) to analyze the quality and usefulness of the most popular videos about ADHD on TikTok and (2) to explore how content about ADHD is perceived by conducting an in-depth analysis of the viewers' comments to these ADHD-related TikTok videos.

Methods

Ethical Considerations

This research did not involve the use of clinical data, human participants, or animals. All data analyzed were obtained from publicly available TikTok videos and creator accounts, and the research was conducted in accordance with the European General Data Protection Regulation. Creators' and users' names and other personally identifiable information were anonymized. As there was no direct participation of patients, no interaction with users, and no expected negative effects on creators, an ethical review was not deemed necessary, as per the RatSWD recommendations on research ethics self-assessment [22].

Part 1: Video Analysis

Video Inclusion and Search Strategy

The methods used for the video analysis were based on Yeung et al [16]. They conducted their search for 100 videos on July

XSL•FO
RenderX

18, 2021 and in accordance with this, we aimed at including at least 100 videos on ADHD uploaded after July 18, 2021, in our analysis. Our inclusion criteria were videos that addressed ADHD and contained the word "adhd" in either the title or the hashtags. We excluded videos uploaded before July 19, 2021, videos other than the English language, videos that did not include audio or written text, videos that had the comment function disabled, videos that contained advertisements for products or services, or videos that primarily dealt with other diseases or comorbidities instead of ADHD.

We searched the TikTok mobile app on November 28, 2023, and November 29, 2023, with the hashtag "#adhd" for videos about ADHD. The results were sorted for likes count, with the most popular videos (the videos receiving the most "likes") displayed at the top of the search.

Data Extraction

We downloaded or screen-recorded the 130 most-liked videos and extracted video data automatically using a commercial scraping software ("clockworks/free-tiktok-scraper," provided by Apify) [23]. Extracted metadata on the video creators included the username of the creator, follower count, creator account type (private or public account, verified account, and business account), how many accounts the creator follows, origin of the creator, and the creator's biography. Furthermore, metadata on the videos included the weblink of the video, number of likes or views or shares or saves or comments, time of video upload, hashtags, title, duration, and country of origin.

Business accounts are public profiles for brands, companies, or anyone who wants to promote their business (products or services) and use TikTok's marketing tools. Verified accounts are accounts with a blue checkmark, which helps distinguish if the creator's identity was confirmed and it is not a copycat, fan account, etc, indicating authenticity and credibility.

All videos were assessed for inclusion according to the aforementioned inclusion criteria.

Rating of Usefulness

Following the methodology of Yeung et al [16], all included videos' contents were categorized as either "misleading," "personal experience," or "useful." Videos were considered misleading if they contained false information on ADHD and if they showed symptoms not considered typical for ADHD (based on the German S3 guideline on ADHD and the *International Classification of Diseases, 11th Revision*) [24,25]. They were also considered misleading if they were overgeneralizing, for example, stating that "everybody with this symptom or behavior has ADHD," or "everybody with ADHD has this symptom or behaves like this." The category "misleading" therefore included, for example, videos claiming to provide a diagnostic test for ADHD, misleading points of view with wrong depictions of symptoms, and overgeneralizing statements. We considered videos "personal experience" if they described the creator's personal experience with ADHD without being overgeneralizing, and videos as "useful" if they contained correct information on ADHD or correctly depicted symptoms and behaviors.

Videos could only be assigned to one of the three categories. Videos that depicted a personal experience but also contained misleading statements or useful information were categorized as misleading (or useful) rather than as personal experience. Videos, therefore, could only be categorized as personal experience if they were neither misleading nor useful.

Three members of the interdisciplinary research group independently rated the usefulness of the videos, using the German S3 guideline on ADHD and the *International Classification of Diseases, 11th Revision* [24,25]. Any disagreements were resolved through discussion. The research group comprised a physician, a clinical psychologist, and researchers in health science.

Quality Assessment

We assessed the informational quality of the videos using the Patient Education Materials Assessment Tool for Audiovisual Materials (PEMAT-A/V), a systematic method to assess the understandability and actionability of audiovisual patient education materials. Its goal is not to rate the quality of the information provided, but to assess if patients or users will be able to understand and act on the provided information. The PEMAT-A/V consists of 13 items assessing understandability and 4 items assessing actionability [26]. The items are scored as "agree=1 point" or "disagree=0 points" (and some items additionally have the option to choose "not applicable"). Final understandability and actionability scores are calculated by summing up the total achieved points and dividing them by the total possible points. The final score is reported as a percentage of the total possible points. The PEMAT-A/V tool was selected because it is well-suited for evaluating audiovisual health information and not only assesses understandability but also actionability. However, 3 of the 17 items cannot be rated if the material or video is shorter than 60 seconds, which is a common occurrence with TikTok videos.

Quality assessment was conducted by 2 members of the research group independently, and disagreement was resolved by discussion.

Part 2: Comment Analysis

Data Extraction

By purposive sampling, we selected 6 videos, including 2 misleading videos, 2 useful videos, and 2 videos categorized as personal experience. We selected the videos based on the highest likes count in each category but made sure not to include 2 videos from 1 creator. We scraped a minimum of 900 first-level comments of these videos using a commercial scraping software ("clockworks/tiktok-comments-scraper," provided by Apify) [23]. From the retrieved comments, a random sample of 100 comments per video was drawn using SPSS (IBM Corp). Scraped data on the comments included the comment text, the username of the person commenting, the time the comment was made, and the number of likes the comment received. We translated comments that were written in languages other than English, French, Spanish, Italian, or German using DeepL Translator (DeepL SE).

XSL•FO
RenderX

Content Analysis

We analyzed the content of user comments to investigate how often self-identification with ADHD-related behavioral patterns and self-diagnosis of ADHD among viewers occurred. The comments were categorized into 16 inductively derived categories, including 10 distinct categories directly regarding ADHD (1-10) and 6 rather technical categories (11-16). These 16 categories are explained in Table 1.

Table . Comment categories.

No.	Comment category	Explanation
1	Self-attribution of behavioral patterns	The person commenting attributes the shown behavioral patterns to themselves.
2	Self-attribution of ADHD[a]	The person commenting attributes ADHD to themselves.
3	Attribution of 'ADHD typical behavioral patterns' to others	The person commenting attributes the shown behavioral patterns to another person.
4	The attribution of ADHD to others	The person commenting attributes ADHD to another person.
5	"Behaviors don't apply"	The person commenting does not relate to the shown behavioral patterns.
6	"I personally suffer from ADHD"	The person commenting states that they have ADHD.
7	"I personally do not suffer from ADHD"	The person commenting states that they do not have ADHD.
8	Questions on ADHD	The person commenting asks a question on ADHD topics.
9	Personal experience	The person commenting shares a personal story.
10	Shown behaviors are not typical for ADHD	The person commenting states that the shown behavioral patterns are not specific to people with ADHD, but that everybody behaves like that.
11	Comments on video content	The person comments on an aspect of the video that is not related to ADHD.
12	Tagging of other users	The person commenting tags another user.
13	Jokes or irony	The person commenting makes a joke or uses irony.
14	Others	Comments that do not fit the other categories.
15	Not interpretable	The comment can either not be translated appropriately into English or the true meaning of the comment cannot be understood.
16	Empty comments	Comments that were empty (no text, emojis, etc). The mechanism behind the scraping process did not explain why comments appeared empty.

[a]ADHD: attention-deficit/hyperactivity disorder.

Multiple categories could be ascribed to 1 single comment; for instance, a comment might both tag another user and include self-attribution of behavioral patterns (eg,*"@Kate this is me"*). However, a comment cannot self-attribute behavioral patterns and additionally say that behaviors do not apply, and since the use of irony alters the meaning, for our analysis, a comment also cannot self-attribute behavioral patterns of ADHD and use irony. Similarly, a comment could not simultaneously assert that the commenter both suffers from and does not suffer from ADHD.

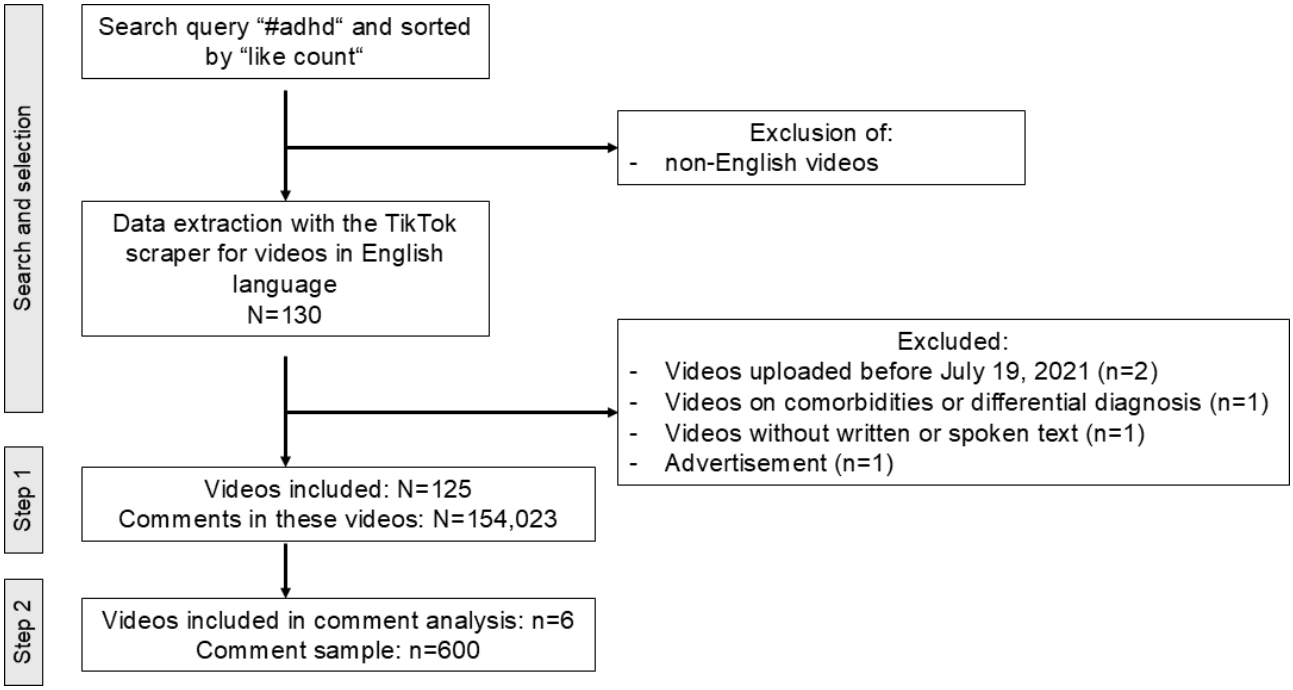
Two members of the research group conducted the comment categorization independently, and disagreement was resolved by a third researcher and by discussion in the research group.

Statistical Analysis

For both parts of this study (part 1: video analysis and part 2: comment analysis), we calculated the interrater reliability and descriptive statistics.

Fleiss κ was used to calculate the interrater reliability between the 3 raters for the video categorization, and Cohen κ to calculate the interrater reliability between the 2 raters each for the PEMAT-A/V assessment and the comment categorization. We consider a κ statistic of >0.4 as moderate agreement and a κ statistic of >0.6 as substantial agreement between the raters [27].

XSL•FO
RenderX



To compare video characteristics and PEMAT-A/V scores between the useful, misleading, and personal experience videos, we used one-way ANOVA. For data with variance heterogeneity, the Welch ANOVA was used. We conducted post hoc analyses using the Games-Howell post hoc analysis. To compare the comments between useful, misleading, and personal experience videos, we used chi-square tests of independence. We considered a *P* value of $P<.05$ as significant for all analyses.

Statistical analyses were performed using SPSS (version 27).

Results

A total of 130 videos were scraped for information and after assessing inclusion and exclusion criteria, 125 videos were included in the final analysis, and 6 videos were selected and included in the comment analysis. The methodological approach of the video search and selection is illustrated in the flowchart in Figure 1.

Figure 1. Flowchart of video and comment inclusion.

Part 1: Video Analysis

Video and Creator Characteristics

The 125 included videos were uploaded by 73 different creators from 13 different countries. Most videos were created in English-speaking countries (105/125, 84%) with the highest percentage in the United States (48/125, 38.4%). Most creators only had 1 video in the included 125 most-liked videos (54/73, 74%), but on average, creators had 1.7 (SD 1.54; range: 1‐8) videos in the most liked videos.

The videos had a mean duration of 44 seconds (SD 60 s), with the shortest video only lasting 7 seconds and the longest video 9 minutes and 47 seconds. On average, the videos had a total of 10.16 million views (SD 9.75 million) and 1.21 million likes (SD 1.16 million).

For more information on the creators and videos, see Table 2 and column "Total" in Table 3.

[a]PEMAT-A/V: Patient Education Materials Assessment Tool for Audiovisual Materials.

Usefulness and Quality of Videos

Of the 125 included videos, 50.4% (63/125) of videos were rated misleading, 30.4% (38/125) showed a personal experience, and 19.2% (24/125) were useful. Agreement between raters was moderate, with a κ statistic of 0.529 (P<.001).

Useful videos often showed comorbid disorders that can occur alongside ADHD, such as auditory processing disorder, and

XSL•FO
RenderX

explained relevant symptoms. Other useful videos explained relevant ADHD symptoms, such as impulsivity, difficulty focusing on and completing tasks, and hyperactivity. Personal experience videos mainly showed the creators' point of view as individuals affected by ADHD. They showed the creators experiencing distraction while doing a task, procrastinating, being restless, experiencing self-doubt, and feelings of being overwhelmed. Misleading videos included videos that showed symptoms that can be related to ADHD but can also be "normal" behavior, such as being late or poor time management, fidgeting with random objects, and forgetfulness. Other misleading videos wrongly depicted anxiety as nervousness and as a symptom of ADHD, not a possible comorbidity; or creators explained "ADHD paralysis," which they described as "my brain won't let me do this task." Some videos also included so-called "ADHD tests," suggesting the viewers have ADHD if they experience the mentioned symptoms.

The 125 videos score on average 79.5% (SD 18.7%) in the PEMAT-A/V understandability domain, and 5.1% (SD 18.0%) in the actionability domain. For 3 PEMAT-A/V items, the agreement between raters could not be calculated (items 12, 19, and 25). The raters were in complete agreement for these items, as according to the PEMAT-A/V guidelines, they should be marked as "not applicable" if the audiovisual material is a video and if no tables, graphs, and charts are used. For the items with a significant agreement (11/17), the mean agreement was moderate, with a mean κ statistic of 0.508 (SD 0.187).

Video characteristics and quality for useful, misleading, and personal experience videos are described in Table 3.

Useful videos had the highest PEMAT-A/V understandability score, with an average score of 92.3% (SD 10.4%; $P<.001$). Post hoc analysis revealed significantly lower PEMAT-A/V understandability scores of the misleading and personal experience videos compared to the useful videos (mean difference 18.2%, $P<.001$ for misleading and 12.0%, $P=.002$ for personal experience videos). There was no statistically significant difference between the personal experience and the misleading videos (mean difference 6.4%; $P=.190$), and in the PEMAT-A/V actionability scores for useful, misleading, and personal experience videos ($P=.415$; Table 3).

Misleading videos were more popular than useful videos, as they had significantly more likes, views, and comments than useful videos (mean difference 476,113 likes, $P=.047$; 5,091,667 views, $P=.012$; 11,733 comments; $P=.016$). They also had more comments than videos on personal experiences.

Part 2: Comment Analysis

On average, comments were assigned to 1.4 categories each, leading to a total of 840 assigned categories. Comments were most often assigned to "self-attribution of behavioral patterns" (220/600, 36.7%), followed by "personal experience" (93/600, 15.5%), regarding the categories directly related to ADHD. Regarding the technical categories, commenting persons most frequently "tagged other users" (115/600, 19.2%). Table 4 shows an overview of the frequency of all categories.

XSL•FO
RenderX

Table . Frequency of comments for all videos and divided into misleading, useful, and personal experience videos (n=600).

Comment category	Total, n (%)	Useful (n=200), n (%)	Misleading (n=200), n (%)	Personal experience (n=200), n (%)	*P* value
Self-diagnosis	252 (42)	79 (39.5)	64 (32)	109 (54.5)	<.001
Self-attribution of behavioral patterns	220 (36.7)	67 (33.5)	51 (25.5)	102 (51)	<.001
Self-attribution of ADHD[a]	32 (5.3)	12 (6)	13 (6.5)	7 (3.5)	.359
Attribution of "ADHD typical behavioral patterns" to others	9 (1.5)	2 (1)	0 (0)	7 (3.5)	.012
The attribution of ADHD to others	1 (0.2)	1 (0.5)	0 (0)	0 (0)	.367
"Behaviors don't apply"	8 (1.3)	5 (2.5)	3 (1.5)	0 (0)	.090
"I personally suffer from ADHD"	28 (4.7%)	14 (7%)	5 (2.5%)	9 (4.5%)	.102
"I personally do not suffer from ADHD"	25 (4.2%)	9 (4.5%)	5 (2.5%)	11 (5.5%)	.311
Questions on ADHD	15 (2.5%)	10 (5%)	3 (1.5%)	2 (1%)	.020
Personal experience	93 (15.5%)	51 (25.5%)	15 (7.5%)	27 (13.5%)	<.001
Shown behaviors are not typical for ADHD	58 (9.7%)	14 (7%)	35 (17.5%)	9 (4.5%)	<.001
Comments on video content	71 (11.8%)	14 (7%)	35 (17.5%)	22 (11%)	.005
Tagging of other users	115 (19.2%)	33 (16.5%)	40 (20%)	42 (21%)	.486
Jokes or irony	53 (8.8%)	27 (13.5%)	20 (10%)	6 (3%)	<.001
Others	23 (3.8%)	7 (3.5%)	5 (2.5%)	11 (5.5%)	.282
Not interpretable	27 (4.5%)	8 (4%)	17 (8.5%)	2 (1%)	.001
Empty comments	8 (1.3%)	3 (1.5%)	0	5 (2.5%)	.09

[a]ADHD: attention-deficit/hyperactivity disorder.

To assess the prevalence of viewers "self-diagnosing" in the comments, we looked further into the categories "self-attribution of behavioral patterns" and "self-attribution of ADHD." Agreement between raters for the category "self-attribution of behavioral patterns" was substantial, with a κ statistic of 0.638 (*P*<.001) and agreement for the category "self-attribution of ADHD" was moderate, with a κ statistic of 0.544 (*P*<.001). Examples of comments assigned to these categories include "wait so ur saying I might have adhd?" "Does that mean I have ADHD cause I do that," and "me 100% of the time," showing a varying degree of self-identification with the shown behavior or the disorder. Of the 600 comments, 220 (36.7%) comments solely indicated a self-attribution of ADHD-related behavioral patterns, and 32 of the 600 (5.3%) comments, a self-attribution of ADHD. In combination, 252 of the 600 (42%) comments indicate some sort of "self-diagnosis" with ADHD, which is shown in Table 3 under the newly summarized comment category "self-diagnosis."

The number of comments indicating a possible self-diagnosis varied between misleading, useful, and personal experience videos, and the statistical analysis showed a significant association between the usefulness of the videos and the number of comments indicating a possible self-diagnosis. The strength of association was small (χ^2_2=21.55; *P*<.001; V=0.190). Comments indicating a possible self-diagnosis were most common in videos categorized as personal experience (109/200, 54.5%), followed by useful (79/200, 39.5%) and misleading videos (64/200, 32%).

If differentiated between self-attribution of behavioral patterns and the self-attribution of ADHD, there was a significant association between the usefulness of the videos and the number of comments indicating a self-attribution of behavioral patterns. The strength of association is small (χ^2_2=29.3; *P*<.001; V=0.221). Comments indicating a self-attribution of behavioral patterns were most common in videos categorized as personal experience (102/200, 51%), followed by useful (67/200, 33.5%) and misleading videos (51/200, 25.5%). The association between usefulness and the number of comments indicating a self-attribution of ADHD was not statistically significant (χ^2_2=2.05; *P*=.359; V=0.058).

XSL•FO
RenderX

Besides the comments hinting towards a potential self-diagnosis, the frequency of other comments was also found to be associated with the usefulness of the videos. The attribution of behaviors typical for ADHD to others was also most common in personal experience videos (7/200, 3.5%), followed by useful and misleading videos (2/200, 1% and 0/200, 0% respectively; χ^2_2=8.799; *P*=.012; V=0.121). Questions on ADHD, comments with personal experiences, and joking or ironic comments were most common in useful videos (χ^2_2=7.79, *P*=.02, V=0.114; χ^2_2=25.654, *P*<.001, V=0.207; χ^2_2=14.198, *P*<.001, V=0.154, respectively; Table 3). Comments on how the shown behavior is not typical for ADHD, comments on the video content but unrelated to ADHD, as well as not interpretable comments were most common in misleading videos (χ^2_2=21.797, *P*<.001, V=0.191; χ^2_2=10.767, *P*=.005, V=0.134; χ^2_2=13.264, *P*=.001, V=0.149, respectively; Table 4).

Discussion

Principal Results

Many users turn to TikTok for health information or even health advice [8,28]. However, many studies have shown that health-related information on social media, particularly TikTok, is often inaccurate or misleading [14-16]. Given that the number of TikTok videos on ADHD has increased substantially over the recent years, we have analyzed the most popular TikTok videos on ADHD regarding their usefulness, understandability, and actionability as health information. In addition, we have explored viewer perceptions of these videos by analyzing the comments.

The most popular videos on ADHD between July 2021 and November 2023 averaged 10.2 million views, which is a considerable increase from the 2.8 million views that Yeung et al [16] reported in their study in 2022. This suggests that TikTok videos on ADHD are trending more than ever. We found a high proportion of these ADHD-related TikTok videos to be misleading (63/125, 50.4%), which is in line with the results of a study by Yeung et al [16] from 2022, where 52% of the included videos were misleading. While the prevalence of misleading information varies by health topic [14], many other studies report high rates of misinformation, for example, Aragon-Guevara et al [15] found 73% of videos providing informational content on autism to be either inaccurate or overgeneralizing.

This study shows that the information provided in TikTok videos on ADHD is easily understandable, as evidenced by high PEMAT-A/V understandability scores averaging 79.5%. While videos classified as useful scored significantly higher than misleading and personal experience videos, even misleading videos achieved an understandability score of 74%. Since the PEMAT-A/V does not assess the accuracy of the information, this indicates that potential misinformation was presented in an easily understandable way, possibly facilitating the distribution of false information. PEMAT-A/V actionability scores, however, were generally low. TikTok videos might provide information that is easy to understand, but rarely give recommendations or describe specific actions for the viewers to take, for example,“see your health care provider” or “take this medication.” Yeung et al [16] also reported low actionability scores, although their scores were higher than we found in this analysis. In particular, the useful videos in the study by Yeung et al [16] showed higher actionability scores (27.8%), which could be because a higher percentage of useful videos in their study was created by health care professionals (7/21, 33.3%), who might be more inclined to recommend appropriate action compared to private individuals. In comparison, only one of the useful videos in our analysis was created by a health care professional (1/24, 4.2%).

The low actionability of ADHD videos on TikTok raises concerns. Viewers are constantly provided with easily understandable information on symptoms and might recognize those symptoms in themselves. But the lack of clear guidance or actionable steps—such as encouragement to consult a health care professional or to seek a professional diagnosis and guidance on how to do so—may lead to insecurity and act as a barrier to a formal diagnosis. Instead, viewers might self-diagnose and potentially also self-treat [18]. This is especially problematic for viewers with low health literacy. Clear guidance on subsequent actions, such as seeking a diagnosis and management of symptoms, would be highly beneficial, as these audiences might have difficulties accessing other health information and resources.

Our study found that misleading videos were the most popular, receiving the highest engagement through likes, views, and comments. However, the difference in likes and views between misleading videos and videos on personal experience was not significant. This is surprising, as other studies found that first-person and personal experience videos receive the most engagement, suggesting that social media users are drawn to relatable videos created by individuals who are personally affected by ADHD [16,29]. However, videos on personal experience that were misleading or overgeneralizing were categorized as misleading. Consequently, a substantial number of misleading videos also showed personal experiences, which might be one of the reasons why misleading videos in our analysis showed the highest engagement rates. The popularity of misleading videos is concerning. It has been shown that videos with high engagement are more likely to be further promoted by TikTok’s algorithm [30]. They appear more frequently on people’s For You Page, which increases their reach, can lead to even higher engagement rates, and consequently means that the misleading content is being distributed to an even wider audience. In addition, the algorithm pushes this content especially to viewers who have shown a previous interest in the topic or have engaged with similar videos. Repeatedly being shown individuals affected by ADHD, as well as mainly wrong depictions of symptoms, might increase viewers’ perceived susceptibility to ADHD, and together with the perceived low severity of ADHD that the misleading videos suggest, this might potentially increase self-identification [17].

Our analysis shows that misleading videos not only received the most comments in general, but compared to useful and personal experience videos, they also received significantly more comments that stated that the behaviors depicted were

XSL•FO
RenderX

common to everyone, not just people with ADHD. A substantial number of people, therefore, commented to criticize the video, or to identify the information in the video as misleading. It is encouraging that many viewers are skeptical or disagree with misleading videos, and not all viewers self-identify with ADHD behaviors. However, their engagement with the video increases the reach of the video nonetheless.

A US survey showed that the most common reasons for using TikTok for health-related information are to receive advice from other people with similar health conditions, to receive support, or to get information on their disorders. Communicating with physicians and health care professionals ranked rather low on this list of reasons [8], explaining why personal experience videos might be so popular and why videos from health care professionals might be underrepresented in our sample of the most popular videos.

Since TikTok is primarily used for entertainment, it is not surprising that the explorative comment analysis revealed some comments as either joking or (supposedly) ironic in meaning (53/600, 8.8%). Many comments were also tagging other users (115/600, 19.2%), which can be understood as a form of online communication. Tagging of users is one way of sharing the video and many viewers were communicating with friends or acquaintances in the comments to the videos. Without further information, the interpretation of these comments is difficult, as the meaning of tagging another user can vary. Apart from sharing the video, it can also be interpreted as “that’s you” or even “that’s me,” or just to show that one might find this video interesting.

Viewers resonated with the behaviors depicted in the videos in a substantial number of comments, particularly in the personal experience videos. These videos, including “point-of-view” videos, show people with ADHD in everyday situations. Many viewers attributed these allegedly ADHD-typical shown behaviors to themselves, by commenting with phrases like “I’m so her,” “I do this all the time,” or “It’s like watching myself.” However, while comments relating to the depicted behaviors were most prevalent in personal experience videos, they appeared in the useful and misleading videos as well. Regarding the actual self-attribution of ADHD in the comments (eg, “I think I have ADHD,” “I really need to get evaluated,” or “Ok I counted and this is the 12th sign that I have ADHD”), the comments were less frequent and there was no significant difference between useful, misleading, and personal experience videos. These comments about relating to the behavior labeled as typical for ADHD in the video do not necessarily indicate an actual belief in having ADHD. As TikTok is a platform mainly used for entertainment, not all comments can be taken seriously. However, if many people who are not affected by ADHD relate to the shown behaviors, this can lead to an oversimplification of the disorder, potentially increasing stigmatization of affected people and reinforcing existing stereotypes rather than improving mental health understanding [12,20,21].

False assumptions that people have ADHD might lead more people to seek a professional diagnosis, potentially resulting in longer waiting times for diagnosis and an increased risk of overdiagnosis [31]. On the other hand, some individuals might just accept their self-diagnosis and therefore not seek a professional diagnosis, risking that comorbidities and differential diagnoses could be overlooked. In addition, if people believe that they are suffering from a disorder without getting the proper care and treatment, this can cause significant stress and anxiety [20,21]. Some individuals might even try to treat themselves without consulting a health care professional, possibly with inappropriate treatment options and medication.

TikTok is a platform where everyone can share videos and where the information in these videos is not fact-checked. Users, therefore, need to be cautious when watching videos on health-related topics and critically assess the information provided. Media and health literacy are needed for this, especially for children and teenagers, as they are the main users of TikTok. Even if TikTok users do not intentionally search for health information on TikTok, the probability of unintentionally being exposed to health information is high [8]. Users also underestimate their own susceptibility to misinformation, which poses a higher risk of following false health information, both consciously and subconsciously [8]. Furthermore, TikTok’s algorithm is designed to promote content based on the viewer’s previous interactions with similar content, as well as content with a high engagement rate, as is the case for misleading videos on ADHD [30]. Continuous exposure to misleading content that focuses on certain diseases or disorders can lead to distorted perceptions of the viewer’s own health and can worsen their mental health, especially for more impressionable viewers such as children and teenagers. The low actionability of these videos, which depict disorders without offering guidance or coping strategies, can further exacerbate these issues.

To counteract the vast amount of misleading information currently available on social media, it could be helpful if more health care professionals and educators step up and upload videos on health-related topics. These videos should be engaging, as we see that videos by health professionals are considered more boring, often lacking the entertainment value, trending sounds, and other creative and engaging strategies that other creators use [28]. By providing reliable resources, warning about the risk of, and debunking misinformation, health care professionals and organizations could become trustworthy information sources for TikTok users seeking health information. Although TikTok itself does not fact-check content, it does display a warning at the top of the search results indicating that TikTok is not a substitute for medical advice. However, this warning is only visible through the search function and not on videos that appear directly on the For You Page. Expanding these warnings to appear with all health-related videos could encourage viewers to critically assess the information and make more informed health decisions. In addition, it is important for health professionals to address social media–driven misconceptions and correct misinformation that potentially originate from social media during patient interactions.

Limitations

We used the PEMAT-A/V to assess the informational quality of the videos. This tool can be used to assess the

XSL•FO
RenderX

understandability and actionability of audiovisual patient education material. However, the TikTok videos included in this analysis were on average 44 seconds long, and 3 of the 13 understandability domains of the PEMAT-A/V require videos to be at least 60 seconds long to be rated. The PEMAT-A/V provides an overview of the quality of the included videos as informational or educational material; however, it is generally not ideally suited for such short videos, whose intended goal is more towards entertainment than education. However, the PEMAT-A/V does not only assess understandability but also actionability of the health information and is considered one of the better online health assessment tools [32].

Due to the purposive sampling strategy used for the comment analysis, generalization of the results to other videos on ADHD on TikTok is not possible. The videos included in the comment analysis were selected based on the categories of usefulness assigned beforehand and the analyzed engagement rate of the videos, but other videos could have yielded different results and therefore would have potentially led to different conclusions regarding the self-identification of viewers with the disorder.

In addition, the categorization of the comments on TikTok proved difficult. Viewers have diverse cultural and linguistic backgrounds; they are nonnative English speakers or post comments in other languages; abbreviate words or phrases; and use humor, irony, emojis, and slang. These factors, together with the varied professional backgrounds, ages, and social media familiarity of the researchers, led to differing interpretations of some comments, necessitating discussions to reach a consensus. TikTok is primarily a platform used for entertainment, and while we assessed humor and irony and subsequently excluded those comments, it remains unsure how many commenters really are serious about their self-diagnosis. It is possible that despite the extensive discussion between the 5 different researchers and efforts to ensure interrater reliability, some comments were misunderstood and miscategorized, and that the number of viewers potentially "self-diagnosing" therefore differs. Nevertheless, the analysis gives a valuable first impression of how TikTok users perceive and engage with videos that, to a great extent, contain false and misleading information.

Conclusions

ADHD is a popular topic on TikTok and videos on the topic are viewed by millions of users. While social media and TikTok have the potential to be an easily accessible and free source of health information for the population, the high prevalence of misleading and overgeneralizing content related to ADHD on TikTok is concerning. The widespread dissemination of this easily understandable information through the TikTok algorithm, together with the lack of actionable guidance in the videos, presents the risk of false self-identification and misdiagnosis with ADHD and can cause unnecessary stress, delayed appropriate treatment, unrecognized comorbidities, and increased stigmatization. It is important for viewers to critically evaluate information on health-related topics on social media and to assess the source or creator of this information. For health care professionals, it is important to address misconceptions arising from such platforms, and it would be beneficial for them to also use TikTok and produce engaging and accurate content to counterbalance the prevalent misinformation.

Abstract

Background: The COVID-19 pandemic emerged in the digital age and has been called the first “data-driven pandemic” in human history. The global response demonstrated that many countries had failed to effectively prepare for such an event. Learning through experience in a crisis is one way to improve the crisis management process. As the world has returned to normal after the pandemic, questions about crisis management have been raised in several countries and require careful consideration.

Objective: This review aimed to collect and organize public health professionals’ experiences in crisis communication to the public during the COVID-19 pandemic.

Methods: We searched PubMed, MEDLINE, CINAHL, Web of Science, Academic Search Complete, PsycINFO, PsycARTICLES, and Communication Abstracts in February 2024 to locate English-language articles that qualitatively investigated the difficulties and needs experienced by health professionals in their communication activities during the COVID-19 pandemic.

Results: This review included 17 studies. Our analysis identified 7 themes and 20 subthemes. The 7 themes were difficulties in pandemic communication, difficulties caused by the “infodemic,” difficulties in partnerships within or outside of public health, difficulties in community engagement, difficulties in effective communication, burnout among communicators, and the need to train communication specialists and establish a permanent organization specializing in communication.

Conclusions: This review identified the gaps between existing crisis communication guidelines and real-world crisis communication in the digital environment and clarified the difficulties and needs that arose from these gaps. Crisis communication strategies and guidelines should be updated with reference to the themes revealed in this review to effectively respond to subsequent public health crises.

Introduction

The COVID-19 pandemic claimed millions of lives. It resulted in a public health crisis and caused economic and social turmoil worldwide. No country, irrespective of region or wealth, was spared the devastating effects of the COVID-19 pandemic. Given that there were no available drugs or vaccines early in the pandemic, communication was an important means of containing the crisis. Even after vaccines were developed, communication to increase trust in the vaccines was central to ending the crisis. Therefore, communication is essential in dealing with a pandemic [1].

Before the COVID-19 outbreak, crisis communication guidelines had been published by the World Health Organization (WHO) [2-4] and crisis communication strategies had been studied by researchers [5-9]. However, when the COVID-19 pandemic started, public health organizations worldwide acknowledged their lack of preparation and training for effective communication during such chaos [10-15]. Furthermore, the communication technology infrastructure has become increasingly complex over the last few decades. Social media platforms now seamlessly connect people to both accurate and false information, which tends to flow to recipients faster than viruses spread [16]. During the COVID-19 pandemic, public health organizations worldwide experienced difficulties with the "infodemic" of misinformation on social media [17]. Before the pandemic, researchers had recognized the importance of management of misinformation and studied countermeasures [18-21]. However, the COVID-19 pandemic highlighted the inexperience of public health agencies in dealing with the influence of misinformation during an emergency [22,23]. Therefore, the COVID-19 pandemic presented public health agencies with unprecedented challenges and highlighted the need to update existing crisis management communication strategies. A crisis is an important opportunity for learning; learning through experience in a crisis is the only way to improve the crisis management process [24,25]. Now that the world has returned to normal following the pandemic, questions requiring reflection have been raised about the crisis management in each country. Therefore, studies are needed to collect and organize data on public health professionals' experiences in crisis communication worldwide during the COVID-19 pandemic. This work is essential for updating crisis communication strategies to prepare for subsequent public health crises.

We conducted a systematic review of qualitative studies that focused on public health professionals' experiences in crisis communication during the COVID-19 pandemic in diverse countries. We examined the difficulties that public health professionals experienced during the COVID-19 pandemic, the challenges they faced in overcoming those difficulties, and the needs to be met in future public health crises. We also discussed the gaps between existing crisis communication guidelines and real-world experiences in the COVID-19 pandemic that need to be bridged going forward.

Methods

Overview

This systematic review followed the guidelines provided in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [26]. In addition, we referred to the Sample, Phenomenon of Interest, Design, Evaluation, Research type tool for the synthesis of qualitative evidence [27]. The protocol was previously published [28] and registered with the international Prospective Register of Systematic Reviews (registration: CRD42024528975).

Literature Search

We searched the following databases on February 7, 2024: PubMed, MEDLINE, CINAHL, Web of Science, Academic Search Complete, PsycINFO, PsycARTICLES, and Communication Abstracts. We filtered our database searches to include articles published from January 1, 2020, to January 31, 2024. We used a combination of keywords with reference to previous studies to search the abstracts in these databases [29-31]: "((government*) OR (ministr*) OR (department*) OR (office*) OR (municipalit*) OR (prefecture*) OR (province*) OR (state*) OR (count*) OR (organization*) OR (institution*) OR (center*) OR (agenc*) OR (sector*) OR (authorit*)) AND ((covid-19) OR (coronavirus) OR (sars-cov-2)) AND ((interview*) OR (focus group*) OR (questionnaire*) OR (survey*)) AND ((communicat*) OR (messag*) OR (inform*) OR (recommend*) OR (announce*)) AND ((qualitative) OR (mix method))."

Study Selection

We used Rayyan software (Qatar Computing Research Institute) [32] to screen the identified studies and automatically remove duplicates. Study inclusion and exclusion criteria are shown in Textboxes 1 and 2.

Titles and abstracts were independently screened to identify eligible studies using selection criteria established by the first author (TO) and the second author (MT). Then, the full texts of the remaining studies were screened independently by the first and second authors. Any disagreements during the screening process were discussed until consensus was reached, assisted by the third author (HO), as necessary.

XSL•FO
RenderX

Textbox 1. Study inclusion criteria.

- The study aim was to investigate public health professionals' experiences in crisis communication during the COVID-19 pandemic in the digital age with the infodemic of misinformation on social media.
- Regarding study content: qualitative studies of communications from governments and public health agencies to the public focusing on addressing the infodemic of misinformation on social media platforms.
- Regarding design: studies with qualitative data (eg, interviews, documents, and free-text questionnaire responses), those that used content analysis of qualitative data, reviews of qualitative studies, and mixed methods studies with qualitative results that met the study aim.
- Studies on individuals (irrespective of age, gender, ethnicity, or nationality), such as officials, health professionals, and researchers working for governments and public health agencies.
- Gray literature (information produced outside traditional publishing and distribution channels, such as conference proceedings and theses) if sufficient information was provided to confirm its eligibility (ie, full-length descriptions of research objectives, methods, results, discussion, and conclusions).
- Papers written in English and conducted from (and including) January 2020.

Textbox 2. Study exclusion criteria.

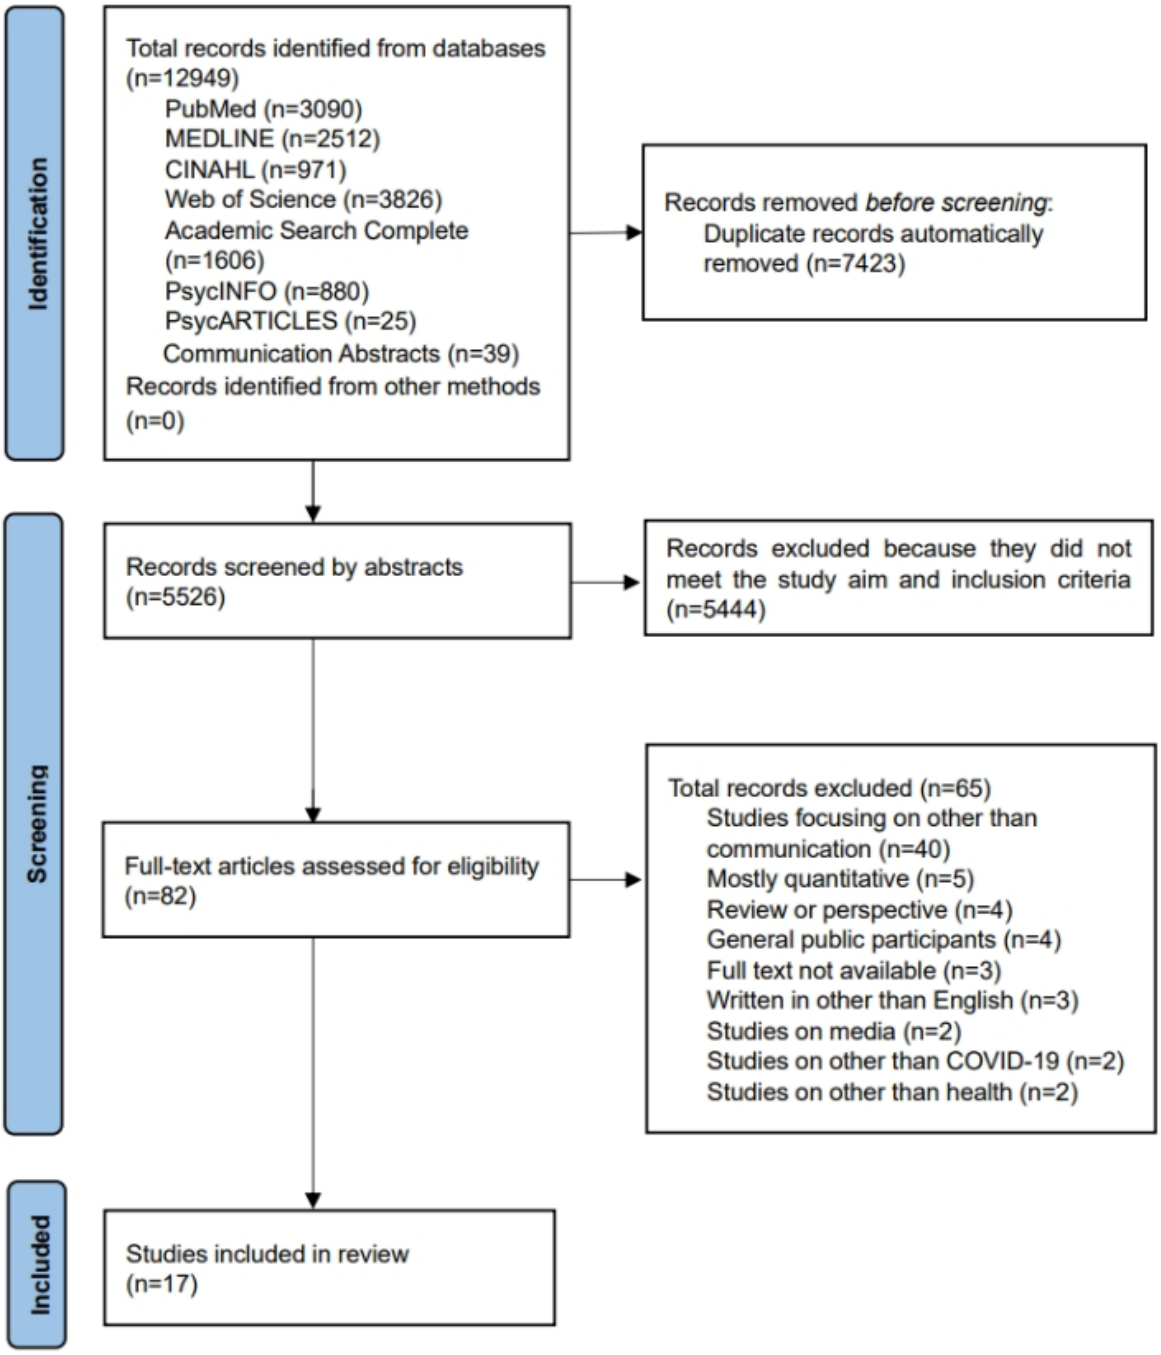
- Quantitative studies with quantitative data (eg, observational and interventional studies)
- Studies on journalists in media companies, patients, and the public
- Studies not published in full-text format
- Non–English-language papers
- Studies that did not meet the study aim that public health professionals' experiences in crisis communication during the COVID-19 pandemic in the digital age with the infodemic of misinformation on social media (eg, those on content analysis of media information, information searches by the public, COVID-19 patient management in hospitals, and patient-provider communication)

Quality Assessment

The Joanna Briggs Institute Critical Appraisal Checklist for Qualitative Research was used to assess the methodological quality of eligible studies [33,34]. This Joanna Briggs Institute checklist assesses the descriptive, interpretative, theoretical, and evaluative validity of qualitative studies. The 10 items of the checklist are evaluated as "yes," "no," "unclear," or "not applicable." The first (TO) and second (MT) authors independently performed quality assessments of the included studies. Any disagreements were discussed until consensus was reached, assisted by the third author (HO) as necessary.

Data Synthesis

Thematic synthesis was used to synthesize the collected data [35]. Thematic synthesis is recommended as a systematic method for synthesizing qualitative evidence [36]. In the first stage, free line-by-line coding of texts and quotations in the results and discussion sections of the included studies was conducted by TO. Next, 2 reviewers (TO and MT) independently grouped similar codes and generated data-driven descriptive themes. Consensus was reached through discussion, and the third reviewer (HO) was consulted when necessary. Finally, TO developed analytical themes by organizing the descriptive themes generated in the previous stage. This process of developing analytical themes involved repeated discussions among TO, MT, and HO.



Results

Study Characteristics

Figure 1 shows the PRISMA flow diagram of the study selection. We included 17 studies in this review. Table 1 shows the characteristics of the included studies. A total of 5 studies were conducted in the United States, 4 in Canada, 2 in Switzerland, and 2 in Iran, and the other studies included participants from Europe, the Middle East, Asia, South America, and Africa. Participants' occupations included communication specialists, medical professionals, scientists, and officials in public health institutions and local municipalities. The median number of study participants was 20 (IQR 12.5-26), and 367 health professionals were represented overall. The time frame in which the data were collected was from March 2020 to December 2022. The included studies showed an overall good methodological quality; the median number of studies classified as "yes" was 8 (IQR 7-9). Results of the quality appraisal are shown in Multimedia Appendix 1 [11,15,37-51].

Data Synthesis

Our analysis identified 242 free codes, which were organized into 41 descriptive themes: 7 analytical themes and 20 subthemes. Multimedia Appendix 2 [11,15,37-51] shows the analytical themes and subthemes, the studies that contributed to those themes, and direct quotations from the included studies to support those themes.

Difficulties in Pandemic Communication

Gap Between Scientific Uncertainty and Expectations of Certainty

The COVID-19 pandemic revealed a gap between the normal reality of scientific uncertainty and political and public expectations of certainty, which made public health communication difficult [11,37-40]. The traditional scientific method of generating, evaluating, and acting on evidence was incompatible with the urgency of the pandemic [11,37]. However, participants were required by policy makers and citizens to provide rapid, definitive conclusions and explanations based on uncertain evidence in an uncertain situation [11,37,38] (quotation 1). This demand contrasted with the "slowness" of science [37]. Changes were unfolding rapidly in terms of scientific knowledge, the spread of the infection, and political, economic, and social conditions, and this required several changes in public health policies over a short time [37,38] (quotation 2). The gap between the uncertainty of science and unrealistic expectations of certainty resulted in public criticism of public health professionals and difficulties in public health communication [11,37-40] (quotation 3).

Communication Challenges in a "Slow Disaster"

Participants described the characteristics of the COVID-19 pandemic as a "slow disaster" [40]. Most disasters are short-lived, but the nature of the COVID-19 pandemic meant that they had to continuously deal with changing circumstances [11,40,41]. In the early stages of the pandemic, citizens cooperated with public health recommendations [11]. However, over time, their patience waned, their trust in public health professionals declined, and compliance worsened [11,40,41] (quotation 4). In addition, health professionals experienced difficulty in using communication to encourage citizens to adopt preventive behaviors amid fatigue from a pandemic with no seeming end in sight [11,40-42] (quotation 5).

Difficulties Caused by the Infodemic

Difficulties in Public Health Activities Due to Misinformation

Misinformation about the severity and mortality of COVID-19 and the safety of vaccines spread on social media, and affected citizens' attitudes and behaviors [11,15,42-47] (quotations 6 and 7). Participants were forced to devote significant resources to identifying and correcting misinformation [11,15] (quotations 8 and 9) but did not have effective measures to counter the sensational communication strategies used by purveyors of misinformation [11,39,43] (quotation 10). It was also more difficult to persuade people who had acquired a skeptical attitude through misinformation than it was to simply convey correct information [11,42,43,45].

Countering Misinformation

During the COVID-19 pandemic, participants learned several strategies to deal with misinformation. The first was the importance of timely communication; it was crucial that participants disseminated messages before misinformation spread [11,15,47] (quotation 11). Second, participants recognized that social listening improved their understanding of citizens' psychosocial aspects and information needs, as well as the quality of information they provided [11] (quotations 12 and 13). Third, participants had to recognize and address fear and anxiety among citizens [39] (quotation 14). Finally, participants recognized the importance of actively using social media to disseminate accurate information and guide people to reliable information sources [11,38,39,46,47] (quotation 15). However, the lack of human resources with expertise in using social media made it difficult to counter misinformation using these platforms [11] (quotation 16).

Difficulties in Partnerships Within and Outside Public Health

Tensions Within the Community of Public Health Experts

Participants recognized the importance of public health agencies partnering with epidemiologists, data scientists, sociologists, communication scholars, and other professionals with unique expertise for developing and implementing pandemic communication strategies [11,15,37,38,40,42,47-49]. This was because pandemic communication had to incorporate consideration of the social, economic, and political context that unfolded along with the health crisis [15,37,40,47-49] (quotation 17). However, there were coordination difficulties, especially in the early stages of the pandemic. Expert committees tended to be dominated by biomedical and virological researchers and often excluded sociologists and anthropologists [37] (quotation 18). A reason cited for the limited effectiveness of communication to citizens was that the strategies used lacked an understanding of people's sociocultural beliefs [38,49].

Tensions Between Public Health and Politics

The conflict of interest between health care and the economy was a major factor that characterized the communication difficulties during the COVID-19 pandemic [11,15,37-39,42,43,46,48,49] (quotation 19). The conflict between safeguarding public health and maintaining the economy abrogated the coherence of policy decisions and messages to the public and led to public confusion and distrust of public health [15,37-39,48]. This conflict of interest between health care and the economy also created tensions between public health professionals and political leaders who wanted to maintain their political popularity [37,48]. At the policy-making level, some political leaders did not accept or use the scientific evidence provided by public health experts [37,39,48,49]. Moreover, political leaders sometimes used and abused public health professionals to evade their own responsibilities in communicating with the public [37,46] (quotation 20). At the policy practice level, public health professionals were sometimes obstructed by political leaders from recommending preventive

XSL•FO
RenderX

behaviors and vaccination for citizens, rather than receiving political support [43,46] (quotations 21 and 22).

Difficulties in Coordination Between Public Health and Mass Media

Participants recognized the importance of close collaboration with the mass media [11,15,37,42,43,47]. They understood the influence of mass media in shaping public opinion and journalists' commitment to scientifically accurate and balanced reporting [15,37,47]. However, they recognized that during the COVID-19 pandemic, the mass media often engaged in misleading reporting, as well as pitting public health professionals against each other and politicians against public health professionals, quoting out of context, and linking public health professionals to specific political decisions [11,37,42,43]. In addition, some participants perceived that the biased discussion and criticism of public health activities in mass media coverage led to a decline in people's trust in public health [43] (quotations 23 and 24).

Difficulties in Community Engagement

Need to Tailor Communication to Community Realities

Some participants recognized that many of the COVID-19 recommendations were not consistent with community realities [45,50,51]. For example, small living quarters, large families, and essential travel by public transportation to buy food and work affected compliance with preventive behaviors such as social distancing [45,51]. Some citizens had to prioritize other essential living activities over infection prevention behaviors. For example, people of lower economic status had to go out to earn their living even during lockdown periods [45,51] (quotations 25 and 26). Compliance with COVID-19 prevention recommendations meant that many citizens faced economic hardship, food insecurity, domestic violence, and mental health problems [45].

Need to Consider Local Cultural Factors

Cultural factors such as a given community's dominant religion could also pose a barrier to compliance with the COVID-19 prevention recommendations [38,39,45,50] (quotations 27 and 28). However, participants recognized that cultural factors could act as both facilitators and inhibitors of public health activities [50]. They adapted their communication strategies to reflect community-specific sociocultural factors and incorporated ideas such as using culturally significant meeting places (eg, local religious centers) [45,50] (quotations 29 and 30).

Need for Bottom-Up and 2-Way Communication

Participants identified that the effectiveness of communication from health professionals to communities was inhibited by its 1-way nature [45,47,49,51] (quotation 31). Community groups and leaders were involved in implementing infection prevention programs; however, they had little involvement in planning and designing feasible programs [45]. Community participation tended to be lower when information was distributed from public health agencies to communities in a top-down manner. These top-down communication strategies, which lacked collaboration with the community, inhibited acceptance of recommendations for preventive behaviors [45,47,49]. This suggested that bottom-up and 2-way communication that involved the community were required to foster community engagement [45,47,49] (quotation 32).

Need to Build Trust With Communities

Participants generally responded that a trusting relationship between public health and the community was a factor in increasing community engagement [39,40,45,46,48,50,51]. They noted the importance of building trust with local political, religious, business, and agricultural leaders, along with schools, newspapers, radio stations, and other local organizations [40,48,50,51] (quotations 33 and 34). Existing local networks were especially important in developing grassroots communication activities [46] (quotation 35). In addition to trusting relationships with organizations, participants stated the importance of one-on-one trust relationships between health professionals and local residents [39,46] (quotation 36). However, in areas where public health outreach services had been reduced in the years before the pandemic, it was difficult to quickly rebuild trust between public health professionals and the community during the pandemic [50].

Need for Communication Through Community Channels

Communication through community-specific communication channels, such as local television and radio stations, social media platforms, and connections with trusted individuals, were emphasized as ways to increase community engagement [11,38,40,41,44-46,49-51] (quotation 37). Formal and informal communications were developed, including traditional media campaigns and disseminating messages via social media [11,40,41,45,50,51] (quotation 38). Participants noted that the key communication channels, including newspapers, radio, and social media, varied by community resident group [11,40,44,45,50,51] (quotation 39). For those groups using social media in particular, attempts were made to increase their engagement by encouraging their participation in communication activities [45,46] (quotation 40).

Difficulties in Effective Communication

Need for Uniformity and Promptness in Communication

Participants identified the absence of reliable sources of information known to citizens as an impediment to effective communication [11,15] (quotation 41). The plethora of available information sources, including mass media and social media, created confusion among citizens [11,15,43] (quotation 42). Furthermore, the importance of rapid information dissemination was crucial in communication regarding a hitherto unknown infectious disease [11,15,39,44,47] (quotations 43 and 44). However, participants faced a dilemma whereby prioritizing the speed of communication did not allow sufficient time to create effective messages. For example, translation into multiple languages was time-consuming [11,44] (quotations 45 and 46). In addition, it took time to crunch the vast amount of information and create concise, clear messages [11,44,45] (quotation 47).

Need for Understandable and Persuasive Communication

Participants emphasized the importance of efforts to ensure the public understood messages [11,37-40,42,45,48] (quotation 48).

XSL•FO
RenderX

These messages needed to have a clear purpose, use plain language and illustrations, and be persuasive to be easily understood and accepted by all citizens [11,38-40,45,48]. However, participants experienced difficulties in creating messages that addressed the various levels of citizens' individual health literacy [38,39,42,45] (quotation 49). Understandable communication was also important for politicians and policy makers who did not necessarily have basic scientific knowledge [37].

Need for Communication to Empower People

Participants noted the harms associated with health authorities generating stigma for certain populations [38-40]. For example, they accused young adults of often failing to follow recommendations for social distancing, and therefore, transmitting the virus, or of prolonging the pandemic by not being vaccinated [38,39] (quotation 50). They stressed that effective communication strategies should emphasize helping people make better informed decisions rather than punishing them with blame or fear or offering temporary reassurance [38,40] (quotations 51 and 52).

Burnout Among Communicators

Difficulties With Information Overload and Requests

Participants indicated that they felt like they were drowning in an overwhelming influx of information related to COVID-19 [11,41,51]. They tried to extract relevant information from this torrent; however, they did not know how to do so [51] (quotation 53). In addition, they were under intense pressure from the community to share the latest information about the novel virus [11,44] (quotation 54). Furthermore, public health professionals were expected to respond to constant media requests for updated information [11] (quotation 55).

Lack of Trust in Public Health

Participants experienced a lack of public trust, which led to communication difficulties [11,15,39,40,44,48,51]. A major contributing factor to this was discrepancies in the information disseminated by the government, municipalities, public health agencies, and professionals [15,39,48] (quotations 56 and 57). The confusion caused by these discrepancies increased people's distrust and decreased their willingness to accept infection prevention recommendations [15,40,44] (quotations 58 and 59).

Attacks on Public Health Professionals by Citizens

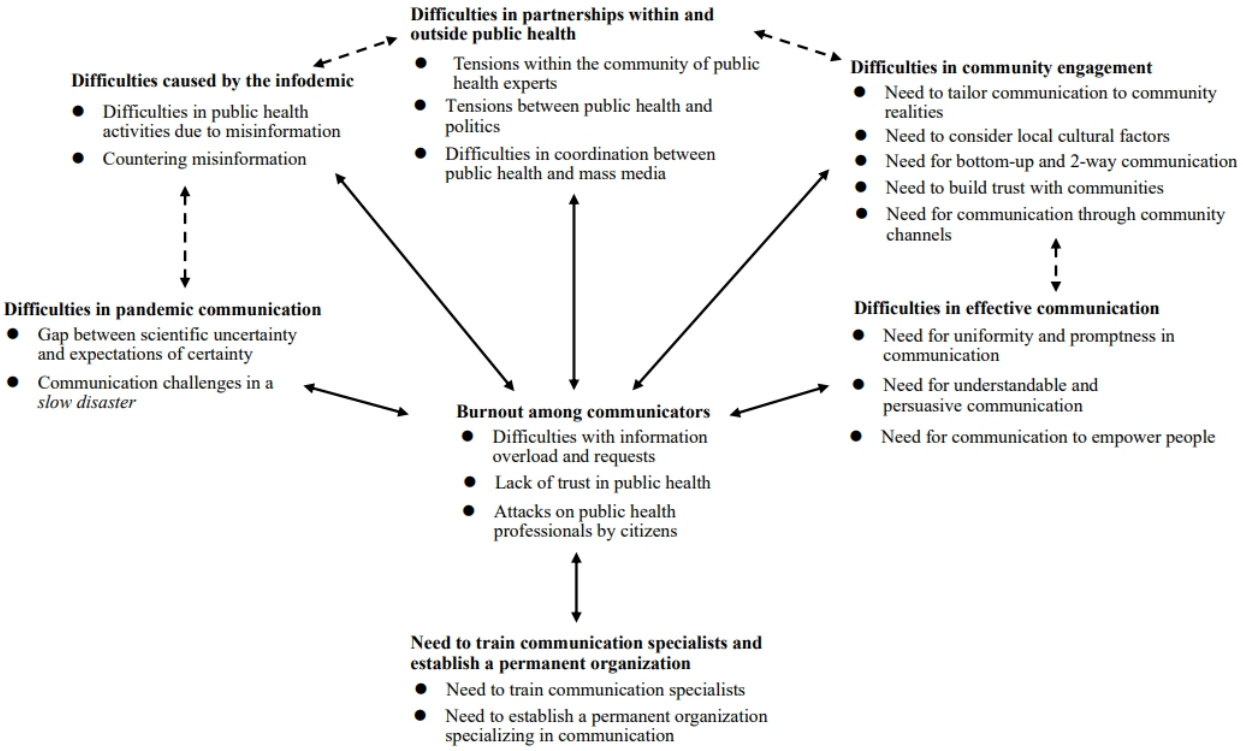
Participants experienced criticism and attacks from citizens despite their best efforts to overcome the aforementioned difficulties [11,37,43,44,46,48] (quotation 60). Daily criticism and attacks from citizens through social media, email, and community face-to-face meetings accelerated burnout among participants [11,43,44,46,48] (quotations 61 and 62). Accordingly, they sought ways to prevent burnout, including learning to set emotional boundaries for criticism [43] (quotation 63). They noted that rare words of gratitude from citizens empowered them [37,43] (quotation 64).

Need to Train Communication Specialists and Establish a Permanent Organization

Need to Train Communication Specialists

There was a notable lack of human resources with communication expertise during the COVID-19 pandemic [11,42,44,45,47]. In the early stages of the pandemic, public health agencies made efforts to increase the number of communications personnel by reorganizing their human resources [11]. However, securing a sufficient number of communications personnel, relative to the overwhelming volume of information that needed to be addressed, was difficult [11,42,45,47] (quotation 65). Personnel who had been moved to communications duties from other departments often lacked basic communication skills and competencies [11,42,45]. In addition, even those who had been previously trained in communications lacked the experience and ability to communicate effectively in the emergency pandemic situation [11,42] (quotation 66).

Need to Establish a Permanent Organization Specializing in Communication



Participants identified the rigidity within existing organizational structures as a problem. They emphasized that the many procedures, time-consuming approval processes, and inflexible and rigid protocols in the organizations inhibited rapid and effective public health communication [11,50]. They agreed on the importance of establishing a permanent organization specializing in public health communication [40,41] and noted that such an organization should train communication specialists, accumulate methods for effective communication strategies, build cross-functional partnerships with other organizations, and establish a structure to respond quickly in further public health crises [47] (quotation 67).

Conceptual Model

Figure 2 shows the conceptual model developed from the above results. Themes 3.2.1 to 3.2.5 were interrelated, and the difficulties experienced by communicators resulted in their burnout (theme 3.2.6). The difficulties and needs indicated in themes 3.2.1 to 3.2.6 indicated the need for future training of communication specialists and establishing a permanent organization specializing in communication (theme 3.2.7). It was assumed that training experts and establishing organizations would reduce difficulties and enable effective communication in subsequent public health crises.

Discussion

Principal Findings

This systematic review of qualitative studies examined the difficulties, challenges, and needs experienced by public health professionals during the COVID-19 pandemic and identified 7 themes. The theme of difficulties in pandemic communication encompassed difficulties stemming from scientific uncertainty and the "slow disaster." Public health crisis communication inherently involves uncertainty [52,53], and the WHO and the Centers for Disease Control and Prevention (CDC) recommended explicitly communicating information about uncertainties [1,54,55]. Researchers in crisis communication argued that communicating uncertainty increased rather than decreased public trust [56,57]. However, this systematic review revealed that risk communication in the real world is not as simple as the above recommendation suggests. Uncertainty reduction theory indicates that humans are intrinsically motivated to reduce uncertainty [58]. Therefore, communicating uncertainty creates a conflict with people's demand for certainty. However, when people's trust in their government and communicators is stronger, they tend to more successfully accept uncertainty [59]. People's trust in government and public health agencies may offer a clue to resolving communication difficulties associated with uncertainty. Furthermore, neither the WHO nor CDC guidelines contained details on how to deal with communication difficulties stemming from a slow disaster [1,54,55]. Coping with pandemic fatigue was one of the difficulties stemming from the slow disaster. Although previous studies have examined factors associated with pandemic fatigue during the COVID-19 pandemic [60,61], much remains unknown about pandemic fatigue. Further research should consider effective communication strategies for a slow disaster.

The communication difficulties in the COVID-19 pandemic were characterized by the destructive impact of the infodemic. A survey conducted in the United Kingdom in 2020 showed that 46% of the public had been exposed to fake news about COVID-19 and 40% said they could not tell the difference between truth and lies [62]. Previous studies have examined effective debunking methods for misinformation [18-21]. The CDC also developed public health infodemic surveillance systems in the wake of the COVID-19 pandemic [63]. Furthermore, there are more than 100 laws against disseminating misinformation in different countries worldwide [64]. A multifaceted approach is needed to prepare for future public health infodemics, including surveillance, communication, and legal regulation.

The WHO guidelines to address COVID-19 emphasized the importance of collaboration within public health agencies and with external partners [55]. However, this systematic review found that, in reality, tensions in and outside of public health agencies hindered an effective crisis response. During noncrisis periods, governments, public health agencies, researchers, and media are often siloed, making crisis-related coordination and information sharing difficult [65]. In addition, political and economic interests that conflict with public health policies hinder an effective pandemic response [66]. Such partnership failures, which were experienced in past epidemics and pandemics, were repeated in the COVID-19 pandemic. Addressing this is a crucial challenge going forward.

Existing public health organization guidelines emphasized the importance of community engagement strategies [1,54,55].

XSL•FO
RenderX

Many studies have shown that community-based cultural factors were related to preventive behaviors and mortality rates during the COVID-19 pandemic [67-70]. Furthermore, language and cultural barriers prevented access to information, understanding of messages, and compliance with recommendations during the pandemic [71,72]. This systematic review showed that top-down, 1-way communication to the community hindered effective pandemic responses, despite the importance of a bottom-up approach that involves community stakeholders and residents in decision-making having been officially emphasized [73]. Communication in public health crises requires adapting communication strategies to the cultural, social, and demographic background of the local community to gain support among the target population [74]. To achieve this, it is important to break away from top-down, 1-way communication and adopt a 2-way, bottom-up approach that includes dialogue with the community [75].

During epidemics and pandemics, it is important that information from public health agencies is not overtaken by competing misinformation [25]. The first message that an audience receives shapes their subsequent attitudes [76]. Therefore, quick dissemination of information based on partial evidence is better than delayed dissemination of information based on complete evidence [1,55,77] because prompt communication is an essential principle of risk communication [54]. However, this systematic review revealed that the speed of communication hindered the effectiveness of communication during the COVID-19 pandemic. Public health professionals experienced difficulty in securing time for translation, pretesting, and creating easy-to-understand messages as they were under pressure to communicate quickly. The COVID-19 pandemic highlighted the difficulty of following existing crisis communication guidelines in a real-world crisis response.

Many public health professionals experienced burnout during the course of the pandemic. The main factors contributing to burnout were information overload that exceeded limited human resources, along with criticism and attacks on public health professionals from the public. The lack of public trust in public health also contributed to attacks against health professionals. The degree of trust in public institutions was associated with the rate of COVID-19 infection and the associated mortality rate [78]. A 2022 report by the Organisation for Economic Co-operation and Development highlighted that public trust was a key insight from the evaluation of responses to the pandemic, which pointed to the importance of building trust over a long period before a crisis occurs [73]. Building public trust and preventing burnout among public health professionals are essential for preparing for future public health crises.

The aforementioned 6 themes suggested the seventh theme, the need to train communication specialists and establish permanent organizations specializing in communication. These measures are necessary to address the aforementioned issues brought to light by the COVID-19 pandemic. COVID-19 showed that many countries had failed to learn the lessons of past global infections (eg, severe acute respiratory syndrome and influenza A virus subtype) and had failed to prepare for a future public health crisis [73,79]. Even now, many countries are still not prepared for future public health crises [80]. Another public health crisis occurring is not a matter of "if" but of "when" [81]. The best way to manage a crisis is to prevent one [25], and the second-best way to manage a crisis is to prepare for one [82]. All public health institutions and professionals must learn from the difficulties, challenges, and needs identified in this systematic review and update their strategies and guidelines to implement more effective communication in the next public health crisis.

Future Directions for Practitioners

The results of this systematic review suggest the following practice implications, which may help to prepare for the next public health crisis. (1) The scientific process is accompanied by uncertainty; however, politicians and citizens seek certainty. It is necessary to increase trust in public health organizations and address the communication difficulties associated with uncertainty, to address pandemic fatigue, and to develop effective communication strategies for future slow-onset disasters. (2) More research and practice are needed to manage misinformation in public health crises, including surveillance and communication strategies for "prebunking" and debunking information. (3) Partnerships between stakeholders at both the policy-making and communication practice levels are needed to manage public health crises. Such partnerships are important for enabling the creation and transmission of consistent messages, and avoiding confusion among citizens and distrust in public health. (4) It is necessary to build trusting relationships between public health organizations and communities before a crisis occurs and to enable bottom-up communication during crises. (5) It is also necessary to address the trade-off between communication promptness and effectiveness and conduct communication with the aim of empowerment. (6) Measures are needed to prevent burnout among health professionals during a crisis. (7) To address these issues and support an effective response to future public health crises, it is necessary to train more communications specialists, establish permanent organizations specializing in communication, and update strategies and guidelines.

Limitations

This systematic review had several limitations. First, we conducted a rigorous literature search and qualitative synthesis with 2 or more reviewers. However, we could not completely rule out the possibility that some relevant literature had not been included. Second, we did not weight the interpretation of study results according to the quality appraisal of the included studies; however, the included studies showed an overall good methodological quality. Third, because this was a systematic review of previous studies, our interpretations were limited by the data that were reported in the included studies. Fourth, participants in the included studies had various occupational backgrounds such as policy makers, officials in local municipalities, frontline health care workers, and scientists. A strength of this review was that it reflected the experiences of participants from diverse backgrounds; however, it was also limited by not differentiating experiences at the policy-making level from those at the policy implementation level on the front line. Fifth, another strength was that we included studies from various countries in Europe, the Middle East, Asia, Africa, and

XSL•FO
RenderX

North and South America; however, a limitation was that we did not make any economic or cultural distinctions. Finally, because all crises are novel and involve contextual differences, the generalizability of the findings and implications of this study to future crises is limited. Despite these limitations, this review has the important implications mentioned earlier, in that it identified the gaps between existing crisis communication guidelines and real-world crisis communication and the difficulties and needs that arise from those gaps.

Conclusions

This systematic review of qualitative studies identified the following issues that need to be addressed to prepare for subsequent public health crises. Despite the importance of collaboration within and outside public health and community engagement being highlighted in existing crisis communication guidelines, there was insufficient preparation and response to the COVID-19 pandemic. Although prompt communication is an essential principle for crisis response, the trade-off between promptness and the effectiveness of communication should be addressed. Difficulties specific to “slow disasters” and “infodemics” characterized the challenges encountered during the COVID-19 pandemic. Information overload, a shortage of human resources, and a lack of trust in public health contributed to burnout among health professionals. Public health professionals need to address the difficulties and needs identified in this systematic review by training communication specialists and establishing permanent organizations specializing in communication. One health professional described the difficulties resulting from the lack of preparation during the COVID-19 pandemic as “we are building the plane while we are flying” [44]. Of course, airplanes must be built before they fly, and in the case of a public health crisis, preparations must be made before the crisis arises.

Abstract

Background: Hypertrophic scars (HTSs) are a predominant condition after burns and trauma, and it causes severe physiological and psychological problems. TikTok (Douyin in Chinese), a popular platform for sharing short videos, has shown the potential to spread health information, including information related to HTSs. Educating the public to obtain correct information is important to reduce the incidence of physiological and psychological problems caused by HTSs. However, the quality and reliability of HTS-related video content on TikTok in mainland China have not been thoroughly studied.

Objective: This study aims to evaluate the content and quality of short videos related to HTSs on the Chinese version of TikTok (Douyin) and explore the factors related to their quality, providing valuable insights for health information dissemination.

Methods: We collected a sample of 153 TikTok videos in Chinese related to HTSs and categorized them according to video source and content. We evaluated the video content using a coding schema, and a hexagonal radar schema was used to intuitively display the spotlight and weight of each aspect of the videos. We evaluated quality using 4 standardized tools: the modified DISCERN (mDISCERN) questionnaire, the *Journal of the American Medical Association*, the Global Quality Scale (GQS), and the Health on the Net Foundation Code of Conduct. We also explored the potential relationship between video quality and characteristics.

Results: The analysis showed that health care professionals uploaded all videos about treating HTSs, which matched the hexagonal radar model analysis findings. The quality assessment scores for the *Journal of the American Medical Association*, GQS, mDISCERN, and the Health on the Net Foundation Code of Conduct had median values of 1 (IQR 1-2), 2 (IQR 2-3), 2 (IQR 2-3), and 3 (IQR 3-4), respectively, indicating a need to improve the quality and reliability of videos on HTSs. In addition, high-quality videos were more popular, based on metrics such as likes, comments, favorites, and shares (P<.001). Interestingly, the time when the videos were uploaded positively correlated with GQS and mDISCERN scores (r=0.393; P<.001 and r=0.273; P<.001), while the video length did not significantly correlate with evaluation scores (P=.78, P=.20, P=.07, and P=.04).

Conclusions: The quality of TikTok videos related to HTSs is generally moderate. Users should exercise caution when seeking information on HTSs from TikTok. It is advisable to choose videos uploaded by health care professionals from the burn department and the burn plastic surgery department, and in the Chinese context, those produced in first-tier cities and emerging first-tier cities.

Introduction

Background

Hypertrophic scars (HTSs) are a common fibrotic skin condition that can develop from various sources, including acute or chronic wounds, deep burns, and surgical incisions [1]. The overall incidence of HTSs ranges from 4% to 16%, but among patients with burns, the prevalence can be as high as 70% [1,2]. A study of Chinese college students reported an incidence rate of HTSs at 5.2% [3]. In high-income countries, around 100 million individuals are affected by HTSs [4]. HTSs can negatively impact a person's appearance and lead to impaired skin function, joint deformities, and decreased mobility, significantly affecting mental and physical well-being [5]. The annual global cost for HTS care is estimated at nearly US $20.8 billion, with the United States spending about US $4 billion on treatment yearly [6]. The market for HTS and keloid scar treatments is projected to grow, potentially reaching US $37.9 billion by 2026, with a compound annual growth rate of 9.9% [7]. Making lifestyle changes, such as minimizing intense physical labor, avoiding spicy foods, reducing alcohol consumption, and limiting time spent in hot baths, may help lower the risk of developing HTSs [2]. Early detection, diagnosis, and effective treatment are essential for improving patient outcomes and addressing the physiological and psychological issues related to HTSs. Therefore, educating the public about accurate and reliable health information is crucial in reducing the incidence of problems associated with HTSs.

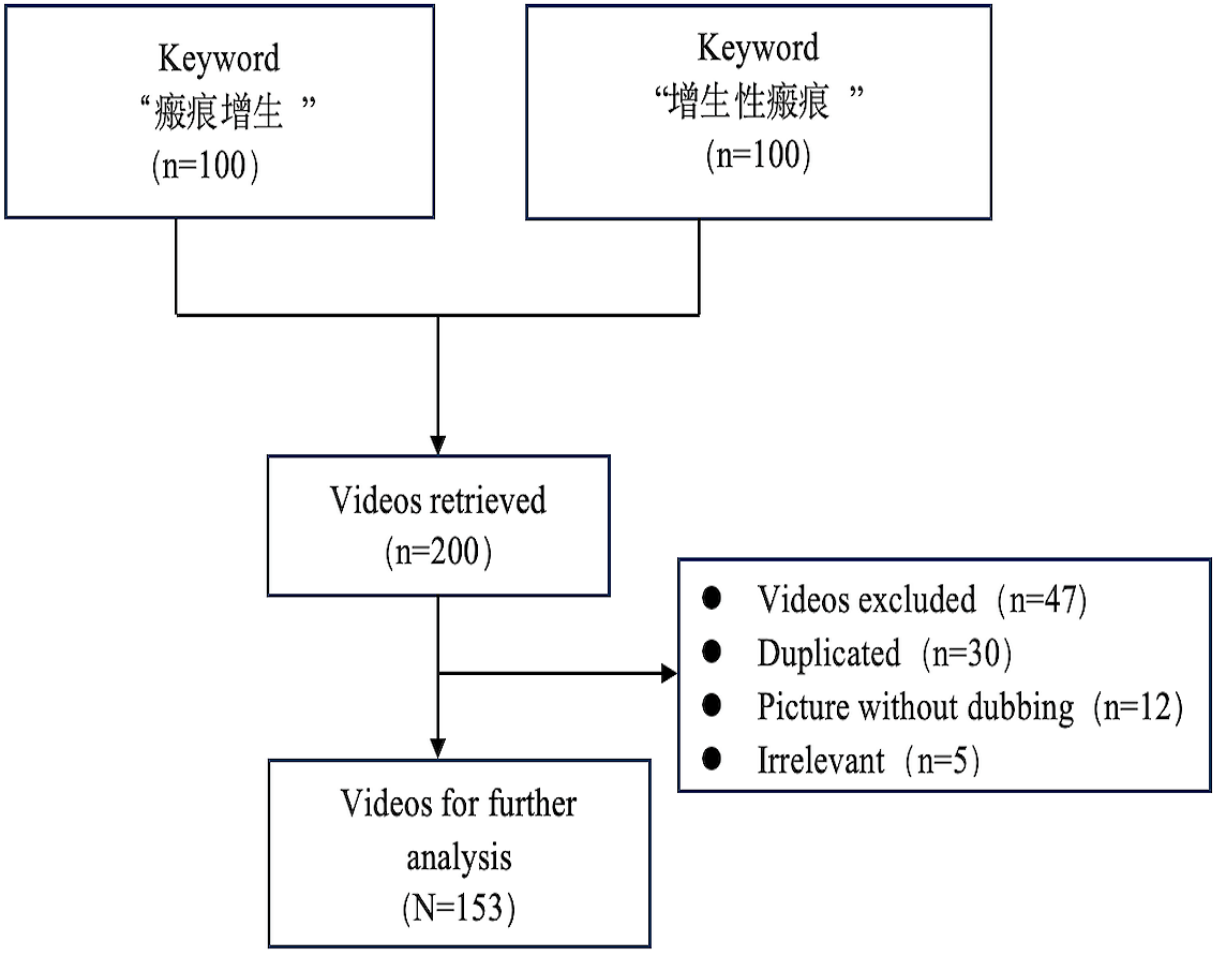
Health Information in the Digital Era

The rapid advancement of internet technology has transformed how we share and communicate health information [8,9]. Remarkably, around 80% of individuals worldwide rely on online resources to inform themselves about health matters [10,11]. This shift enhances health communication and unprecedentedly empowers patients in their education and decision-making [12]. With easy access to information online, patients are no longer passive recipients; they have become proactive seekers, fully engaged in their health outcomes [13]. In recent years, health education videos designed to inform viewers, individually or collectively, have surged in popularity [14]. Unlike traditional text, videos on social media platforms present information more digestibly and effectively motivate users toward healthier behaviors through compelling visuals [15,16]. Short video platforms have the potential to spread health education widely, but patients may encounter challenges in using these technologies. Patients' primary concern when searching for online health information is the quality of the information [17]. The rise of numerous content creators and the lack of regulation on these platforms often lead to concerns about the trustworthiness of the medical information shared [18]. When searching for online health information, the quality of the information is a primary concern for patients [17]. For many nonprofessionals, evaluating the quality of online health information sources, especially for patients with lower health literacy levels, is not easy [19]. Due to the varying quality of short video content, patients often struggle to distinguish between true and false information. This can lead to the spread of misleading information, potentially impacting patients' understanding of their own medical conditions [20]. It is important to recognize that the content creators on video platforms could be (1) patients themselves or (2) health professionals. Experience sharing by patients who have experienced similar conditions can be a handy educational mechanism for other patients or their caregivers [21]. Health professionals, experts in their fields, can also offer helpful advice. However, more must be done to verify the authenticity of the sources (patients or health professionals) producing these videos. This is one of the primary reasons why a lot of misinformation or unverified health information is propagated on social media and video platforms. Therefore, establishing robust oversight of online health videos is crucial to ensure that patients receive reliable and accurate health information.

This Study

TikTok (ByteDance), or Douyin, its Chinese name, is the leading video social media app in China, captivating a vast audience. Focusing on diverse content, such as food, travel, and education, it has attracted over 750 million daily active users, making it a vital platform for engagement and discovery [22]. During the COVID-19 pandemic, TikTok videos about the SARS-CoV-2 garnered 93.1 billion views by July 2020 [17,19]. In addition, videos tagged with #cancer have amassed over 1.1 billion views worldwide [23]. As a platform for disseminating health information, social media has significant differences in video quality and information accuracy. Previous studies have shown that videos published by health care professionals typically have higher scientific validity and credibility [24]. However, the popularity of these videos is often limited by the social influence of the publishers. Videos posted by social media influencers with many followers may attract more viewers and interactions, even if they lack professionalism. In addition, Ming et al [25] found that erroneous information is commonly present in health education videos released by for-profit organizations. This further highlights the necessity of evaluating video quality and authenticity. Previous research has examined the quality of videos on various themes on TikTok, revealing differences in video quality. For instance, videos about *Helicobacter pylori* infection [11], breast cancer [26], liver cancer [20], and inflammatory bowel disease [27] are generally considered unsatisfactory in quality. In contrast, videos related to plastic surgery are deemed satisfactory in quality and reliability [28]. We found many videos about HTSs on Douyin, the Chinese version of TikTok, but the quality of the information presented is yet to be evaluated. To address this research gap, we assessed the content, quality, and reliability of HTS-related videos on TikTok. We examined the relationship between the quality of video content and audience engagement, focusing specifically on interactive indicators, such as likes, comments, favorites, and shares.

Methods



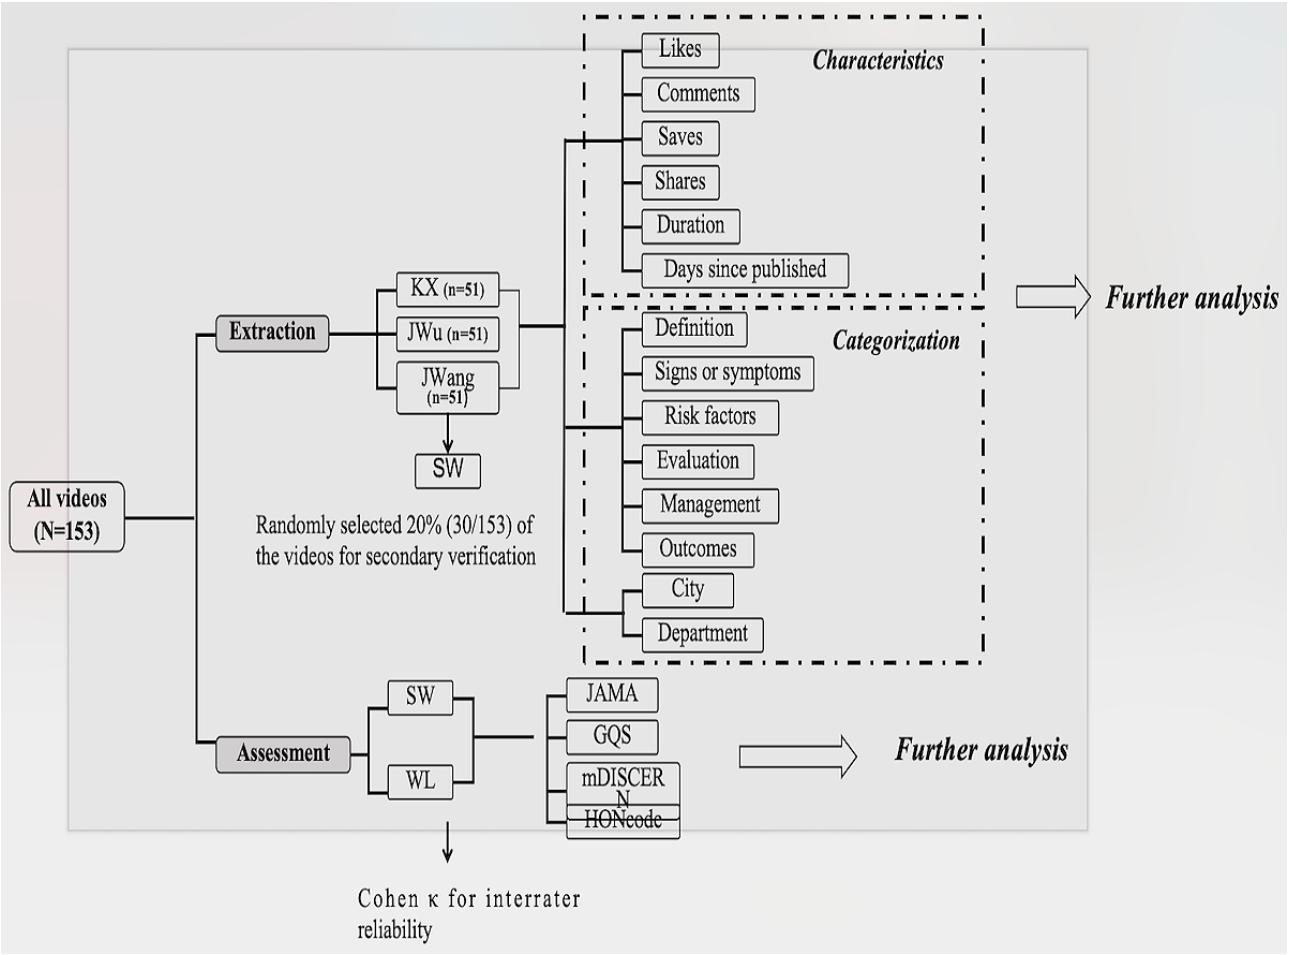
Search Strategy and Data Extraction

In this cross-sectional study, we used the keywords "瘢痕增生" ("scar hyperplasia" in Chinese) and "增生性瘢痕" ("hypertrophic scars" in Chinese) to search on the Chinese version of TikTok ("Douyin") on February 28, 2024, with the

XSL•FO
RenderX

default sorting option of "overall ranking." To avoid bias caused by personalized recommendations, we used newly registered accounts to conduct searches. We did not apply any filtering conditions to restrict the search. Consumers seeking general health videos typically do not scroll very far when searching online; they usually browse only the first few pages of search results. Furthermore, videos that rank low in the search results of the "overall ranking" mode often have little relevance to the topic [29]. Considering the aforementioned situation, we selected the top 100 videos for further analysis of the search results. Subsequently, we excluded non-Chinese, irrelevant, repetitive, and silent videos, resulting in 153 videos selected for the final data analysis (Figure 1).

Figure 1. Search strategy for short videos on hypertrophic scars.



Exclusion criteria were non-Chinese videos and repetitive videos—which refers to videos with the same content but different sources; we based our judgments on the video descriptions and main content. We excluded silent videos, which are defined as content that consists only of images or text, with no voice or background sound. We determined whether a video was silent by overseeing each clip to ensure no audio. Moreover, we excluded irrelevant videos, which refers to videos that do not pertain to the themes of "scar hyperplasia" or "hypertrophic scars." Examples included advertisements, entertainment videos, or content related to other health topics. We based our judgments on the video descriptions and main content.

We extracted data directly from the public information provided by the TikTok platform, as it lacks a bulk data export function. Consequently, we manually recorded the relevant data for each video. Team members used browser tools, including screenshots and text-copying functions, to transfer video information into Microsoft Excel spreadsheets for further classification and analysis. Three team members (J Wu, KX, and J Wang) completed the data extraction, each responsible for a specific portion of the videos. To ensure the accuracy of the data entry, we developed a unified operations manual, and cross-checking was conducted by another team member (SW) after the data entry was finished. In addition, we randomly selected 20% (30/153) of the videos for secondary verification, which resulted in a data consistency rate of over 95% (Figure 2).

XSL•FO
RenderX

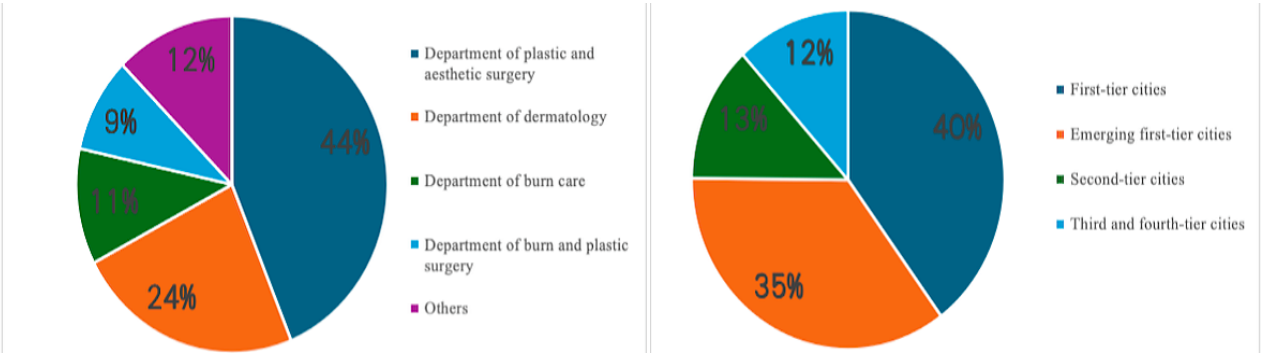


Figure 2. Flowchart for data extraction and analysis. GQS: Global Quality Scale; HONcode: Health on the Net Foundation Code of Conduct; *JAMA*: *Journal of the American Medical Association*; mDISCERN: modified DISCERN.

Video Classification

The content of the videos was classified through manual review. Three authors (J Wu, KX, and J Wang) independently watched each video and categorized it into 1 of the following 6 groups based on its content: the definition, signs and symptoms, risk factors, evaluation, management, or outcomes. All videos were provided by health care professionals; we further classified them according to department categories, specifically including plastic and aesthetic surgery, dermatology, burn care, burn and plastic surgery, and a general category termed "other departments," which includes various departments, such as traditional Chinese medicine and pediatric surgery. In addition, to comprehensively consider the distribution of video resources, we categorized the videos based on city administrative levels, including first-tier cities, emerging first-tier cities, second-tier cities, third-tier cities, and fourth-tier cities, to reflect regional differences more accurately (Figures 2 and 3, Tables 1 and 2) [30].

Figure 3. Percentage of videos on health care professionals from different departments and city tiers.

Table 1. Scoring criteria and weight for categorization of cities.

Scoring criteria	Weight
Commercial resource concentration	0.19
Big Brand Favorability Index	0.32
Commercial Core Index	0.40
Commercial support maturity	0.28
Urban hub connectivity	0.2
Transportation connectivity	0.33
Talent Mobility Index	0.27
Industry Synergy Index	0.20
Commercial resource regional centrality	0.2
Urban population activity	0.22
Consumption activity	0.38
Social activity	0.31
Nighttime activity	0.31
New economy competitiveness	0.20
Corporate leadership	0.36
New Consumption Index	0.32
Industry Chain Ecosystem Index	0.32
Future flexibility	0.19
Innovation Atmosphere Index	0.32
Talent Attraction Index	0.39
City Size Index	0.29

Table 2. The 2024 China city classification rankings.

City classification	List of cities
First-tier cities	Shanghai, Beijing, Shenzhen, and Guangzhou
Emerging first-tier cities	Chengdu, Hangzhou, Chongqing, Suzhou, Wuhan, Xi'an, Nanjing, Changsha, Tianjin, Zhengzhou, Dongguan, Wuxi, Ningbo, Qingdao, and Hefei
Second-tier cities	Foshan, Shenyang, Kunming, Jinan, Xiamen, Fuzhou, Wenzhou, Changzhou, Dalian, Shijiazhuang, Nanning, Harbin, Jinhua, Nanchang, Changchun, Nantong, Quanzhou, Guiyang, Jiaxing, Taiyuan, etc.
Third-tier cities	Urumqi, Linyi, Haikou, Huzhou, Yangzhou, Yancheng, Luoyang, Tangshan, Jining, Langfang, Taizhou, Ganzhou, Hohhot, Zhenjiang, Wuhu, Shantou, Handan, Jiangmen, Zibo, Yinchuan, etc.
Fourth-tier cities	Zhoushan, Qingyuan, Quzhou, Zhumadian, Deyang, Yibin, Longyan, Rizhao, Hongzhi, Anshan, Maoming, Binzhou, Qinhuangdao, Jilin, Kaifeng, etc.

The weights of the primary and secondary dimensions of the ranking were determined through scoring by the expert committee of the New First-Tier Cities Research Institute, while the indicators mentioned after the secondary dimensions were calculated using the principal component analysis method. The indicators for each subdimension of the ranking were primarily derived from data collected throughout 2023 or up to early 2024.

In this study, to determine the geographic location of video creators, we mainly obtained relevant information through 2 channels. First channel was user profile information, where the TikTok account profile of the video uploader usually voluntarily disclosed location information, such as city name or workplace. We manually checked the account home page of each uploader and recorded the geographic location mentioned in their profile (such as a hospital in Beijing). The second channel was the certification identification and employer information, where the TikTok platform usually included the publisher's employer and department information for certified accounts. For example, the authentication information may have included "burn and plastic surgery department of a hospital in Shanghai" or "dermatology department of a hospital in Guangzhou," based on which we could determine the geographic location of the uploader.

XSL•FO
RenderX

Assessment of Video Content, Quality, and Reliability

We used the 6 questions developed by Goobie et al [31] to assess video content, focusing on disease definition, signs and symptoms, risk factors, evaluation, management, and outcomes. The hexagonal radar chart is a unique statistical tool that can display data from 6 different fields at the same time. Each dataset is mapped onto a separate axis, and the data points on each axis are connected by continuous lines to form a hexagonal outline. The main goal of this chart design is to visually represent the focus and impact weight of a specific subject, such as video content, across 6 core dimensions [19]. By doing so, the hexagonal radar chart simplifies the comprehension of complex data and provides a clear and user-friendly visual representation for both users and researchers [12,32].

The videos' reliability and quality were assessed using 4 standardized evaluation tools: modified DISCERN (mDISCERN; Table 3), Global Quality Scale (GQS; Table 4), the *Journal of the American Medical Association* (*JAMA*; Table 5), and the Health on the Net Foundation Code of Conduct (HONcode; Table 6). We used a multifaceted approach to assess the quality and reliability of the educational content of the videos collected, mainly based on the following considerations:

- Each benchmark focuses on different dimensions. mDISCERN assesses the information quality, GQS evaluates overall content quality, *JAMA* evaluates the reliability of the video, and the HONcode examines the ethics and credibility of health information.
- By integrating multiple benchmarks, it is possible to more comprehensively capture the differences in quality and reliability dimensions in short videos.
- The multibenchmark method improves the objectivity of evaluation and avoids bias that may arise from a single benchmark.

Table 3. Description of modified DISCERN (mDISCERN) for evaluating the quality of the videos with information on hypertrophic scars.

mDISCERN	Scores (1 point is given for every yes and 0 points for no)
Is the video clear, concise, and understandable?	0-1
Are reliable sources of information used? (ie, publication cited and speaker is a specialist)	0-1
Is the information presented balanced and unbiased?	0-1
Are additional sources of information listed for patient reference?	0-1
Are areas of uncertainty or controversy mentioned?	0-1

Table 4. Description of the Global Quality Scale (GQS) for evaluating the quality of the videos with hypertrophic scars information.

GQS	Scores (range from 1=poor quality to 5=excellent flow and quality)
The information is of poor quality, and the flow of the site is poor. Most information is missing and not useful for patients at all.	1
The information is generally of poor quality and flow. Some information is listed, but many important topics are missing, and it is of very limited use to patients.	2
Moderate quality and suboptimal flow: Some vital information is adequately discussed, but other topics are poorly discussed and somewhat useful for patients.	3
Good quality and flow: Most relevant information is listed, but some topics still need to be covered. It is useful for patients.	4
The information is of excellent quality and has excellent flow. It is beneficial for patients.	5

Table 5. Description of the *Journal of the American Medical Association (JAMA)* for evaluating the quality of the videos with hypertrophic scar information.

JAMA benchmark criteria	1 point for each criterion, with a total score of 4 points
Authorship	Author and contributor credentials and their affiliations should be provided.
Attribution	All copyright information should be clearly listed, and references and sources for content should be stated.
Currency	The initial date of posted content and subsequent updates to the content should be provided.
Disclosure	Conflicts of interest, funding, sponsorship, advertising, support, and video ownership should be fully disclosed.

XSL•FO
RenderX

Table 6. Description of the Health on the Net Foundation Code of Conduct (HONcode) for evaluating the quality of videos with information about hypertrophic scars.

HONcode	Detail
Authority	Any medical or health advice given in the video must come from a qualified health professional unless it is clearly stated that the information does not come from a qualified health source.
Complementarity	The information provided in the video must be designed to support the patient's HTS[a] self-management, but it is not meant to replace the patient-physician relationship.
Privacy policy	The information in the video maintains the right to confidentiality and respect of the individual patient featured.
Referenced and dated	Each video contains references to source data on information presented or contains a specific HTML link to source information.
Justifiability	Each video containing claims on the benefits or performance of specific skills and behaviors, interventions, treatments, products, etc must be supported by evidence through references or HTML links.
Transparency	The video must provide the viewer with contact information or a URL to more information.
Financial disclosure	Any individual or organization that contributes funds, services, or material in the posted video must be clearly identified in the video or video description.
Advertising policy	If an advertisement supports funding to the video or the video's developers, it must be clearly stated. Included advertising must be clearly differentiable to the viewer. There should be a clear difference between the advertising material and the educational material in the video.

[a]HTS: hypertrophic scar.

mDISCERN is the most commonly used quality research tool [33]. This method has been widely used to evaluate information quality on video-sharing platforms [34]. Considering that the video studied belongs to the medical category, mDISCERN is based on the following 5 aspects: clarity, relevance, traceability, robustness, and fairness. The mDISCERN has 5 questions that need answers as "yes" or "no." A score of 1 indicates yes, 0 indicates no, and the maximum score is 5 [35].

GQS was used to assess the overall content quality of the videos in this study. The GQS is a commonly used 5-point scale comprising 5 criteria ranging from 1 to 5, with higher scores indicating better quality [36-38].

JAMA was used to evaluate the reliability of the video [39]. The rating is according to the 4 predetermined issues: authorship, attribution, currency, and disclosure. There is 1 point for each criterion, with a total score of 4 points [40].

The HONcode consists of 8 issues that are predetermined for the rating: authority, complementarity, privacy policy, reference and date, justifiability, transparency, financial disclosure, and advertising policy [41,42]. The details of the scoring criteria are mentioned subsequently. First, any medical or health advice given in the video must come from a qualified health professional unless it is clearly stated that the information does not come from a qualified health source. Second, the information provided in the video must be designed to support the patient's HTS self-management, but it is not meant to replace the patient-physician relationship. Third, the information in the video maintains the right to confidentiality and respect of the individual patient featured. Fourth, each video contains references to source data on the information presented or contains a specific HTML link to source information. Fifth, each video containing claims on the benefits or performance of specific skills or behaviors, interventions, treatments, products, etc must be supported by evidence through references or HTML links. Sixth, the video must provide the viewer with contact information or a URL to more information. Seventh, any individual or organization that contributes funds, services, or material in the posted video must be clearly identified in the video or video description. Eighth, if an advertisement supports funding to the video or the video's developers, it must be clearly stated. Included advertising must be differentiable to the viewer: There should be a clear difference between the advertising material and the educational material in the video. There is 1 point for each criterion, with a total score of 8 points.

Although *JAMA* and HONcode are commonly used to evaluate formal or long-format medical content (such as websites, journals, or organizational publications), their application has been extended to user-generated content on the TikTok short video platform [43]. In this study, we had a detailed discussion on the benchmark before scoring and adjusted the scope of application of the scoring criteria. For the "disclosure" rating item, we focused on whether the video identified the publisher's identity and affiliation rather than detailing funding sources or advertising disclosures. Regarding the "citation source" standard, many videos did not provide explicit references and often used vague terms, such as "research shows" or "experts say." To tackle this issue, we reached the following consensus: (1) videos that do not provide any source explanation will receive a score of 0; (2) content that mentions vague references (like "research shows") but fails to specify the source will receive a score of 0.5, indicating a partially satisfied score; and (3) videos that list their sources or include relevant reference information in the video description will receive a score of 1. We also focused on evaluating whether the core medical information of the video was accurately conveyed based on the video duration limit rather than comprehensive coverage. In addition, during the rating process, we considered the background information of the video creator (such as certification marks or institutional affiliations) to help evaluate the credibility of the references.

The videos were evaluated by 2 qualified physicians (SW and WL) who have extensive experience in scar treatment. Before scoring the videos, the 2 evaluators reviewed the mDISCERN,

XSL•FO
RenderX

GQS, *JAMA*, and HONcode scoring guidelines and conducted detailed discussions to prevent cognitive bias. The final score for each video was calculated by averaging the scores given by the 2 evaluators. If there was a significant difference between the scores of the 2 experts, the final score was determined through discussion with the third arbitrator (KX; Figure 2). In the evaluation process of 153 videos, Cohen κ values rated by experts showed high consistency (κ>0.80). Therefore, no case involved the third arbitrator.

Ethical Considerations

All information used in this study came from publicly published TikTok (Douyin in Chinese) videos. This study did not involve clinical data, human specimens, or animal experiments, nor did it involve personal privacy. No personal data identifying the uploader's identity, such as username or profile picture, were recorded or stored during the research process. Data analysis only focused on video content and interaction metrics (such as likes, comments, and shares). The study strictly abided by the terms of use of the TikTok platform and did not obtain the platform's undisclosed data through any technical means. The research content did not involve any potential harm to user interests or platform rules and was only used for academic purposes. Therefore, this study did not require an ethics review.

Statistical Analyses

The data were analyzed using SPSS Statistics (version 29; IBM Corp). Continuous variables were presented as medians with IQRs, while categorical variables were presented in terms of numbers and percentages. Cohen κ was used to measure interrater reliability between the 2 evaluators. According to the criteria set by Landis and Koch [44], a κ value > 0.8 indicates almost perfect agreement, a value between 0.6 and 0.8 indicates substantial agreement, a value between 0.4 and 0.6 indicates moderate agreement, and a value <0.4 indicates poor agreement. Spearman correlation analysis was conducted to assess the relationships between quantitative variables. A significance level of $P<.001$ was considered statistically significant.

Results

Video Characteristics

A total of 153 videos about scar hyperplasia and HTSs were found on Chinese TikTok, all posted by health care professionals. In terms of departmental distribution of video uploads, professionals from the department of plastic and aesthetic surgery contributed the highest proportion of video content, accounting for 67 videos (43.8%), followed by dermatology (n=36, 23.5%), burn care (n=17, 11.1%), burn and reconstructive surgery (n=14, 9.2%), and "other departments," which included traditional Chinese medicine and pediatric surgery (n=19, 12.4%). Further analysis by city tier revealed significant differences in video publication volume. Health care professionals in first-tier cities were the most active, accounting for 61 (39.9%) of the video uploads, followed by new first-tier cities (n=54, 35.3%), second-tier cities (n=20, 13.1%), and third- and fourth-tier cities (n=18, 11.8%; Figure 3). The general characteristics of the videos are presented in Tables 7-9.

The median time since upload was 212 (IQR 54-321) days, and the average video duration was 43 (IQR 33-58, SD 36) seconds. All videos received a maximum of 21,000 likes (median 72, IQR 31-189), 1230 comments (median 9, IQR 4-32), 7580 favorites (median 21, IQR 7-66), and 2292 shares (median 20, IQR 9-63). Table 8 describes the critical features of the videos uploaded by health care professionals from different departments. Notably, videos posted by dermatologists stood out in several engagement metrics, specifically with higher numbers of likes (median 112.5, IQR 44.5-254), comments (median 12, IQR 5.75-46.25), saves (median 36.5, IQR 13.75-94.75), and shares (median 29, IQR 11.75-70.75). This phenomenon may reflect the public's interest and preference for educational dermatology videos. Further analysis (Table 9), which focused on the essential characteristics of videos uploaded by health care professionals from different city tiers, revealed a notable phenomenon. Although some cities may not have the overall resource advantage, emerging first-tier cities' videos showed unique appeal in user engagement. The median numbers of likes, comments, saves, and shares were 94 (IQR 37.75-183), 12 (IQR 5-55.5), 24.5 (IQR 8-78.75), and 26.5 (IQR 10.25-66), respectively. This finding suggested that video content dissemination strategies should focus more on regional characteristics and alignment with user needs. In addition, the shortest video was 13 seconds long, the longest was 282 seconds long, and the first video was uploaded 1047 days before our search. In contrast, the most recent video was uploaded the day before data collection.

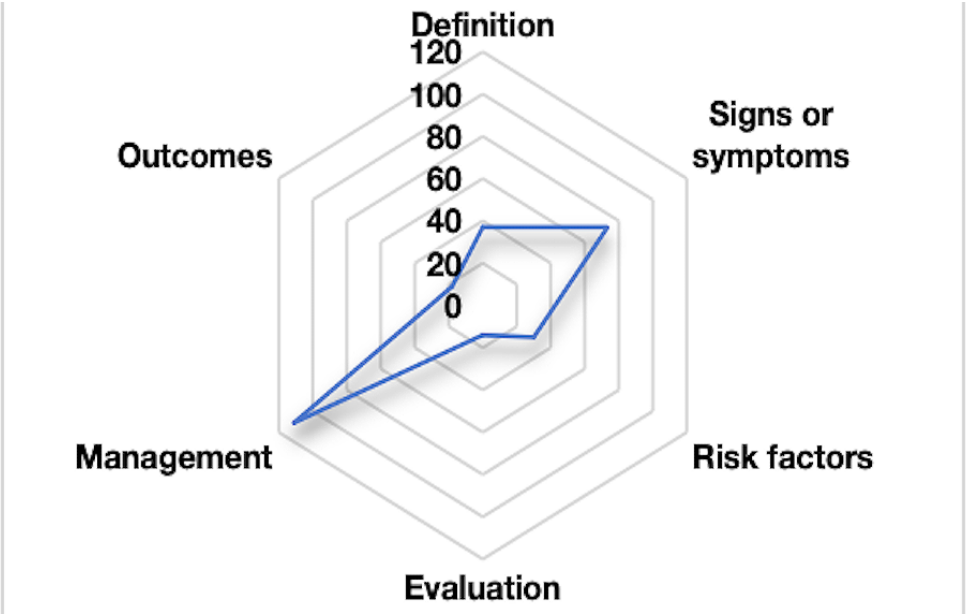
Analysis of Video Content

According to the hexagonal radar chart, the most frequently discussed topic in all videos was managing HTSs, which appeared in approximately 72.5% (111/153) of the videos. This was followed by the symptoms and definitions of HTSs mentioned in 47.7% (73/153) and 24.2% (37/153) of the videos. However, the outcomes and risk factors of HTSs should have been addressed, with only 11.8% (18/153) and 19.6% (30/153) of the videos discussing these aspects. The least mentioned topic was the evaluation of HTSs, with only 9.2% (14/153) of the videos adequately covering evaluation, while 90.8% (139/153) of the videos provided little to no information on this aspect (Figure 4). An in-depth analysis of the hexagonal radar chart structures presented by various city tiers revealed a common phenomenon—regardless of city tier, the video content predominantly focused on managing HTSs, while the evaluation of HTSs was notably less addressed (Figure 5). This finding aligned with our overall evaluation of the video content, further confirming the distribution bias of video resources toward specific topics.

XSL•FO
RenderX

Figure 4. Hexagonal radar charts of the content of videos on hypertrophic scars.



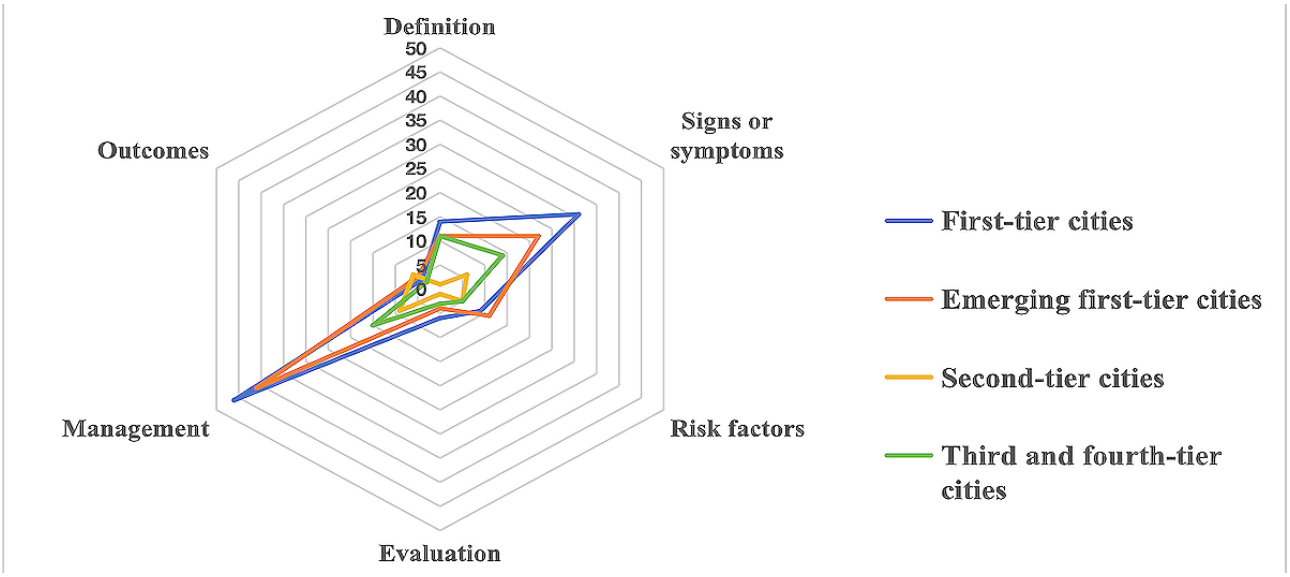


Figure 5. Hexagonal radar charts of the content of different city-tier videos on hypertrophic scars.

Assessment of Video Quality

We found that the median *JAMA* score for all uploaded TikTok videos was 1 (IQR 1-2). When we used the mDISCERN score to assess the usability and reliability of the videos, the median score was 2 (IQR 2-3). Specifically, the median GQS score for the overall quality of the TikTok videos was 2 (IQR 2-3), while the median HONcode score was 3 (IQR 3-4).

To explore whether health care professionals from different departments and cities influenced the quality and reliability of videos, we conducted a detailed categorization based on departmental affiliations and city tiers. The results showed slight differences in the quality scores, specifically *JAMA*, GQS, mDISCERN, and HONcode, among videos uploaded from 1 to 3(IQR 1.75-2.25), indicating an overall low quality of the videos. There was little variation in video quality ratings among different city levels; HONcode ratings were primarily concentrated at 3 (IQR 3-4) points, suggesting moderate overall content quality. Further analysis revealed that videos related to burn plastic surgery and burn surgery had relatively high-quality ratings, with HONcode score of 3.25 and an mDISCERN rating of 3. These departments exhibited stronger professionalism and scientific content. However, the videos suffered from insufficient interactivity, indicated by fewer likes and shares, resulting in a lower dissemination effect compared to dermatology videos.

For new first-tier cities, the video quality ratings (GQS: 2 and mDISCERN: 2) were comparable to those in first-tier cities. In addition, the median upload time for these videos was shorter (119.5 days compared to 188 days), indicating that the content was timelier. In contrast, videos from third- and fourth-tier cities achieved HONcode ratings of 3 and mDISCERN ratings of 2, showing no significant disadvantage in terms of quality. However, these cities had lower upload volumes and interaction metrics, averaging 51.5 likes and 10.5 comments. This could be attributed to limited medical resources and a smaller number of creators in those areas.

XSL•FO
RenderX

Correlation Analysis

The nonnormal distribution of the data led us to use Pearson correlation analysis to investigate the relationships between different video variables and all evaluation scores (Table 10). We found that each video variable positively correlated with the scores obtained from the 4 evaluation methods. Notably, likes, comments, favorites, and shares were the only variables that showed significant correlations with all evaluation scores (P<.001), indicating that higher-quality videos tended to be more appreciated by viewers. Specifically, the number of days since video upload was significantly positively correlated only with GQS scores (r=0.393; P<.001) and mDISCERN scores (r=0.273; P<.001). In contrast, video duration did not significantly correlate with the evaluation scores (Table 10).

[e]The correlation is significant at a significance level of .01 (2-tailed).

In addition, we used Spearman correlation analysis to reveal the relationships between different video variables. We observed a positive correlation between the following variables: likes and comments (ρ=0.777; P<.001), likes and saves (ρ=0.941; P<.001), likes and shares (ρ=0.904; P<.001), likes and uploads (ρ=0.534; P<.001), comments and saves (ρ=0.781; P<.001), comments and shares (ρ=0.820; P<.001), comments and uploads (ρ=0.404; P<.001), saves and shares (ρ=0.897; P<.001), saves and uploads (ρ=0.499; P<.001), and shares and uploads (ρ=0.564; P<.001). Meanwhile, there was no significant relationship between video duration and other variables (Table 11).

Discussion

Principal Findings

Health problems are crucial and need daily attention, accurate assessment, and timely intervention. With the increasing popularity of the mobile internet, it has become one of the most popular ways to obtain health and medical information. A survey shows that 70% of internet users rely on the internet as their primary source of health information [45]. In this cross-sectional study, we used *JAMA* GQS, mDISCERN, and HONcode tools to evaluate the quality and reliability of HTS-related videos on the Chinese version of TikTok (Douyin). The results showed that the quality and reliability of HTS-related videos from TikTok were generally moderate. From the perspective of video sources, HTS-related videos were mainly released by health professionals. TikTok has strict verification rules to protect users' interests, information security, and content reliability, and it requires only certified institutions or individuals to share medical-related videos on the platform [46]. In terms of video content, the video integrity was insufficient. Most (111/153, 72.5%) of the videos were related to HTS management. From the perspective of video classification, compared with other departments and cities, the videos uploaded by health professionals in burn departments and burn plastic-surgery departments, and videos produced in first-tier and emerging first-tier cities, were of slightly higher quality. Users should exercise caution when seeking information on HTSs from TikTok. It is advisable to choose videos uploaded by health care professionals from burn departments and burn plastic surgery departments, and in the Chinese context, those produced in first-tier and emerging first-tier cities.

Analysis of Overall Video Quality and Correlation

Our research uncovered an interesting phenomenon—only a few (1/153, 0.7%) videos thoroughly covered all aspects of HTSs, offering authoritative and practical guidance. Most (111/153, 72.5%) videos focused mainly on treatment methods, with symptom descriptions coming next and preventive measures mentioned less frequently. This may be related to the format of the TikTok platform, where video lengths vary; however, according to the latest statistics, the average length of popular videos is about 40 seconds [47]. This characteristic requires creators to present health information within a limited time frame, thereby affecting the depth and coverage of the video, and encourages users to create multiple videos on the same topic, each focusing on different aspects [48]. Our findings support this observation. Because a single video cannot cover all 6 core aspects of HTSs due to time constraints, users tend to split these into multiple videos presented as a series [46]. However, social media platforms usually recommend videos based on algorithms or randomness, making it difficult for users to access comprehensive health information systematically [49].

XSL•FO
RenderX

In the evaluation process of 153 videos, *JAMA*, GQS, mDISCERN, and HONcode scale values rated by experts showed high consistency (Cohen κ>0.80). Most videos on this platform did not receive high scores based on evaluations using *JAMA*, GQS, mDISCERN, and HONcode scales. This suggests that short videos about HTSs have poor quality and reliability. According to the recommendation algorithm of TikTok, people may primarily watch recently uploaded videos, and longer videos might cause viewers to lose patience and interest, leading to video skips. In addition, this mechanism determines that videos with more likes are more likely to be recommended; therefore, popular videos with lower quality have become more popular, further exacerbating the gap between video quality and popularity. We also found that videos from third- and fourth-tier cities received higher scores; however, this result only partially reflects the quality and reliability of their video content. The main reason is the relatively limited sample size from third- and fourth-tier cities, which may introduce some statistical bias. Therefore, caution is needed when interpreting these scores to avoid misinterpretation or misleading conclusions. To address this issue, we recommend that short video platforms introduce professional certification for experts and use unique markers to improve the trustworthiness of medical video content and reduce the spread of misinformation. The review standards for content uploaders on short video platforms are not yet comprehensive and strict. A significant number of nonprofessionals are still posting medical and scientific videos, which, to some extent, affects the accuracy and authority of the content [19]. Therefore, platforms should improve their verification and management procedures to ensure the professionalism and reliability of medical videos.

Our research discovered a potential link between video attributes and evaluation scores. We found a positive relationship between video length and evaluation scores, indicating that longer videos may improve quality by offering more informative content. However, this correlation was not statistically significant (P>.05). Previous studies have suggested that high-quality videos are often longer, which is consistent with our findings [50,51]. Excessively long videos might decrease viewer interest, resulting in fewer views, likes, and user engagement. This decrease in interest may stem from reduced viewer motivation despite the comprehensive content [52]. Therefore, publishers should consider video length carefully to maintain viewer interest and effectiveness of dissemination while upholding content quality. In addition, metrics, such as likes, comments, favorites, and shares, can gauge video popularity. Our analysis found significant positive correlations (P<.001) between these metrics and evaluation scores, indicating that high-quality videos are more likely to receive viewer approval. This finding aligns with the research conducted by Kong et al [12], which evaluated the quality of TikTok videos focused on diabetes health education. Their study found that higher-quality videos tend to receive greater recognition from audiences, evidenced by increased praise and sharing rates. In addition, our research revealed a positive correlation between the upload time of videos and their quality ratings, such as the GQS and mDISCERN scores (P<.001). This suggests that audiences prefer more timely and relevant content. Similar to the findings by Kong et al [12], we observed that the upload timing of videos is positively correlated with user engagement. However, in contrast to the work of Kong et al [12] and other studies that examined YouTube videos as sources of health information, our research found that TikTok videos received lower overall quality ratings. Specifically, in this study, the median *JAMA* score for TikTok videos was 1 (IQR 1-2), while YouTube videos typically received higher ratings in comparable studies (Kong et al [12] reported a median score of 2.5). This disparity may be attributed to the distinct characteristics of each platform. The short video format of TikTok, usually limited to 40 seconds, restricts the depth of content, whereas YouTube allows for longer videos that are more likely to adhere to *JAMA* and HONcode standards for comprehensive information. Furthermore, we found that interaction metrics for TikTok videos, such as likes and shares, were significantly correlated with GQS and mDISCERN ratings (r=0.740 and r=0.394, respectively; P<.001). This supports the conclusion made by Kong et al [12] that high-quality videos tend to engage audiences more actively. In addition, our study revealed variations in interaction metrics among medical professionals from different departments and cities, with videos uploaded from first-tier cities showing higher rates of likes and shares (P<.05). This finding has not been extensively explored in research on other platforms, suggesting that user behavior on TikTok may be influenced by unique regional and professional factors.

Analysis of Evaluation Tools

This study comprehensively used *JAMA*, GQS, mDISCERN, and HONcode to evaluate the quality and reliability of TikTok short videos, mainly based on the considerations mentioned subsequently. First, each benchmark focuses on different dimensions. *JAMA* evaluates authorship and transparency, GQS evaluates overall content quality, mDISCERN focuses on information reliability, and the HONcode examines the ethics and credibility of health information. Second, by integrating multiple benchmarks, it is possible to more comprehensively capture the differences in quality and reliability dimensions in short videos. Third, the multibenchmark method improves the objectivity of evaluation and avoids bias that may arise from a single benchmark. However, we also recognize that these benchmarks were not originally designed for short videos and may pose applicability challenges. For example, *JAMA* and HONcode standards are commonly used to evaluate formal or long-format medical content (websites, journals, or organizational publications). However, this study attempts to extend their application to user-generated content on the TikTok short video platform. These videos mainly focus on visual effects and have a duration between 33 and 58 seconds, so they may not fully meet the requirements of *JAMA* standards for content depth and information transparency. To overcome this challenge, 2 scoring experts had a detailed discussion on the benchmark before scoring and adjusted the scope of application of the scoring criteria. For example, the “disclosure” rating item focuses on whether the video identifies the publisher’s identity and affiliation rather than detailing funding sources or advertising disclosures. The rating experts also focus on evaluating whether the core medical information of the video is accurately conveyed based on the video duration limit rather than comprehensive coverage. By adjusting the scope of

XSL•FO
RenderX

application of these benchmarks (such as simplifying citation source standards), they still have reference value in evaluating the accuracy and credibility of core medical information in short videos. In addition, the review study by Li et al [53] indicates that mDISCERN is the most commonly used evaluation tool for health information videos. However, the review mainly focuses on long-format health education content and needs to explore the applicability of mDISCERN, specifically on short video platforms. Secondly, mDISCERN's single benchmark may need to be able to cover the multidimensional quality assessment needs in short videos. Therefore, our study attempts to compensate for the dimensions that a single benchmark may overlook, such as video transparency and overall content quality, by combining other benchmarks, such as *JAMA* and GQS. Therefore, this study chooses to comprehensively use multiple benchmarks to evaluate the quality and reliability of short videos from different perspectives. Future research should further optimize and develop evaluation tools for short videos to enhance their applicability and scientific validity.

Limitations and Future Directions

This research is the first to use 4 evaluation tools (*JAMA*, GQS, mDISCERN, and HONcode) to comprehensively evaluate the quality and reliability of high-frequency videos about HTSs on the TikTok platform. The study also includes an in-depth analysis of the relationship between video characteristics (likes, comments, favorites, and shares) and video quality. However, there are limitations to this study. First, the sample is limited to videos uploaded on the Chinese TikTok platform, which may limit the generalizability of the findings to other languages (such as English) and platforms (such as BiliBili). Despite focusing on Chinese TikTok, the research aligns with studies on videos from various platforms. Given the prevalence of HTS as a health issue, the findings may offer insights for video content in other languages and platforms (such as international versions of TikTok and YouTube). Second, there is a lack of standardized methods for evaluating health information video content on TikTok [46]. The study used 4 standardized evaluation tools due to their proven effectiveness in assessing video quality on media platforms and their previous use in studies evaluating TikTok video quality [54,55]. However, these assessments are somewhat subjective. Despite 2 raters confirming the scores and using Cohen κ to quantify interrater reliability, subjective differences cannot be ignored [20]. This highlights the need for the development of more suitable scoring standards. Third, limiting the analysis scope to verified accounts may result in certain limitations, such as not including videos published by ordinary users (such as patients) or unverified accounts. These videos may contain patients' firsthand experiences or other nonprofessional information, which can impact the comprehensiveness of research conclusions. Future research should consider expanding the scope of analysis and adopting broader validation criteria to cover a more diverse range of video sources. Fourth, although we only selected videos uploaded by medical professionals certified by the platform, we cannot completely rule out the ambiguity of the author's identity information. For example, some uploaders may not be the video's actual creators or information providers but may only participate in video publishing. This uncertainty may affect the accuracy of *JAMA*'s benchmark "authorship" score, potentially leading to bias in research results. Fifth, there are inherent issues with viewing TikTok as a platform for disseminating health information. TikTok's recommendation algorithm tends to push videos that easily attract attention rather than the most scientifically sound ones. This mechanism may lead to the dissemination of misleading or incomplete information. The subject of this study is limited to short videos related to HTSs on the TikTok platform, and all videos are uploaded by medical professionals. Although this choice ensures the scientific and credible nature of the video content, it also limits the generalizability of the research results. Videos related to HTSs uploaded by other groups, such as ordinary users or unverified health influencers, were not included in the analysis, which may limit the applicability of the research results to the broader dissemination of short videos related to health. In addition, the data source of this study is limited to Chinese TikTok (Douyin). The platform culture, user behavior, and regulatory policy may differ from the international version of TikTok or other social media platforms. Therefore, the research results may not directly apply to short video platforms in other countries or regions. In addition, TikTok's video duration limit (usually within 40 s) poses a challenge to the comprehensiveness of health information. Although short videos on the platform can attract viewers to understand a topic quickly, their structure and depth often need to be improved, which may not meet the audience's needs for complex health issues. Therefore, the effectiveness and limitations of TikTok as a tool for disseminating health information need to be further explored.

In addition, there are other evaluation criteria, such as the Video Popularity Index, that can be considered for assessing the quality of health-related information [56]. We recommend that future research incorporate various evaluation methods and platforms to assess the quality of video information more accurately.

The rapid advancement of internet technology and the rising health standards have led to the growing popularity of internet-based health promotion methods. Patients have shifted from being passive recipients to seeking health information actively [20]. With the widespread use of electronic devices, such as smartphones, and the flourishing multimedia technology, visual social media has become a crucial channel for accessing health information. However, the quality of video content varies greatly, leading to significant challenges. Some videos are misleading and provide inaccurate information to viewers, prompting professionals to advocate for stricter regulations. The Chinese government recently issued guidelines for media platforms to publish scientifically accurate health information, a move with global implications [57]. Enhancing the quality of health promotion videos has become a pressing issue requiring all stakeholders' attention. A high-quality health promotion video should be scientifically accurate, appeal to a broad audience, and be easily understandable while eliminating any misleading content. Therefore, rigorous evaluation of video quality is essential to ensure the dissemination of reliable information. Future research should focus on constructing and optimizing platforms to better cater to the public's health information needs.

XSL•FO
RenderX

Conclusions

This research gathered 153 videos about HTSs from TikTok, a popular short video–sharing social media platform in China, and comprehensively evaluated their information quality. The findings revealed that the videos lacked reliable sources and content quality. Overall, videos on the topic of HTSs produced by health care professionals from the burn department and burn plastic surgery department as well as those from first-tier and emerging first-tier Chinese cities demonstrated more significant insights regarding quality and reliability. They provide audiences with more reliable medical information. Therefore, people may prefer content from these departments and cities when seeking information about HTSs. As video-sharing platforms become increasingly popular sources of health information, it is essential to improve regulation and quality control. Users should be cautious when seeking health care management information on short video platforms. To ensure access to accurate information on hypertrophic scarring, we recommend referring to professional and authoritative sources and platforms to safeguard health effectively.

Abstract

Background: Patients with knee osteoarthritis have a considerable need for information about their condition, its progression, and available treatments. Decision-making is often complex and requires evidence-based health information material (HIM). When medical consultations do not sufficiently address patients' needs, many seek additional information independently.

Objective: This study aimed to examine the quality of German-language HIM on knee osteoarthritis treatment and its suitability for supporting informed choice. In particular, the study analyzed the content of the HIM and assessed the balance in the presentation of treatment options.

Methods: A descriptive cross-sectional study was conducted. HIM was identified through a combination of search strategies, including a systematic internet search using commonly used German terms related to the treatment of knee osteoarthritis. Identified HIMs were independently assessed by 2 raters using the validated Mapping the Quality of Health Information (MAPPinfo) checklist, which operationalizes the criteria of the Guideline Evidence-Based Health Information. Information quality was calculated on a scale from 0% to 100%, representing compliance with the quality standard. A descriptive content analysis was also carried out to examine the range and balance of treatment options presented, as well as the reporting of benefits and complications associated with total knee arthroplasty (TKA). The presence of certification was recorded.

Results: A total of 94 HIMs were included. On average, the material met 14.6% (SD 9.4%) of the quality criteria. HIM from public and nonprofit providers performed better (mean 40.1%, SD 3.6% and mean 37.2%, SD 23.1%, respectively) than those from other providers. Overall, 14 HIMs presented treatment options in a balanced manner. Among the 78 HIMs that covered TKA, 38.5% (n=30) did not report any benefits, and 35.9% (n=28) omitted potential complications. Certified HIMs showed only moderately higher information quality than uncertified material (mean 26.8%, SD 16% vs mean 12.7%, SD 5.9%).

Conclusions: Our results highlight the urgent need to improve the quality of German-language HIM on knee osteoarthritis. The deficits identified are fundamental and affect all dimensions of information quality. Although HIM from public or nonprofit organizations has better information quality, this does not facilitate informed choice. The frequent omission of complications and benefits of TKA and the unbalanced presentation of treatment options can influence decisions. Until structural improvements are made, patients seeking quality information should favor material from public or nonprofit providers. Additionally, the MAPPinfo checklist could form the basis of a differentiated certification system to make information quality more transparent for patients.

Introduction

Knee osteoarthritis is a globally prevalent, chronic degenerative joint disease that poses a significant burden on affected individuals, particularly in advanced stages. It is characterized by progressive cartilage degradation but affects the entire knee joint, leading to pain, stiffness, and restricted mobility. These factors significantly impair patients' quality of life and mobility [1]. In 2020, the self-reported 12-month prevalence of osteoarthritis among adults aged 18 years and over in Germany was 17.1%. The condition affected women more frequently than men, with prevalence rates of 21.6% and 12.4%, respectively. The prevalence increased substantially with age [2]. Another study estimated the all-time age- and gender-standardized relative prevalence of knee osteoarthritis at 10.6% (11.8% in women and 9.4% in men) [3].

Treatment options range from conservative interventions such as physiotherapy and pain management to surgical procedures, including joint-preserving and joint-replacing interventions [1,4]. Total knee arthroplasty (TKA) is an established treatment option associated with high expectations regarding pain relief and the restoration of mobility [5]. In 2019, Germany, along with Switzerland, Finland, and Austria, had the highest rates of TKA. While the Organisation for Economic Co-operation and Development average was 137 procedures per 100,000 inhabitants, these countries performed over 200 TKA [6]. A German study on second opinions found that only 40% of recommendations in favor of TKA procedures were confirmed by a second orthopedic surgeon in an arthroplasty center [7]. Studies on patient satisfaction following TKA show heterogeneous results, influenced by methodological limitations related to measurement tools and study quality [8,9]. Dissatisfaction can stem from unmet expectations, which in turn may result from insufficient or unbalanced provision of information [5].

The decision for or against a particular treatment option for knee osteoarthritis is complex [10]. Insufficient or inadequate information can be a major barrier to informed decision-making [11]. Various studies suggest that patients feel inadequately informed about their condition, its prognosis, and the available treatment options [11-13]. Moreover, TKA is frequently perceived as an inevitable treatment choice [10,12,14,15]. Research indicates that conservative treatment options are often not offered, used, or fully explored before surgical interventions take place [12,13,15,16]. At the same time, there is a clear patient demand for comprehensive information on conservative treatment options, including their benefits and risks [17,18]. The provision of health information material (HIM) regarding TKA can be challenging for various reasons. Decisions in favor of surgery are sometimes made before a formal indication has been established, leading to selective information dissemination [12]. Furthermore, information provided during the indication process for TKA tends to emphasize the benefits of surgery, and patients generally tend to overestimate the benefits of such a procedure while underestimating its risks [12,19].

Dissatisfaction with information provision can lead patients to seek information independently, particularly online [20]. Individuals with chronic illness are among the most frequent users of online health information [21]. Internet search behavior is influenced by factors such as age, gender, socioeconomic status, and education level [20,22]. Despite the importance of doctors and family members as primary sources of information, many individuals rely on the internet as a key research platform for health-related topics [23,24]. Depending on the study, between 68% and 74% of German respondents report using the internet to search for HIM [24,25]. The most commonly used sources include specialized health websites, websites of doctors, hospitals, and health care institutions, as well as commercial websites. Information on treatment options is most frequently sought on the websites of doctors and hospitals [24]. Trust in online HIM varies considerably and is often influenced less by content itself than by factors such as readability and design [21,23].

Informed choice is increasingly recognized as a quality standard in health care and is embedded in ethical principles [26]. An informed choice is defined as one based on the best available evidence regarding the benefits and risks of all treatment options and aligned with the patient's personal preferences [27]. With the introduction of the German Patients' Rights Act in 2013, which was incorporated into the German Civil Code (Section 630a-630h BGB), comprehensive patient information became a legal requirement. Furthermore, the inclusion of TKA in the second opinion process in 2021 reinforced the importance of an informed choice [28]. A key requirement for an informed choice is the availability of evidence-based HIM, which objectively, transparently, comprehensively, and understandably presents the advantages and disadvantages of medical or health care interventions. The 2017 Guideline Evidence-Based Health Information (Guideline EBHI) provided recommendations for the development of such material [29].

The quality of HIM with regard to knee osteoarthritis and TKA has already been assessed with several tools and in various countries. Findings indicate that quality varies widely and is often deemed inadequate [30-36]. None of the tools used in the previously conducted studies is considered fully adequate to comprehensively assess the quality of HIM based on the quality concept of the Guideline EBHI [37].

This study aimed to evaluate the quality of German-language HIM on the treatment of knee osteoarthritis. Specifically, it sought to determine whether German-speaking patients can make an informed choice based on the available HIMs. In particular, the study analyzed the content of HIM, assessed the balance in the presentation of treatment options, and identified key characteristics of the HIM.

Methods

Design

This study is part of a project to develop an evidence-based informed consent form for treatment decisions related to knee osteoarthritis [38]. Using a descriptive cross-sectional design, this study assesses compliance with evidence-based quality standards in HIM about knee osteoarthritis treatment. Initially, the plan was to evaluate the quality of printed information leaflets distributed by doctors and received by patients enrolled in an exploratory study [12]. However, due to the low response rate to the leaflet collection, the methodology was adapted to include online HIM. The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) statement was used for the reporting [39].

Sample and Search Strategy

From January to July 2021, we invited doctors and patients participating in an exploratory study on information and decision-making processes to provide printed material on the treatment of knee osteoarthritis [12]. Specifically, we asked 3 general practitioners, 4 office-based orthopedic specialists, and 1 hospital in an urban metropolitan area in western Germany to contribute. In addition, 13 patients, recruited both regionally and nationwide, were invited to contribute material. Participants were asked to send their material to us electronically; for those unable to do so, prepaid return envelopes were provided. However, only sporadic printed material was received from doctors, and none from patients. To supplement the collected data, we conducted an exploratory internet search in April 2022 using the Google search engine. This search targeted German-language information provided specifically by medical practices and clinics. Using the German term for knee osteoarthritis, the first 5 pages of search results were reviewed, with browser settings reset to default. This first step aimed to provide an overview of the type and scope of health information available.

In May 2023, a systematic search was conducted to expand the scope of the existing data. This search was also performed using Google, the most widely used search engine in Germany [40], with browser settings reset and incognito mode activated to minimize personalization of search results. We used Google Trends analysis [41] to identify the most popular German search terms relating to treatments for knee osteoarthritis. As TKA was a popular topic, a separate search term was used for this treatment option. For knee osteoarthritis, the term “Kniearthrose” was used, while for TKA, the term “Knie TEP” was applied. The initial 50 search results for each search term were extracted and documented in a Microsoft Excel spreadsheet. Additionally, known sources of health information not captured in the Google search results were manually added to ensure comprehensiveness.

Eligibility Criteria and Screening

HIM was included if it met the following criteria: (1) it provided information about the treatment of knee osteoarthritis, (2) addressed lay audiences, and (3) was written in the German language.

For the internet search, additional criteria were applied, such as websites were included regardless of how the content was presented. Google results marked as advertisements were excluded. Websites were also excluded if (1) they consisted exclusively of patient testimonials or (2) the information was not publicly accessible.

HIM identified across all 3 searches was consolidated, and duplicates were removed. When multiple websites from the same provider addressed different search terms, they were counted as a single HIM if the content was clearly interconnected and there was overall coherence. We defined the coherence of HIM on the basis of the structure. We consider a system of hierarchically organized pages from the same provider to be one HIM, whereas a referral to another provider, for example, is not considered to be part of the same HIM.

Selection criteria were independently reviewed by 2 researchers, and disagreements were resolved by a third reviewer. For the internet searches, copies of the included and excluded HIM were saved as PDF files so that the original could be accessed in the event of website changes during the course of the study.

Data Collection

All HIMs were categorized based on 3 basic variables: provider, country, and certification. Providers were classified into 8 categories, including commercial providers, hospitals, medical practices, nonprofit organizations, publicly funded providers, specialist associations, health insurance companies, and self-help groups. As German-language HIM can come from various countries, a further classification was made according to the provider’s country of origin, that being Germany, Austria, or Switzerland. Regarding certification, distinctions were made based on whether the HIM held any external certification or recommendation and, if so, from which organization.

Quality Assessment

The quality assessment was carried out using the Mapping the Quality of Health Information (MAPPinfo) checklist [42], which is based on the Guideline EBHI [29]. It is the first tool to implement the recommendations of the guideline in a precise way, allows the assessment to be based only on HIM without the need for the search of additional information, and can be reliably used by people without special training or expertise in evidence-based practice. Therefore, the quality assessment process is much more transparent and accessible to a wider audience. The MAPPinfo checklist consists of 19 items that evaluate the following 4 key aspects of quality: definitions, which refer to the target audience and the purpose of the information; transparency, which addresses how the information was prepared, including details on authorship, funding, timeliness, and sources; content, which focuses on the informational content such as the explanation of options and the presentation of benefits and harms; and presentation, which examines the suitability of how the content is delivered. The checklist includes 11 items assessed using a dichotomous format (fulfilled/not fulfilled) and 8 items assessed using a trichotomous format (fulfilled/partially fulfilled/not fulfilled). The total number of applicable items depends on the specific content of the HIM, with certain items, such as C7/P4, used only for

XSL•FO
RenderX

diagnostic decisions and others, such as P7, applied only when charts are used to visualize frequencies. The total score of the MAPPinfo checklist, which ranges from 0% to 100%, represents the information quality and reflects the extent to which the criteria of the Guideline EBHI are met.

The psychometric properties of the checklist had been validated in previous studies, confirming its suitability [42]. The assessment process and documentation were carried out using the Microsoft Excel–based MAPPinfo Evaluation Toolkit, which includes several worksheets. These enabled the collection of independent evaluator ratings, plausibility checks, identification of discrepancies, and documentation of consensus, as well as tables with calculations of reliability and information quality and the visualization of the results [43].

The MAPPinfo rating was carried out independently by 2 master students (LMR and JS), followed by a consensus process. In the case of disagreement, a third rater (SZ) was consulted, and consensus was reached through discussion. To ensure high interrater agreement, the 3 raters independently assessed a sample of 10 preselected HIMs and discussed discrepancies in their assessments, developing a common understanding of how the criteria should be applied to the specific health problem of knee osteoarthritis.

Content Mapping

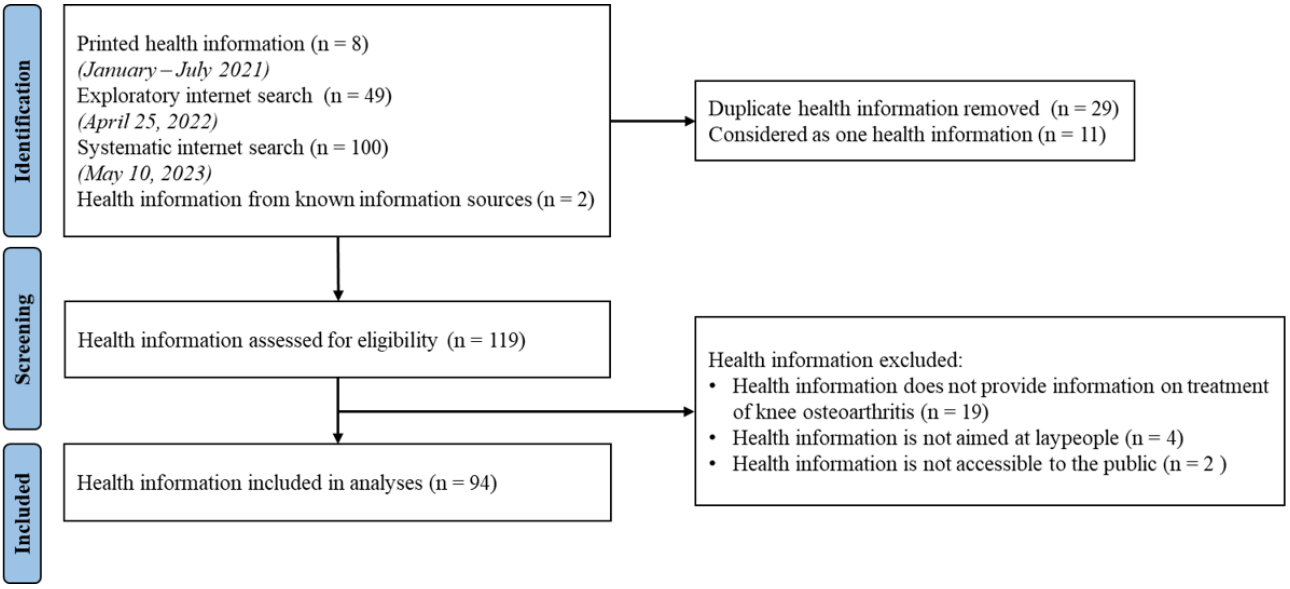
The MAPPinfo checklist already includes the aspects of trustworthiness and appropriate presentation of content. In addition, the content of the HIM was systematically extracted using predefined criteria, including information on the complications and benefits of TKA, treatment options for knee osteoarthritis, anesthesia options, and complications related to anesthetics. A subjective evaluation was also conducted to assess whether the treatment options were presented in a balanced manner. The criteria for complications of TKA were determined using the standardized list of the Knee Society [44], the criteria for benefits of TKA and the treatment options were defined using the developed evidence-based informed consent forms [38], and the definitions of the German consensus guideline on knee osteoarthritis [4]. The extraction process was organized in an Excel matrix, with both the criteria and the matrix itself piloted and refined based on an initial review of the 10 preselected HIMs. Where classification was not feasible, free-text entries were permitted to capture relevant details. The assessment was initially conducted by one rater and subsequently reviewed by a second rater to ensure consistency and accuracy.

Data Analyses

Data were analyzed using the Excel-based MAPPinfo Evaluation Toolkit [43]. We calculated a score ranging from 0% to 100% for each HIM. Each item was assigned 1 point if it was fulfilled, 0.5 points if it was partially fulfilled, or 0 points if it was not fulfilled. Items C4/P1 to C7/P4, which reflect both content and presentation, were given double weighting. The total score was calculated by dividing the sum of all item points by the maximum possible points for all applicable items and expressing the result as a percentage. A score of 100% indicates full compliance with the quality criteria of the Guideline EBHI. Additionally, we determined the overall mean score for all HIMs, as well as the mean scores for each item, including the SD. The overall mean values were further analyzed descriptively for different values of the basic variables of the HIM. The content analysis was performed descriptively, using frequencies and proportions. Furthermore, a descriptive analysis was conducted to evaluate the presentation of treatment options by provider groups. The interrater reliabilities of the MAPPinfo ratings between the 2 raters were calculated at the item level using the T-coefficient. This method does not estimate the probabilities of expected agreement empirically from the given dataset but uses theoretical assumptions derived from the number of potential values that an item can receive [45]. Interrater reliabilities were considered moderate between 0.40 and 0.60, strong when higher than 0.60, and excellent when higher than 0.80 [46].

Ethical Considerations

As this study does not involve participants or participant data, ethical approval and informed consent were not applicable.



Results

Overview

Out of 159 identified HIMs, a total of 94 were included in the analysis (Figure 1). Within the total sample, commercial providers accounted for 37.2% (n=35), hospitals for 27.7% (n=26), medical practices for 25.5% (n=24), nonprofit organizations and publicly funded providers for 3.2% (n=3), professional associations for 2.1% (n=2), and health insurance companies for 1.1% (n=1). No HIMs from self-help groups were included. Certifications from 3 organizations were identified (Health Information System Action Forum [Aktionsforum Gesundheitsinformationssystem] (Afgis) [47], German Health Literacy Network [Deutsches Netzwerk Gesundheitskompetenz] (DNGK) [48], and Public Health Foundation [49]), most of which contain transparency criteria. In total, 13 of the analyzed HIMs were certified by at least one of these organizations, while 81 had no certification.

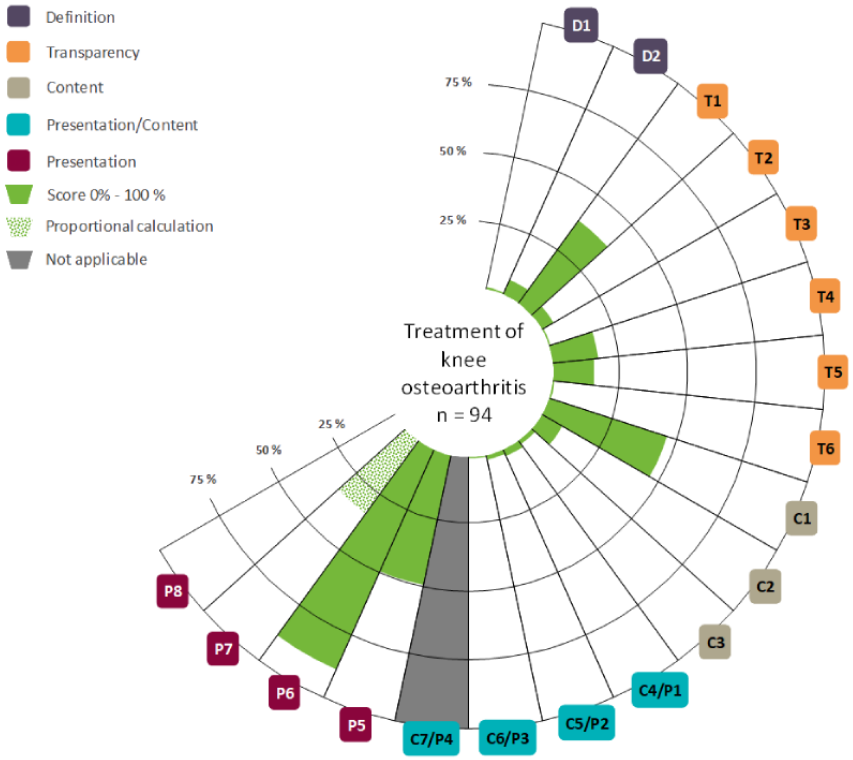
RenderX

Figure 1. Flowchart of the search and selection of health information material.



MAPPinfo Quality Assessment

The agreement between the raters was excellent (T=0.91, T minimum=0.6, T maximum=1). The 94 HIMs demonstrated a mean compliance of 14.6% (SD 9.4%) with the criteria outlined in the Guideline EBHI. Compliance with the quality standards ranged from 0% to 69% among individual HIMs. None of the HIMs met all criteria.

At the item level (Figure 2 [43]), the 3 criteria with the highest compliance were the avoidance of using narratives (P6; mean 88.3%, SD 32.1%), the use of neutral language (P5; mean 48.9%, SD 50%), and the explanation of the health problem (C1; mean 45.7%, SD 49.8%). Compliance with the quality standards (Table 1) was very low in some of the criteria. These include, for example, the use of gain and loss framing (P8; 0%), the reporting of a systematic search strategy (T6; mean 1.1%, SD 10.3%), the reporting of a strategy for managing conflicts of interest (T3; mean 1.1%, SD 10.3%), and the presentation of benefits (C5/P2; mean 2.1%, SD 14.4%) and harms (C6/P3; mean 1.1%, SD 10.3%).

Figure 2. Visualization of information quality created with the Mapping the Quality of Health Information Evaluation Toolkit. P7 only applies to 6 out of 94 health information materials and was therefore calculated proportionally.

Different levels of information quality were observed between provider groups, as well as between HIMs with or without certification, and between HIMs with different reporting of treatment options. HIM provided by publicly funded providers

XSL•FO
RenderX

(n=3) and nonprofit organizations (n=3) achieved higher information quality with an average of 40.1% (SD 3.6%) and 37.2% (SD 23.1%), respectively, compared to HIM from other providers (Table 2). HIMs with at least 1 certification (n=13) demonstrated higher information quality than uncertified HIMs (n=81), with an average of 26.8% (SD 16%) compared to 12.7% (SD 5.9%). However, information quality also varied within certified HIMs. Those provided by organizations recognized as reliable health portals by the DNGK [48] had higher information quality than other certifications. HIM providing balanced information on conservative and surgical treatment options (n=14) achieved higher information quality than those focusing on surgical (n=52) or conservative options (n=28). Information quality was comparable across countries of origin (Table 2).

Table 1. Information quality according to criteria.

Category	Criterion	Compliance (%), mean (SD)
D[a]1	The target group addressed by the HIM[b] is clearly defined.	1.1 (10.3)
D2	The HIM explains explicitly that an informed choice about a concrete problem should be facilitated.	6.4 (20.9)
T[c]1	The authors of the HIM are named.	37.8 (44.2)
T2	The funding source of the HIM is disclosed.	5.3 (22.4)
T3	A strategy for managing conflicts of interest is disclosed.	1.1 (10.3)
T4	The HIM indicates how up-to-date it is.	17 (26.8)
T5	The sources of information are named.	15.4 (28.3)
T6	The systematic search strategies underlying the generation of information are transparent.	1.1 (10.3)
C[d]1	The health problem is explained.	45.7 (49.8)
C2	The options are named and explained.	9 (20.6)
C3	The HIM makes statements about stochastic uncertainty.	2.1 (14.4)
C4/P[e]1	The natural course (in the case of diagnostic problems: the prevalence) of the disease is adequately presented.	3.2 (17.6)
C5/P2	The benefits are presented adequately.	2.1 (14.4)
C6/P3	The harms are presented adequately.	1.1 (10.3)
C7/P4	For diagnostic problems, information on the quality of the test is presented adequately.	N/A[f]
P5	The HIM uses neutral language throughout.	48.9 (50)
P6	The HIM does not use narratives that present relevant factual information.	88.3 (32.1)
P7	Graphics are designed in a suitable manner.	33.3 (37.3)[g]
P8	Information about benefits and harms is supplemented with complementary information (gain and loss framing).	0 (0)

Content Analyses

TKA was mentioned as a treatment option by 78 of the 94 HIMs. Within this subgroup, a third of the HIM did not report any complications (n=28, 35.9%) or benefits (n=30, 38.5%). The most commonly reported complications were joint infection (n=39, 50%), prosthesis loosening (n=30, 38.5%), and revision (n=25, 32.1%). In terms of benefits, pain relief was the most commonly reported benefit (n=32, 41%), followed by nonspecific statements about mobility (n=24, 30.8%) and general nonspecific statements about benefits (n=20, 25.6%; Table 3).

Within the same subgroup, 21 (26.9%) HIMs addressed the topic of anesthetics. When anesthetics were mentioned, the available options (different types of anesthetics) were mostly described. A total of 2 (9.5%) HIMs reported associated complications (Table 3).

The HIMs mentioned a range of treatment options for knee osteoarthritis. Pharmacological therapy was most frequently reported (n=75, 79.8%), followed by physiotherapy (n=70, 74.5%) and orthopedic assistive devices (n=53, 56.4%; Table 4).

Treatment options were reported in a balanced way in 14 HIMs, while 52 HIMs focused on surgical options and 28 on conservative options. The focus varied depending on the type of provider (Table 5).

[a]HIM: health information material.

Discussion

Principal Results and Implications

This study was designed to investigate the extent to which German-language HIM for the treatment of knee osteoarthritis can facilitate informed choice and to provide an in-depth analysis of contents published in this segment of health information. To this purpose, 94 HIMs from different providers were assessed using the validated MAPPinfo checklist, which operationalizes ethical and evidence-based minimum criteria for HIM aiming to facilitate informed choices. The content of the HIMs was then extracted and analyzed in a standardized manner.

The results indicate a concerning lack of information quality in the HIM analyzed, with an average of only 14.6% (SD 9.4%) of the minimum criteria necessary for informed choices being met. It is noteworthy that none of the HIMs met all the criteria in full (maximum score: 69%).

Deficits in the definition and content criteria are particularly critical. The definition of the target group and the formulation of the objective were fulfilled on average by only 1.1% (SD 10.3%) and 6.4% (SD 20.9%), respectively. Missing or insufficient information in these areas can cause uncertainty among users and contradict the requirements for an informed choice. The description of all possible options and the presentation of the choice between them was fulfilled on average by only 9% (SD 20.6%). Reporting on the natural course of osteoarthritis of the knee was fulfilled on average by only 3.2% (SD 17.6%). Similarly, the appropriate presentation of benefits and harms was fulfilled on average by only 2.1% (SD 14.4%) and 1.1% (SD 10.3%), respectively. It is crucial for patients with knee osteoarthritis to have a comprehensive picture of possible treatments and their consequences so that they can make a decision in line with their preferences and values. These areas were also identified by patients in previous studies as key information needs [11-13,17,18].

We found some differences in information quality between different providers. Health information from publicly funded and nonprofit providers had a higher average information quality of 40.1% (SD 3.6%) and 37.2% (SD 23.1%), respectively. The HIM with the highest quality (69%) also came from a nonprofit organization. On the one hand, this indicates that there is potential, but at the same time, it becomes clear that even these providers do not fulfil all the criteria. Overall, we therefore conclude that the HIM analyzed for the treatment of knee osteoarthritis does not support an informed choice.

According to the providers of the certifications, the certification of HIM is intended to reflect a quality standard. Our analysis showed that HIMs with at least 1 certification have a slightly higher information quality (mean 26.8%, SD 16%) than those without certification (mean 12.7%, SD 5.9%). Due to the predominant focus of these certificates on transparency criteria and the overall low information quality, the quality standard of the certifications appears insufficient. The DNGK certificate stands out here with an average information quality of 40.9% (SD 17.3%), which is mainly due to recommendations from publicly funded and nonprofit providers. However, the content requirements remain considerably below the requirements for an informed choice.

The latest update to the guideline on indication for knee arthroplasty reiterates that nonsurgical treatment should be attempted for at least 3 months before surgery is considered [50]. However, previous studies showed that conservative treatment options are often not sufficiently offered or used [12,13,15,16]. The analysis revealed that 85.1% (80/94) of HIMs mentioned at least 1 conservative treatment option, which at first glance appears to be helpful. However, due to the unbalanced presentation of this information, we have considerable doubts as to whether this really helps to meet information needs. Doctors are highly trusted and are often used as a source of information. [12,23,24]. However, only 3 HIMs from hospitals (n=26) and 1 HIM from medical practices (n=24) presented the treatment options in a balanced way. The majority of these presentations focused on surgical therapies, which could reinforce the impression that conservative options are less relevant and thus strengthen the impression of TKA as the only meaningful option [10,12,14,15]. Decision-making in the treatment of knee osteoarthritis is often complex due to the chronic and fluctuating nature of the condition. Patients are faced with the challenge of addressing their impairments or adapting their lives accordingly while weighing up the benefits and risks of the available treatment options. Their need for information may vary depending on the stage of the disease and

XSL•FO
RenderX

their personal circumstances. [10] This emphasizes the importance of comprehensive, balanced, and timely information to ensure that no treatment option is overlooked.

In the 78 HIMs that mentioned TKA as a treatment option, one-third did not mention complications or benefits at all. Serious complications, including but not limited to infections, implant loosening, revision surgery, and thromboembolic events, were mentioned in only up to half of the HIMs.

It is well-documented that patients frequently seek additional sources of information when they are provided with insufficient details by their health care professionals [20]. However, these findings suggest that, due to the generally poor quality of available HIM, this additional search is likely to be unsuccessful and may even place an additional burden on health care systems as doctors have to address the possibly incorrect information given to patients.

Previous studies evaluating the quality of health information on knee osteoarthritis and TKA did not use assessment tools that fully meet the criteria of the Guideline EBHI [29], which defines the standards needed to support informed decision-making, nor have they been extensively validated. Consequently, a direct comparison with our results is not possible. Nevertheless, these previous studies have also identified substantial weaknesses in the HIM they examined [30-36].

The literature repeatedly highlights the issue of inadequate health literacy and the associated difficulties in accessing, interpreting, and using health information effectively to make informed decisions [51]. While we acknowledge and strongly support the need to improve health literacy, it remains essential to ensure that appropriate HIM is available to support informed decisions when adequate health literacy exists. The findings of this study are in concordance with those of previous analyses of HIM, which indicate that such HIMs are currently not available [52,53].

The findings of this study underline the urgent need for health information providers to improve the quality of available HIM. The criteria required to support informed choices should guide these improvements. To address these challenges, initiatives are needed to strategically allocate public resources to the production of high-quality HIM and to encourage greater collaboration between developers of HIM.

The current range of certifications, which are designed to guarantee the quality of HIM, do not meet this objective adequately with regard to the HIM analyzed for the treatment of knee osteoarthritis. Furthermore, these certifications do not equip users adequately with the ability to recognize the individual strengths and weaknesses of HIM. One potential solution might be to establish a certification system based on the MAPPinfo checklist, explicitly assessing criteria necessary for informed choices. Moreover, the incorporation of visual representations of information quality could facilitate transparency for users by clearly indicating which criteria are fulfilled and where deficiencies exist. While numerous tools already exist to help users easily assess the quality of health information, a graphical representation of MAPPinfo information quality could offer a straightforward approach. The findings of our study suggest that patients with knee osteoarthritis seeking treatment-related information should prioritize HIM from publicly funded or nonprofit providers.

Strengths and Limitations

The strengths of this study include a systematic search strategy, use of the validated MAPPinfo checklist, excellent interrater reliability, and rigorous, systematic documentation of all assessment steps. However, it is important to acknowledge the limitations of the study. First, the search was conducted exclusively using Google, which may introduce a selection bias in an unknown direction. Furthermore, even though the sample was extensive, not all available HIMs could be identified. Second, it could be argued that evaluating HIM against criteria for informed choice may not reflect the intentions of all information providers, as some may claim that they do not explicitly aim to support decision-making. This approach was justified on the basis that users typically cannot discern the intended purpose of a given health resource or determine what information is necessary to support an informed choice. Consequently, it is reasonable to assume that users generally perceive HIM as suitable for decision-making unless it is explicitly and clearly stated otherwise by the provider. A further limitation concerns the temporary nature of the criteria used. At the time of this study, the criteria used in the MAPPinfo checklist represented ethical and evidence-based minimum standards. However, it is conceivable that additional criteria could influence informed choice to varying degrees, although such criteria have not yet been sufficiently validated and therefore could not be assessed.

Conclusions

Overall, our findings highlight the urgent need to substantially improve the quality of German-language HIM on the treatment of knee osteoarthritis to support patients in making informed choices. The identified deficiencies are fundamental and affect all dimensions of information quality. Furthermore, a substantial proportion of the HIM reviewed does not address critical issues, such as complications and benefits associated with TKA, and only a few present treatment options in a balanced way. Such deficiencies may potentially result in a biased perception of available therapies, which could influence patient decision-making.

Moreover, of the HIM analyzed for the treatment of knee osteoarthritis, only 1 out of 3 available certifications exhibited substantially higher information quality. However, it did not meet the comprehensive requirements needed to support informed choice. The MAPPinfo checklist has the potential to serve as a valuable instrument for more differentiated certification, highlighting both the strengths and weaknesses of HIMs. Furthermore, the establishment of initiatives aimed at enhancing cooperation among providers and strategically aligning public resources should facilitate the development of HIM that meets all the criteria of the Guideline EBHI. Until such initiatives are implemented, patients seeking the highest quality information are advised to consult health information provided by publicly funded or nonprofit organizations.

Abstract

Background: The internet and social media have been considered useful platforms for obtaining health information. However, critical and erroneous content about vaccines on social media has been associated with vaccination delays and refusal.

Objective: This study aimed to examine how social networks influence access to and perceptions of vaccine-related information. We sought to (1) quantify the proportion of individuals engaging with vaccine-related content on social media and to characterize their demographic and behavioral profiles through an internet-based population survey conducted in Spain and (2) to analyze vaccine-related sentiments and opinions in Spanish and Catalan posts on X (X Corp [formerly Twitter, Inc] and geolocate them using artificial intelligence.

Methods: Two complementary methodologies were applied. First, an observational study was conducted via a self-administered internet-based questionnaire among adults in Spain in 2021. Second, we analyzed Spanish- and Catalan-language posts from X, collected between March and December 2021. Sentiment analysis was performed using a workflow developed in Orange Data Mining (Bioinformatics Laboratory, Faculty of Computer and Information Science, University of Ljubljana). Geolocation was based on user-defined locations and visualized using Microsoft Power Business Intelligence. Social network analysis was conducted with NodeXL Pro (Social Media Research Foundation) to identify and characterize the 5 largest user communities discussing vaccines. Although based on independent data sources, the 2 approaches provided complementary methodological insights.

Results: Among the 1312 respondents in the survey, 85.7% (1124/1312) stated that they were regular social network users, and 66% (850/1287) reported having encountered antivaccine information on social networks. Of these, 24.3% (205/845) experienced doubts about receiving recommended vaccines, and out of those with doubts, 13.3% (27/203) refused at least 1 vaccine proposed by a health care professional. A total of 479,734 Spanish and Catalan posts on X were analyzed, with 54.44% (n=261,183) posts classified as negative, 28.18% (n=135,194) as neutral, and 17.37% (n=83,357) as positive. Sentiment varied across regions, with more negative posts appearing to derive from South America, with a mix in Europe and more positive posts in North America. Analysis of the topic words and key themes allowed the grouping of the predominant themes of the 5 study groups, which were (1) vaccination efforts during the COVID-19 pandemic, (2) issues of vaccine theft and struggles in managing and securing the

XSL•FO
RenderX

vaccine supply, (3) campaigns in the State of Mexico, (4) vaccination efforts for older adults, and (5) the vaccination campaign in Colombia to combat COVID-19.

Conclusions: High proportions of exposure to antivaccine content were reported by the surveyed population. Sentiment analysis and geolocation of posts on the social network X suggested a notable presence of Spanish-language posts categorized as negative, predominantly from South America. The thematic analysis of conversations on X may provide valuable insights into the population's opinions about vaccines.

Introduction

The critical and erroneous content about vaccines on social networks has posed a significant obstacle to immunizing the population against vaccine-preventable diseases [1-7]. A decline in vaccination coverage represents a threat to the herd immunity acquired in recent years through the efforts of health care professionals and could lead to outbreaks of diseases, such as the measles outbreak in Europe in 2023 - 2024 [8].

The crisis in the vaccination system and the resurgence of antivaccine movements are due to the increased accessibility of misinformation and the reduced credibility of health care personnel [9-11]. The internet and social media have changed the way the public accesses health information [12,13]. This information on social networks frequently contains incorrect data about vaccine effectiveness or data from antivaccine movements, which can influence the decision to reject vaccination before individuals even set foot in primary care centers [13,14]. A study published in 2020 stated that Facebook (Meta) pages that distrust established health guidelines are more effective at influencing hesitant individuals than government agencies [15]. Distrust in scientific positions could spread and dominate social network conversations over the next decade [15]. Exposure to antivaccine content on social media has been associated with delays and rejection of vaccination and is considered one of the major causes of vaccine hesitancy [3,16-19].

Current literature has yet to explain how the antivaccine movement continues to engage and persuade the public to reject immunization despite the efforts of vaccine advocates [16]. Antivaccine proponents on social networks have shown more active engagement patterns than provaccine groups. In a study published in 2020, analyzing Facebook users, it was shown that antivaccine groups on social networks, though a minority, had the potential to be more influential than provaccine groups. Moreover, undecided groups were not passive; they were the most active agents in the discussion. This fact favored the interaction of the undecided with antivaccine groups [15], and for this reason, intervention strategies were proposed to identify central and influential antivaccine groups to reduce their growth and the formation of future antivaccine or undecided groups [15].

X (formerly known as Twitter) has been an important source of information for studying vaccine hesitancy, as social media platforms have been considered effective tools for communication between individuals and organizations, but they have also been used as tools to spread false information and conspiracy theories about vaccines [20-22].

Several studies have been published analyzing public opinions or sentiments about vaccines on X using artificial intelligence (AI). These publications suggested that the analysis of social networks using AI should be considered by institutions and governments alongside surveys and other conventional methods to assess public attitudes toward vaccines [16,21,23-25]. AI techniques, such as natural language processing and machine learning, enable real-time sentiment analysis of social media posts, identifying shifts in public opinion linked to events or misinformation [21,24,26]. Social bots on platforms like Twitter can shape vaccine perceptions by amplifying both positive and negative sentiments [27,28]. AI tools track sentiment trends over time and across regions, offering insights into geographical variations in public opinion [21,24,25]. These insights can support real-time assessments of public confidence in vaccines, address the concerns of skeptics, and inform more effective communication strategies to enhance vaccine acceptance [24,29].

A prior study combining survey data with social media analysis, conducted in the context of influenza vaccination in the United States, illustrates a precedent for using these 2 methodologies in parallel. This study analyzed geolocated tweets using topic modeling techniques alongside individual-level survey data on vaccination attitudes and behaviors, offering insights into potential associations between social media content and offline public health outcomes [30]. In this line, our study applies a dual-methods design, seeking to capture complementary perspectives on public discourse and sentiment.

Our study aimed to determine how social networks influence access to and perception of vaccine-related information. To this end, we established the following objectives: (1) to quantify the proportion of individuals engaging with vaccine-related content on social media and to characterize their demographic and behavioral profiles through an internet-based population survey conducted in Spain and (2) to analyze vaccine-related sentiments and opinions in Spanish and Catalan posts on X, and geolocate them using AI.

XSL•FO
RenderX

Methods

Overview

This dual-methods design was developed to obtain a comprehensive exploration of vaccine-related communication by analyzing 2 independent but complementary data sources. The quantitative component consisted of a survey administered to adults residing in Spain, capturing self-reported attitudes and behaviors regarding vaccines. In parallel, the second component involved the collection and analysis of Spanish- and Catalan-language posts published globally on X. Both data strands were analyzed separately, involving distinct populations, and no direct linkage between participants was established. While the survey yielded structured quantitative data on personal vaccine-related behaviors and attitudes, the social media analysis provided insight into naturally occurring, public vaccine narratives and expressions within social media communities. The parallel, though independent, implementation of these methods allowed for an exploratory examination of how vaccine-related narratives are both consumed via self-report and expressed through spontaneous discourse, thereby offering different but complementary perspectives on the phenomenon without implying a formal methodological integration.

Survey Data Collection and Analysis

Study Design

We conducted an observational, cross-sectional study on individuals who had access to an internet-based survey from March to December 2021 (Multimedia Appendix 1). The inclusion criteria required participants to be aged 18 years or older and have the authority to make vaccination decisions for themselves or others in Spain. We obtained the information through an electronic, self-administered questionnaire designed by the project research team. A pilot test was performed before the definitive questionnaire was obtained. To ensure the rigor and validity of the study, an experienced research team with expertise in conducting surveys will be needed, thereby guaranteeing the quality and reliability of the instrument. Both were registered on a REDCap (Research Electronic Data Capture) web platform on a centralized server where the data remain in the custody of the Institut Català de la Salut (Catalan Health Institute). Through the REDCap web platform, we also built a database of the participants. Anonymous information was exported to the statistical packages used for subsequent analysis. The REDCap platform generated a link [31] for participation in the survey that was disseminated through scientific societies, social media, research institutes, pediatricians, and nurses in primary care.

Variables

The main variables of the questionnaire are listed in Textbox 1.

XSL•FO
RenderX

Textbox 1. Variables of the questionnaire.

Sociodemographic factors

- Sex
- Age
- Having children younger than 15 years
- Level of education

Information on the use of social network

- Use of social network and duration of use.
- Whether information about vaccines was sought on social networks.
- Which social network was used to search for vaccine information?
- The year of the first search for vaccines on social networks.
- Whether the search was related to COVID-19.

Antivaccine information on social network

- Whether they had encountered the antivaccine information.
- Whether such information had caused doubts.
- The type of doubts.
- Whether the information on social networks had led them to reject vaccines.
- Whether vaccines were rejected for a child and, if so, the child's age.
- Who initiated the doubt, and the gender, age, and education level of the person rejecting vaccination.

Opinions about vaccines on social network

- Whether they had received opinions against vaccines.
- Whether they had received opinions in favor of vaccines.
- Whether they followed a social network that generated doubts about vaccines or profiles against or in favor of vaccination.
- Whether they had made any comments against or in favor of vaccines on social networks.

Statistical Analysis

The data were gathered in an anonymized database using the REDCap platform. We conducted a descriptive analysis of the findings, categorizing qualitative or ordinal data using absolute and relative frequencies. The analysis was complemented within selected subgroups of interest to identify the factors independently associated with these results. Statistical analyses were performed with R software version 4.1.2 (R Foundation for Statistical Computing). In the statistical analysis, only complete cases were considered, and missing values were assumed to be missing at random.

X Insights and Social Network Analysis

Data Retrieval

Posts were gathered from X. The search string in order to retrieve posts was as follows: "vacunacion OR vacunacio OR vacunas OR vacunes OR antivacunas OR antivacunes OR antivacinacion OR antivacunacio." We relied on Spanish and Catalan keywords to retrieve our dataset, and geolocation retrieval was not used. Our data retrieval would also include hashtag versions of these keywords as well as any replies to posts that would have used these keywords. A total of 479,734 posts were captured (excluding reposts), and these were sent by 29,706 users. The step of excluding reposts greatly enhanced the clarity of the dataset. Due to the difficulties in assessing spam or "bots," no further processing was applied. The data were randomly sampled between March 2021 and December 2021 (see Table 1). This time period is selected because it aligns with the second phase of the COVID-19 vaccine, when vaccines were becoming more accessible to the general public. This 10-month window offers an overview during this important period.

XSL•FO
RenderX

Table . Overview of data (tweet volumes and total number of X users).

Month (2021)	Total number of posts	Total number of X users
March	54,837	40,093
April	53,793	39,426
May	53,613	39,114
June	54,499	38,590
July	54,074	40,170
August	54,002	39,303
September	47,141	33,402
October	35,071	25,545
November	35,417	27,944
December	37,287	29,706
Total	479,734	—[a]

[a]Not applicable

Sentiment Analysis

Orange Data Mining was used to create a workflow for sentiment analysis of the 479,734 posts that were captured. Sentiment analysis aims to calculate the sentiment for each post within the dataset. The study drew upon the multilingual sentiment lexicon built into Orange Data Mining. This sentiment analysis is based on unsupervised learning. Orange Data Mining draws upon a multilingual lexicon derived from affective norms for words across several languages, including Spanish. Lexicons are essentially lists of positive and negative words that can be used to determine the overall sentiment of a text. These are embedded in Orange Data Mining, and they can be downloaded elsewhere [32]

Moreover, in Orange Data Mining, depending on the content of each post, a score is provided to each post, such as −10 (ie, negative), 6 (which would be positive), and 0 (neutral). These scores are based on the positive and negative lexicons within the posts. An average sentiment score was also calculated by computing the average sentiment score of all 479,734 posts.

Although this sentiment analysis relies on a general-purpose lexicon, we acknowledge that in the context of vaccine-related communication, negative sentiment may encompass a broad spectrum of emotional expressions. These include not only rejection or hostility but also more nuanced affective states, such as concern, fear, uncertainty, grief, or anger. This is particularly relevant in vaccine discourse, where emotional responses may reflect hesitancy, confusion, or distress rather than outright opposition.

Location-Based Analysis

Location-based analysis was conducted by drawing upon self-defined user locations from X, entered into Microsoft Power Business Intelligence for analysis. A challenge with self-defined locations (ie, user-reported) is that as they allow users to enter free text, they may provide a city or region rather than the country. These are, therefore, better analyzed visually. Data were collected from April to December 2021. Location analysis focused on examining a specific time period in our dataset, that is, April 2021.

Social Network Analysis and Topic Insight

Social network analysis was conducted to identify the nature of the top 5 groups conversing about vaccinations in Spanish, drawing upon NodeXL Pro. Social network and topic analysis focused on examining April 2021, which provided a snapshot of key influencers at the start of our time. April was specifically selected because this was when the pace of vaccinations began to increase and mass vaccination centers began to upscale their operations.

Our study used NodeXL Pro to conduct social network analysis, examining how different users interacted with each other to identify patterns in interactivity. This included how users replied, retweeted, and mentioned each other. When these interaction patterns are analyzed in aggregate, they uncover hidden insights. These patterns were then used to assign each of the users to distinct “groups.” By analyzing the position of users within the network using betweenness centrality, it allowed the ability to identify influential users within the network. Our approach followed that of previous research [33]. In terms of specific methodological steps, the networks were laid out using the “Group in the Box” format. The graphs were directed. The graph’s vertices were grouped by cluster using the Clauset-Newman-Moore cluster algorithm [34]. The graph was laid out using the Harel-Koren Fast Multiscale layout algorithm [35]. By examining the most popular words, key posts, and tweets within the dataset, we assigned various themes to each of the groups. Using the above insights, we were able to identify the top 5 users within the network, drawing upon betweenness centrality to the key influencers within the network. An additional insight gained is the type of words being used by users within the network. Our analysis provides insight into the 2 words most often used together. This helps shed light on the issues users may have been talking about.

Ethical Considerations

This study was approved by the ethics and clinical Research Committee of the Institut Universitari per a la recerca a l'Atenció Primària de Salut (University Institute for Research in Primary Health Care; IDIAP) Jordi Gol i Gurina, with code 20/221-P. The study was conducted in accordance with the principles of the Declaration of Helsinki. The variables collected were treated anonymously to guarantee the confidentiality of the data, as established in Regulation (European Union) 2016/679 of the European Parliament and the Council of April 27 on Data Protection (General Data Protection Regulation) and the organic law 3/2018, of December 5, on the protection of personal data and the guarantee of digital rights. The database is kept by the principal investigator and the research team in an Excel (Microsoft) format, protected by password access. An anonymized database was used for the analysis. Before carrying out the survey, internet-based informed consent had to be completed, accepted, and signed. Participation was voluntary, and no compensation was provided to participants.

Results

Survey Outcomes

A total of 1312 respondents were analyzed, with 74.5% (954/1280) being female, 71.0% (915/1289) university graduates, 46.9% (604/1289) having children younger than 15 years of age, 14.0% (180/1287) aged 30 years or younger, 12.4% (159/1287) older than 60 years of age, and 73.7% (948/1287) between 31 and 59 years old. Among the respondents, 85.7% (1124/1312) stated they were regular social network users and shared sociodemographic characteristics (age, children, gender, and education) similar to the total sample analyzed (Table 2), with a predominance of females and university education. Of the regular social network users, 76% (852/1121) had been using social network for more than 5 years, and 35.6% (399/1121) reported seeking information about vaccines on social network. Among these, 39.1% (156/399) used X, 29.6% (118/399) used Instagram, 33.1% (132/399) used Facebook, and 46.6% (186/399) used other social networks. A total of 53.1% (196/369) reported conducting their first vaccine search on social network in 2020, with 84.1% (329/391) stating that their search was related to the COVID-19 pandemic.

Less than 30	5 (22.7)	
30-39	2 (9.09)	
40-49	6 (27.3)	
50-59	7 (31.8)	
60-69	1 (4.55)	
More than 70	1 (4.55)	
Highest educational level completed by the person who rejected vaccination		25
No education or incomplete primary studies	1 (4.00)	
Secondary	3 (12.0)	
High School	3 (12.0)	
Vocational training programs	1 (4.00)	
University	17 (68.0)	
Have you received any type of opinion or comment through social networks? n (%)		1287
Against vaccines	815 (63.3)	
In favor of vaccines	1007 (78.2)	
Do you follow social networks that generate doubts about vaccines?, n (%)	94 (7.28)	1291
Do you follow any social media profile? n (%)		
Against vaccines	99 (7.67)	1291
In favor of vaccines?	479 (37.1)	1290
Have you made any comments on social networks? n (%)		
Against vaccines	31 (2.40)	1289
In favor of vaccines	351 (27.4)	1281

Among the respondents, 66% (850/1287) reported having encountered antivaccine information on social network; of those who received this information, 24.3% (205/845) had doubts about the administration of recommended vaccines, and among those who had doubts, 13.3% (27/203) rejected a vaccine recommended by a health care professional. Among those who rejected vaccines for children, 10 (58.8%) were women, 13 (59.1%) were aged between 40 and 59 years, and 17 (68%) had university degrees; vaccines were rejected for children with an average age of 9.1 years.

A total of 63.3% (815/1287) of the respondents reported having received opinions or comments against vaccines on social networks, and 78.2% (1007/1287) reported having received opinions or comments in favor. In addition, 7.3% (94/1291) reported following social network accounts that generated doubts about vaccines, and 7.7% (99/1291) reported following antivaccine profiles on social network while 37.1% (479/1290) followed provaccine profiles on social network. A total of 2.4% (31/1289) stated they had made a comment against vaccines on social network, and 27.4% (351/1281) reported having made a comment in favor.

Social Network Results

Sentiment Analysis

The analysis revealed the following distribution: 17.37% (83,357/479,734) of posts were classified as “Positive.” A significant portion, 54.44% (261,183/479,734) of posts, were categorized as “Negative.” Neutral sentiments accounted for 28.18% (135,194/479,734). When comparing with a human coder for positive and negative posts on a sample of posts, percent agreement was 75.24%, indicating the classifier had decent surface-level reliability. These findings suggested that the content in posts was likely to be more negative in nature (Table 3). Furthermore, the overall average sentiment was negative, with a result of −1.96 (SD 4.39).

XSL•FO
RenderX

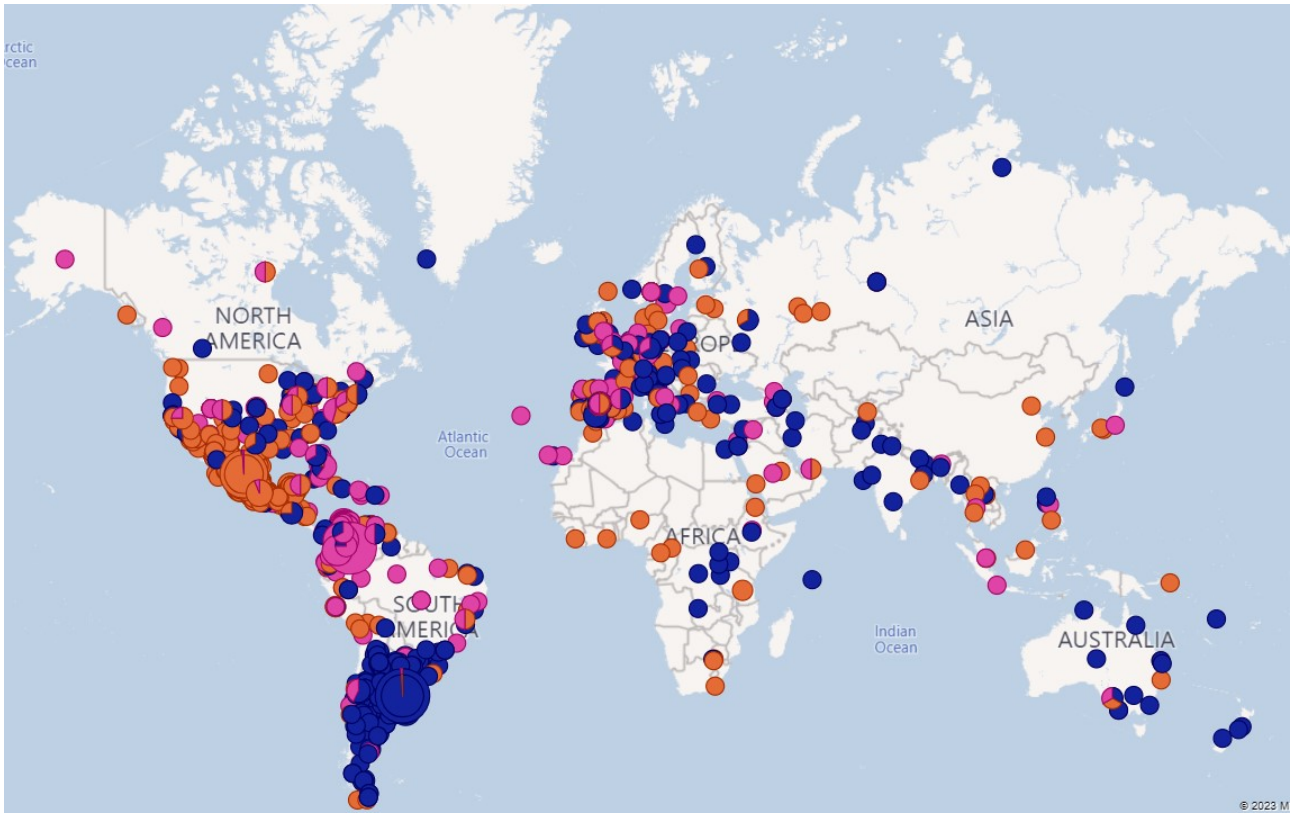

Table . Classification of sentiment (N=479,734).

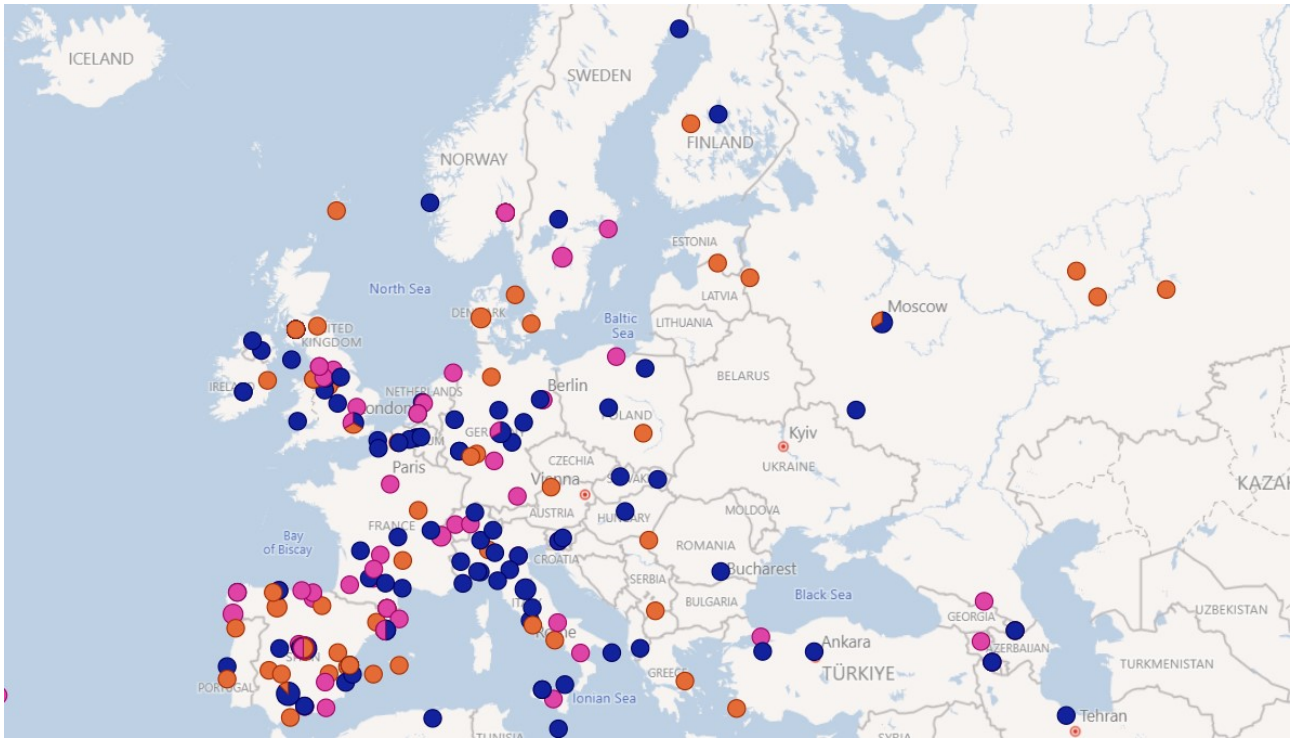
Sentiment	Value, n (%)
Positive	83,357 (17.37)
Negative	261,183 (54.44)
Neutral	135,194 (28.18)
Total	479,734 (100)

Location-Based Analysis



Location-based analysis focused on examining a specific time period in our dataset, that is, April 2021, as shown in Figures 1 and 2; Most posts were from South America (such as Argentina, Venezuela, Colombia, and Mexico) and Europe (mainly Spain). Some posts were from other European countries, such as the United Kingdom and Germany.

Figure 1. Overview of positive (orange), negative (dark blue), and neutral (purple) posts.

XSL•FO
RenderX

Figure 2. Zooming into Europe (mixed sentiment).

We observed a significant concentration of users in regions where Spanish was predominantly spoken. As indicated, these posts originated from South American countries, such as Argentina, Venezuela, Colombia, and Mexico. This trend underscored the Spanish-speaking demographic within these nations. In addition, a notable volume of posts was traced back to Europe, particularly Spain, further demonstrating the Spanish language's influence when retrieving the data, as Spanish keywords were used to retrieve posts.

To gain an insight into the distribution of positive, neutral, and negative posts, further analysis was conducted using data captured during April 2021. The positive, neutral, and negative groups were identified during the social network analysis. Figures 1 and 2 (April 2021) provide a visual overview of the locations. Sentiment analysis revealed regional differences across the geographic distribution of posts. More negative sentiments were predominantly observed in South America, while sentiment in Europe showed a mix of positive, neutral, and negative posts. In contrast, posts from North America exhibited comparatively more positive sentiments. Although the dataset included only Spanish- and Catalan-language posts, the presence of North America in the maps reflects the global reach of these languages, encompassing regions such as Mexico and Hispanic communities in the United States. It is important to highlight that location data were voluntarily self-reported by users, and thus geographic coverage may be incomplete or biased. These findings illustrate the varied landscape of vaccine-related discourse across Spanish- and Catalan-speaking populations during the study period.

Social Network Analysis and Topic Insight

The most prominent group identified was the "isolates" group (Group 1). This group was characterized by individuals who sent original posts without interactions. The predominance of this group suggested that the topics were widely popular and managed to draw a variety of unique and original opinions from a diverse audience.

The groups numbered 3-5 exhibited characteristics of community network shapes intertwined with elements of broadcast. These groups demonstrated high interconnectedness, indicative of frequent and active back-and-forth conversations. At the same time, there was a noticeable amplification of certain accounts within these groups, which pointed to a blend of personal interaction and wider broadcast of information or opinions (Figure 3).

XSL•FO
RenderX

Figure 3. Social network analysis with top 5 groups (April 2021).

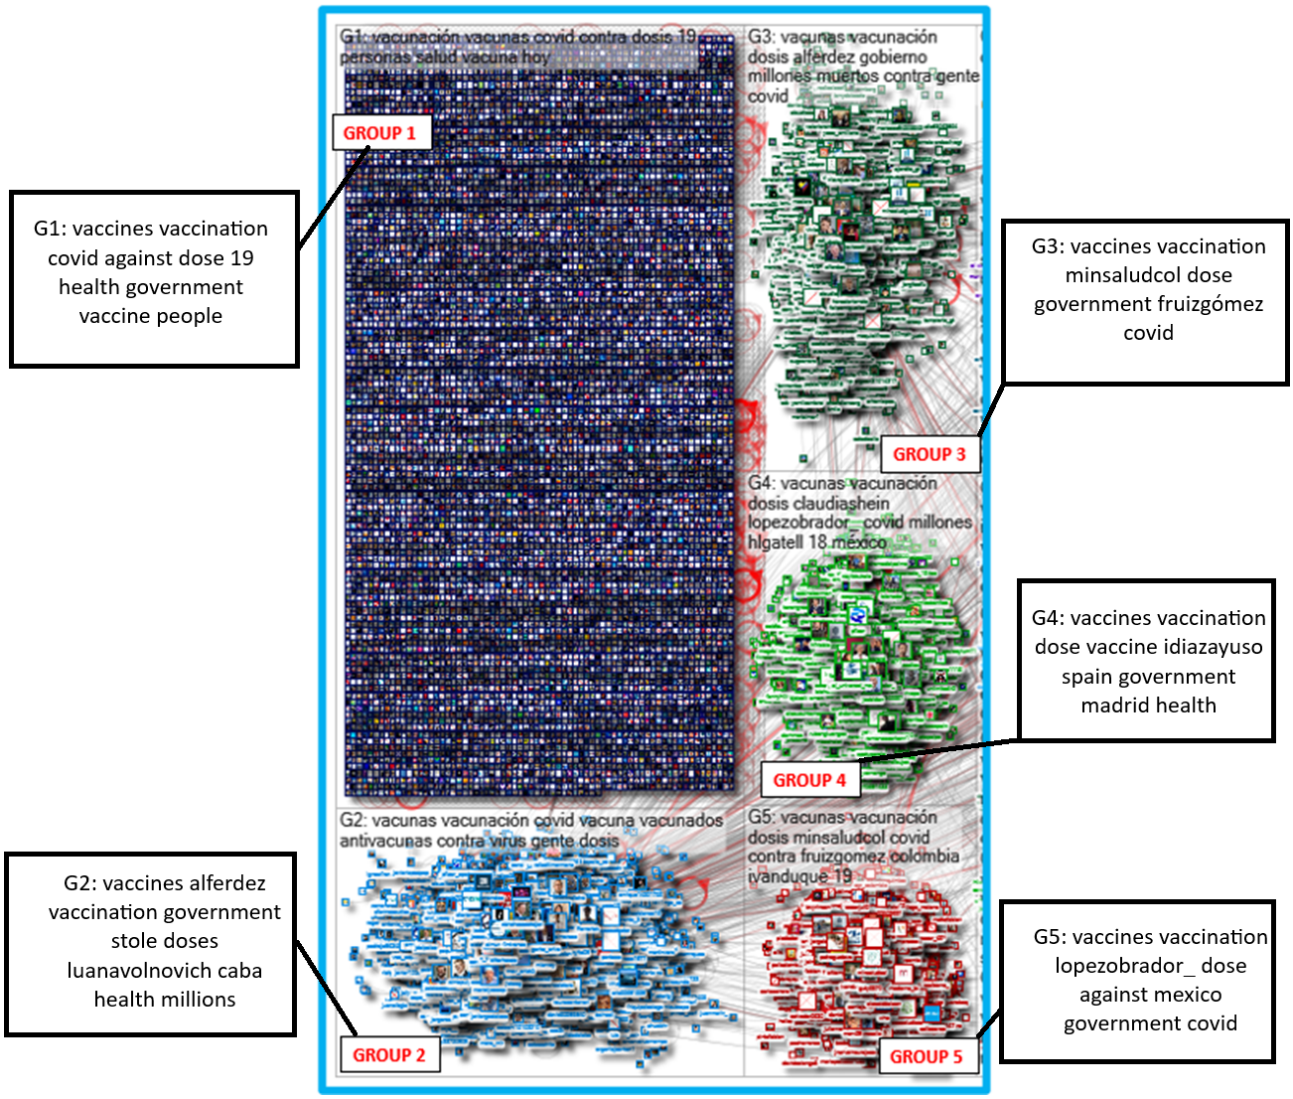


Table 4 provides insight into the top 5 users ranked by betweenness centrality, a metric indicating the extent to which a user acts as a bridge within a network. Alberto Fernández, the former Argentine President, had a very high centrality score. This suggested that he was a central user within the network and was key to information flow despite having fewer followers than global organizations like the World Health Organization (WHO). Furthermore, an ordinary citizen, labeled as a "Member of the Public," ranked third, which highlighted how ordinary users can become influential on social media. User 4, the Pan American Health Organization, held a strong intermediary role despite a modest follower base. User 5, Iván Duque, had a notable influence through his centrality.

Table . Top users ranked by betweenness centrality.

Rank	User	Betweenness centrality	Followers
1	Alberto Fernández (Former President of the Argentine Republic [2019-2023])	127,116,284.117	2,304,550
2	The World Health Organization	48,398,978.460	12,356,193
3	Member of the Public	47,989,441.412	1715
4	The Pan American Health Organization (regional office for the Americas of the World Health Organization	47,361,720.241	430,494
5	Iván Duque (President of Colombia from 2018 to 2022)	39,020,770.895	2,565,413

The following conversation groups on X were analyzed:

XSL•FO
RenderX

1. Group 1: By examining the keywords and network insights, conversations centered around the global response to the COVID-19 pandemic, and they emphasized vaccination efforts. Users discussed the vaccination campaign targeting various groups, particularly older adults, who were among the most vulnerable to the virus.
2. Group 2: Discussions indicated challenges pointing to vaccine theft issues and highlighted the struggles in managing and securing the vaccine supply. There were also discussions on organized strategies and public health initiatives to combat the pandemic.
3. Group 3: Discussions were based on a focused campaign in the State of Mexico (Edomex), and users discussed the scale and nature of the initiative, which was the large-scale distribution of vaccines. There was also a personal, community-centric dimension to the campaign, which emphasized the societal importance of protecting older adults against COVID-19.
4. Group 4: There was a focused narrative on the COVID-19 pandemic, particularly highlighting the vaccination efforts for older adults. Users also referred to the "Chinese vaccines," which implied a specific type of vaccine being discussed. Central themes included the process and challenges of vaccination, the procurement of vaccines, and the scale of the effort.
5. Group 5: The keywords suggested a comprehensive national plan in Colombia to combat COVID-19 through a vaccination campaign. The discussions also noted the well-defined procedure for administering the vaccines. There were also discussions of a targeted approach toward vaccinating older adults, particularly those more than 80 years old, recognizing their vulnerability to the virus. There were also discussions around the involvement of the Colombian Ministry of Health and its officials, including Fernando Ruiz Gómez, in orchestrating and overseeing the public health initiative (Table 5).

Table . Overview of topic keywords (April 2021).

Group	Key themes inferred
Group 1	• Vaccination campaign and logistics • Targeted vaccination for older adults • Scale of vaccination effort
Group 2	• Vaccine mismanagement and theft • Vaccination of priority groups and health care workers • Very Important Person vaccination controversy
Group 3	• Alfredo Del Mazo's administration's role • Nationwide vaccination against COVID-19 • Community focus in vaccination
Group 4	• Chinese vaccines and procurement • Vaccination process and challenges • Health care capacity and response
Group 5	• Comprehensive National Vaccination Plan • Special attention to vulnerable populations • Ministry of Health's involvement

In regard to the sentiment across the groups, it was not possible to quantify an entire group as either positive, negative, or neutral due to the diverse range of conversations taking place.

Discussion

Principal Findings

This study used a dual-methods design by combining a population-based survey in Spain with sentiment analysis of Spanish-language posts on X. Although these 2 components focused on different populations, survey respondents in Spain and global Spanish-speaking social media users, they provided complementary insights. The survey allowed us to identify who engaged with vaccine information on social networks and their characteristics, while the analysis of X offered a broader perspective on the type of content to which these users may be exposed. Given the transnational nature of social media, vaccine-related narratives circulate beyond national borders, influencing public perceptions regardless of their geographical origin. This exploratory approach facilitates a more comprehensive understanding of the potential impact of social networks on vaccine information access and perception. It is well-known that social media platforms are sources of health information and can have considerable influence on health decision-making [36]. In our study, we observed that a significant portion of the surveyed population in Spain reported frequent engagement with vaccine-related content on social media platforms, and 66% (850/1287) of respondents reported encountering antivaccine information. Concurrently, our analysis of Spanish- and Catalan-language posts on X identified that 54.44% (261,183/479,734) of posts were categorized as expressing negative sentiment. It is important to note, however, that negative sentiment does not necessarily indicate antivaccine attitudes. Such messages may include expressions of concern, criticism of public health measures, or institutional communications reporting unfavorable epidemiological data [37,38]. Previous research has shown that negative sentiment in vaccine-related posts can reflect a wide range of perspectives,

XSL•FO
RenderX

including anxiety about side effects, mistrust in institutions, or reactions to the broader pandemic context. These findings highlight the importance of interpreting sentiment classifications with caution, as negative sentiment may encompass diverse forms of content that are not inherently opposed to vaccination. A large-scale analysis of 9,352,509 English-language posts from 2020 identified that only 2.49% were explicitly antivaccination. However, the same study reported an increase in antivaccine sentiment on social media following the initial rollout of COVID-19 vaccines [21]. Similarly, another study analyzing English tweets from the United Kingdom and the United States between March and November 2020 reported negative sentiment in 27.95% and 30.57% of posts, respectively [24]. These data reinforce the need for nuanced interpretation of social media discourse, as platforms like X are both a source of verified information and a space where conspiracy theories and misinformation can also circulate [33,39].

In our analysis of social networks, we identified relational patterns within the studied groups on the topic of vaccination. Specifically, groups numbered 3-5 exhibited characteristics of community network shapes intertwined with elements of broadcast. These groups demonstrated high interconnectedness, indicative of frequent and active back-and-forth conversations, mixing positive, negative, and neutral sentiments. A previous publication shows that interaction between antivaccine groups and undecided groups could facilitate vaccination hesitancy in the undecided due to exposure to antivaccine messages [15].

The analysis of each group allows us to see the key themes of the conversations, which can be useful for detecting the population's concerns and creating vaccination campaigns aimed at combating misinformation or doubts about vaccination, potentially generating new evidence in community interventions as described in previous publications [13,16,22,24,40]. Some of these publications propose a method to counteract fake news, which involves quickly detecting and directly addressing it as it arises [33,39]. The analysis of topic words and key themes in our study allowed us to group the predominant themes of the 5 study groups, which were (1) vaccination efforts for the COVID-19 pandemic, (2) vaccine theft issues and struggles in managing and securing the vaccine supply, (3) a campaign in the State of Mexico, (4) vaccination efforts for older adults, and (5) a vaccination campaign in Colombia to combat COVID-19. We hypothesize that the topic words and themes may be influenced by the demographic distribution of posts from Spanish-speaking countries, primarily in South America. Another study also analyzed the themes of vaccine-related tweets on X in the Australian population, primarily detecting three themes, including attitudes and actions toward COVID-19 and its vaccination, infection control measures, and confidence in COVID-19 vaccine trials, alongside baseless claims, conspiracy theories, complaints, and misconceptions about various measures against COVID [23]. Another study develops algorithms for automatically classifying a large number of vaccine-related tweets into 3 classes, such as provaccine, antivaccine, and neutral [16].

The geographical location of the messages and the analysis of positive, negative, and neutral sentiments are useful tools for generating vaccination campaigns and detecting groups with higher hesitancy [24]. In our study, we found that more posts classified as negative appeared to derive from South America, with a mix in Europe, and more positive posts in North America. In Spain, positive and neutral posts predominated, which aligns with Spain generally showing good vaccination coverage and acceptance among the population [41]. However, given the high level of technological connectivity in today's society, a tweet or post generated in North or South America could influence the Spanish population.

To combat vaccine hesitancy, it is essential to implement interventions that address the infodemic, such as promoting digital literacy and equipping the public with skills to critically evaluate digital media content [20,42]. Social media users often struggle to distinguish accurate information from misinformation, as they may be influenced by nonscientific influencers or fear-based narratives rather than validated scientific evidence [42]. Policy makers and public health care professionals must consider the adverse effects of social media on vaccine perceptions. Strategies to reduce vaccine hesitancy should include monitoring emerging trends, engaging with social media communities, and providing clear, evidence-based information [43]. Collaborating with trusted social media influencers to disseminate accurate health messages can also be an effective approach to counteract misinformation and build public trust [44].

A limitation of our study is that the "Social Network Analysis and Topic Insight" focused specifically on the X network in April 2021, so our findings may not be applicable to other time periods. Future research could extend the analyzed time periods and examine X discussions in different locations. One limitation of our sentiment analysis is the use of fixed sentiment categories (positive and negative). While this approach is widely used, it may not capture the full emotional spectrum of posts related to vaccination, such as feelings of sadness, anger, or fear. Future studies could expand the emotional categories used in sentiment analysis to provide a more comprehensive understanding of the diverse emotional responses to vaccine-related content on social media. A further limitation lies in the use of "self-reported" user bias, as users do not always specify their correct place of residence. In addition, certain accounts repeatedly tweeted and dominated discussions; future research could examine their role and impact within our dataset. Finally, we acknowledge that the selection of keywords may introduce bias in data collection. Future research should refine keyword selection strategies to improve representativeness across diverse Spanish-speaking regions and assess potential biases arising from linguistic variations.

One of the limitations of the survey was the inherent recruitment bias associated with the internet-based survey method, which restricted participation to individuals with internet access. However, given that 96.1% of Spanish households have internet access and 85% of Spaniards are users of social networks [45,46], the reach of our survey remains substantial. Another possible limitation is potential respondent repetition, although we anticipate minimal impact on the final results because of the expected low rate of repetition. In addition, our sample skewed toward women and people with a university education, which could limit the interpretation and generalization of our study to

XSL•FO
RenderX

the broader population. Finally, reaching the antivaccine population posed challenges, as interactions with these groups are difficult. To mitigate eventual bias deriving from this, in our sample size calculation, we considered that the proportion of antivaccine responses would be much lower than the proportion of provaccine responses. Despite these limitations, our study provides valuable insights into opinions about vaccines, but caution is warranted in extrapolating findings to the entire population.

Conclusions

Our study highlighted that a significant proportion of the surveyed population encountered antivaccine content on social networks. There was a notable presence of posts categorized as negative on the social network X, particularly from South America. These results underscore the need for nuanced interpretation of social media sentiment, as negative posts may reflect diverse concerns, including public health measures, vaccine safety, or broader pandemic-related issues. The integration of sentiment, thematic, and geolocation analyses may offer useful insights into the evolving nature of vaccine-related discourse on social media. While exploratory in nature, this approach can support public health efforts to monitor social media narratives and adapt communication strategies accordingly. Although further research is needed, our findings suggest the potential value of actions, such as improving digital health literacy, supporting critical appraisal of social media content, and providing timely, evidence-based information in response to misinformation trends. Public health institutions may also benefit from more direct engagement with social media communities to build trust and promote informed dialogue. These findings provide actionable insights that can inform ongoing digital surveillance, support the design of targeted public health messaging, and enhance risk communication strategies tailored to specific populations and critical moments. Recognizing the evolving nature of social media platforms, including Twitter's recent rebranding to X, adapting these approaches will be essential for maintaining effective vaccine-related communication in dynamic social media environments.

Acknowledgments

Data collection would not have been possible without the collaboration of the MC-MUVA work group (Rebecca Oglesby, Merce Font Arbó, Lidia Sanz Borrell, Mireia Biosca Pàmies, Marta Pifarre Ortiz, Sara Martí Martí, Daniel Gros Esteban, Laura Guix Cliville, Noelia Diaz Charles, Silvia Prado Muñoz, Susana Perez Osuna, Mercè Giribet Folch, Magda Riera Veciana, Carles Gatius Tonda, Laura Seoane Barbosa, Pilar Serra Solans, Míriam Poblet, M. Abstract

Background: Vaccine information and misinformation are spread through social media in ways that may vary by platform. Understanding the role social media plays in shaping vaccine preferences is crucial for policymakers and researchers.

Objective: This study aims to test whether social media use is associated with changes in vaccine preferences during the COVID-19 pandemic in New Zealand, and whether trust in sources of information has a moderating role.

Methods: Our data consist of a balanced panel of 257 web-based respondents in New Zealand in August 2020, October-November 2020, and March-April 2021. We use a novel approach with stated choice panel data to study transitions between different vaccine preference groups. We analyze the associations between these transitions and social media use. We classify respondents as resistant (never chose a vaccine), hesitant (chose a vaccine between 1 and 5 times), and provaccine (chose a vaccine 6 out of 6 times) in each wave of data.

Results: We found a positive or neutral association between social media use and vaccine uptake. Facebook, Twitter (pre-2022), and TikTok users who are provaccine are less likely to become hesitant or resistant. Facebook and Instagram users who are hesitant are more likely to become pro. Some social media platforms may have a more positive association with vaccine uptake preferences for those who do not trust the government.

Conclusions: The paper contributes to the wider literature, which shows social media can be associated with reinforcing both pro and antivaccination sentiment, and these results depend on where individuals get their information from and their trust in such sources.

Introduction

The COVID-19 pandemic has had substantial global impacts, with over 6 million deaths reported to the World Health Organization to date, alongside other impacts such as 5% - 20% of cases leading to long COVID and widespread economic disruption [1-3]. Vaccination is a vital tool for combating the pandemic, both now and into the future [4]. Despite the clear benefits of vaccination against COVID-19 and other diseases, many people are hesitant or resistant [5-7]. A rapidly emerging body of literature focuses on the characteristics associated with COVID-19 vaccine uptake [7-10]. Indeed, it is important to use data from this period to study what influences vaccination preferences, given the unprecedented global attention on COVID-19 vaccination, the speed of vaccine development, and the potential for future pandemics [11]. Given worries that vaccination hesitancy could be on the rise, it is doubly important to learn from the COVID-19 pandemic [12].

The role of information, who provides that information, and trust in that information have all been shown to be key factors in vaccination uptake [6,13]. Social media platforms are increasingly used as a source of information [14]. The nature of social media means that information sources and types vary greatly, with everything from conspiracy theories to scientific information. Both types of information have been shown to disseminate in a relatively similar manner, with some differences

XSL•FO
RenderX

by platform [15,16]. There is evidence that users tend to seek out information that accords with their pre-existing beliefs, regardless of whether it is factual or not [17]. Thus, users end up in echo-chambers reinforcing their own beliefs regarding vaccination and other socially important topics, particularly when issues are controversial [16,18,19]. Indeed, prior work suggests antivaccine sentiment generates more engagement than provaccine sentiment [20] and that exposure to misinformation can decrease intent to vaccinate [12,21,22]. However, there are still relatively few papers that use panel data to investigate the relationship between social media use and vaccine preferences, and our understanding of this relationship is still limited.

A range of studies use survey methods to investigate the association between social media use and willingness to vaccinate against COVID-19. These studies show a mixed picture. Several multi-national studies of European nations and the United States of America show either a negative or nonsignificant association between social media and willingness to vaccinate, depending on the country [23,24]. Similarly, Park et al [8] conducted a survey in the United States and found the lowest vaccine acceptance levels among those who rely on social media for information. In another USA-based survey, Al-Ugdah et al [25] find a positive association between social media users and willingness to vaccinate, but the opposite when no medical or government source of information is used alongside it. Bendau et al [26] found that Germans who report the use of social media to garner information on vaccination have higher acceptance than those who do not. Wang et al [27] report a similar finding in China. These studies all use cross-sectional surveys, but do not have a panel sample recording changes over time.

There are fewer studies using panel surveys, tracking changes in intention to vaccinate and their relationship with social media use. Romer and Jamieson [28] conducted a panel survey in the United States in March and July 2020. They find that social media use is associated with conspiracy beliefs and vaccine resistance, with underlying political ideology playing a key role. Beliefs and preferences around health behaviors were relatively stable over the survey period. In their panel survey, Theocharis et al [29] find that COVID-19 conspiracy beliefs change over time. Twitter reduces the propensity to believe in this conspiracy, whereas other platforms (Facebook, YouTube, Messenger, and WhatsApp) increase these beliefs. They do not look specifically at intention to vaccinate.

In this paper, we investigate whether social media use is positive or negative for COVID-19 vaccination uptake, both on average and in terms of polarization over time. We conducted a web-based stated preferences panel survey of New Zealanders over 3 waves between August 2020 and April 2021, while vaccines were being developed, approved by regulators, and initially rolled out. New Zealand provides an interesting case study due to the high levels of government trust at the time [30-32], Thus, New Zealand has the potential to show a best-case scenario for the impact of social media on vaccine uptake.

We collected data on respondents' social media use over the previous 6 months, by platform, in the third survey wave. This 6-month period roughly covers the time between the first survey wave and the third. To test for polarization, we model transitions between types of vaccine preferences between waves using a Logit model, to test whether social media use is associated with a change or a reinforcement of earlier choices. We then model the association of social media use with likely vaccine uptake overall (positive or negative on average) using a pooled partial proportional odds (PPO) model with time fixed effects [33]. Finally, we test how trust in government, friends, and family could moderate the effect of platform use. We contribute to the literature by furthering our understanding of the potential role of social media and trust in information on shaping vaccine preferences. Additionally, we demonstrate a novel approach to analyzing stated preference data, we use panel data to explore changes over time, and we examine preferences during the COVID-19 pandemic in New Zealand—an informative context to study the interactions between social media use, trust in information, and vaccine preferences.

Methods

Data

We use the New Zealand data from Hess et al [7], which is a web-based stated choice survey on COVID-19 vaccines, undertaken on 20 - 29 August, 2020 in the case of New Zealand. Additionally, we repeated the survey for the panel from 26 October to 18 November, 2020 (wave 2) and 23 March to 24 April, 2021 (wave 3). This element of the research design was important to be able to track changes over time. The panel was recruited using the Qualtrics survey company, and was initially representative of the New Zealand population of 18 years and older for age and gender (reweighting as needed for analysis, described at the end of this section). Qualtrics recruited into the survey from a pool of potential New Zealand-based participants who are available for the purpose of collecting representative data in web-based surveys, with a small financial incentive. We checked the survey responses across the panel, and there were no discernible signs of poor quality responses (eg, very short completion time).

The time period of the 3 waves captures a key moment for information gathering and preference formation regarding vaccines. Development and testing were being undertaken during waves 1 and 2. The Pfizer-BioNTech vaccine was approved by the United States Food and Drug Administration in December 2020, with Medsafe in New Zealand following on 3 February 2021. As the only vaccine initially offered in New Zealand, the rollout of Pfizer-BioNTech to a select group had begun by wave 3, with more advanced rollouts underway in other countries.

Additionally, over this time period, trust in the government increased and was high due to their strong lockdown policies, which were successful in eliminating community COVID-19 cases within New Zealand [30-32]. Demonstrating this high support, Prime Minister Jacinda Ardern's Labor Party won re-election in October 2020, increasing their vote share to the highest ever for a single political party since New Zealand introduced its proportional representation electoral system in 1996, at 50% of the vote.

XSL•FO
RenderX

The main part of the survey is a stated choice survey, using a technique often called a discrete choice experiment [34]. Respondents were presented with 6 hypothetical, but realistic, choices regarding a COVID-19 vaccine. In each choice, respondents were asked to choose their preferred option out of 2 vaccines (each available as paid or free with a wait time) and no vaccine, giving them 4 vaccine choices and one no vaccine. The vaccines varied by risk of infection, serious illness, protection duration, mild or severe side effects, and population coverage. We used the Qualtrics web-based survey platform. It randomly assigned each respondent one of 6 blocks of choice sets. Respondents saw the same block of questions as initially assigned to them in each survey wave.

The choice sets were generated using a D-efficient design [35] from the NGene software package (ChoiceMetrics) [36]. They were calibrated such that an overall view of each respondent's vaccine preferences over key vaccine attributes could be established, within credible ranges. Thus, they give us an overall view of COVID-19 vaccine preferences, rather than asking about specific vaccines that were in development. Each of the 4 question blocks is balanced such that a raw count of the number of vaccines chosen out of 6 is roughly comparable between respondents. For more details on the questions, see Hess et al [7].

Discrete, stated choice surveys are widely used in health due to their effectiveness in providing an accurate and fine-scale measure of individuals' preferences [7,34]. While stated survey measures of sentiment, willingness, or intention to vaccinate are also valid approaches used in the literature (as covered in the introduction), the strengths of a discrete choice experiment mean it is highly suited to understanding vaccine preferences within a specific case study using hypothetical but realistic vaccine options. This is particularly important as the vaccines were still under development and their attributes were not clear. Hence, we could also not measure real vaccine uptake during this period [22].

For each wave, we sum the number of times respondent i selects a vaccine option across the 6 choice scenarios. We then classify individuals into 3 vaccine uptake categories, which we denote as resistant (vaccine chosen 0 times), hesitant (vaccine chosen 1 to 5 times), and provaccine (vaccine chosen 6 of 6 times). As noted in the previous paragraph, there may be some differences between the 4 choice blocks that could drive different counts between individuals, but these should not be significant and are unlikely to affect our classification of respondents into 3 categories (this classification approach reduces the influence of any minor measurement error across the blocks). Respondents also saw the same choice block in each wave, so differences between waves, within individuals, are not due to changes in questions.

In the New Zealand survey of Hess et al [7] in wave 3 only, we asked about the frequency of social media use, by platform, in the last 6 months. This period roughly equates with the time between the first and third survey waves, so that we can measure the association between use and changes in vaccination uptake preferences between survey waves. Platforms included are Facebook, Instagram, Twitter, and TikTok. We use dummy coding, with anyone using the platform at least once a week being coded as a user.

We asked participants about their trust in various sources for information about COVID-19 vaccines. We test their moderating effect on social media and vaccine uptake. They were measured on a 5-point Likert scale, and we coded them as dummy variables of trust (1) versus neutral or distrust (0).

We pool our data across the 3 waves, including social media use by type, a rich set of covariates, and time fixed effects. The original wave 1 sample included was representative by age and gender; however, due to attrition, the wave 3 sample needs some reweighting. We reweight for all analyses on the basis of age, gender, and ethnicity from the 2018 census [37,38]. We drop 110 observations with missing data on the variables we use in the modeling. As we collected social media use in wave 3 only, we are left with a balanced panel across the 3 waves of 257.

Ethical Considerations

This project was granted ethics approval for research by the Waikato Management School Ethics Committee (application WMS 20/68). The panel was recruited using the Qualtrics survey company, and respondents were provided a small financial incentive by Qualtrics to participate in the sample. Participants provided their informed consent to participate in the study and had the option to withdraw their data at any time. All data were anonymized by Qualtrics before being sent to the research team to protect the privacy and confidentiality of our research participants.

Empirical Modeling

We are interested in understanding three main points from the data as follows: (1) the association between social media use (by platform) and an individual becoming less (or more) provaccine over time; (2) the overall association of social media use (by platform) with likely vaccine uptake, and (3) the moderating influence of trust in information sources and vaccine uptake.

To understand the first point, we estimate simple Logit models for each transition between waves. This parsimonious modeling approach allows us to estimate the association between social media use and an increase/decrease in likely vaccine uptake over time, at an individual level. Our dependent variable is a binary indicator Lijk=1 for when individual i transitioned to a lower vaccine uptake group between waves j and k, and Hijk indicating if individual i transitioned to a higher vaccine uptake. We include the full set of control variables. We model the transitions separately for the different starting groups in wave j because these groups are fundamentally different from each other. For example, we model Lijk for provaccine individuals, for each wave. This allows us to understand whether social media is associated with staying provaccine or becoming less provaccine between waves j and k. If we had not separated these groups out, we would have implicitly treated transitions from being provaccine to hesitant the same as moving from hesitant to resistant.

For the latter 2 points, we estimate a PPO model [33] on the ordinal dependent variable of stated vaccine uptake of resistance

XSL•FO
RenderX

through to provaccine. This model can give us an overall estimate of the association between social media platforms and vaccine uptake. However, it will not give us as clear a picture of transition over time as the Logit approach outlined above.

The PPO is a specific case of a generalized ordered logit (gologit). It allows us to take into account the ordinal nature of our outcome variable, but relax the proportional odds assumption of the more commonly used ordered logit, when needed [39,40]. The proportional odds assumption states that if we estimate a series of cumulative logit models by successively collapsing the ordinal variable into a binary variable (with different cutoffs), the odds ratios for each regressor will be equal across all models (within the limits of random error). When this assumption is violated, ordinal logit models may produce misleading and biased results [40]. Brant [41] developed a test to determine whether the proportional odds assumption holds for a set of variables. In our case, we find the proportional odds assumption to be violated for several covariates and the overall model. Hence, the PPO model allows us to relax the proportional odds assumption when needed, but keep it for the covariates where it is not violated.

An alternative model we could have estimated, which also does not require the proportional odds assumption to hold, is the multinomial logit model [39]. This model runs a series of logit regressions on every possible binary combination of the categorical variable (in our case, {1 vs 2, 1 vs 3, 2 vs 3}). However, this approach fails to account for the inherent ordering of Uit and computes a number of unnecessary parameters [40].

Using maximum likelihood, our PPO model estimates the probability that individual i in wave t is resistant, hesitant, or pro, represented by Uite {1,2,3}, respectively:

$$P(Uit>k)=\exp(\alpha k+Xit\beta 1k+Zit\beta 2)1+[\exp(\alpha k+Xit\beta 1k+Zit\beta 2)],k=(1,2).$$

In our case, we can think of the PPO model as essentially 2 sets of logits, modeling the probability of being in categories 2 and 3 over 1 for the first set of coefficients (k=1), and category 3 over 1 and 2 for the second set of coefficients (k=2). Of course, both logit models are estimated simultaneously, and both are used to calculate predicted probabilities of being in any given category, as represented in the above equation. The coefficients β1k for covariates Xit vary over k. The coefficients β2 for covariates Zit do not vary over k when they do not violate the proportional odds assumption, reducing the number of coefficients to estimate. Covariates are placed into either Xit or Zit, depending on the results of Brant tests. These include time-invariant variables, such as social media use, and wave time fixed effects.

To investigate our aim (2) (stated above), we estimate a separate PPO for each social media platform, plus the full set of controls. For aim (3), we interact social media use with trust in different sources of information on vaccines (friends or family, the government, and social media).

Results

Descriptive Statistics

We start by presenting summary statistics in Table 1 for the variables we use in our modeling (pooled across the 3 waves). In terms of social media use, most of the sample uses at least one social media platform out of the 4 we questioned them on (188/257, 73.2%). A majority of respondents use Facebook (177/257, 68.9%), with use of Instagram, Twitter, and TikTok being significantly lower at 30.4% (n=78), 15.2% (n=39), and 7% (n=18), respectively. Most respondents trust the government (199/257, 77.4%) and a minority trust their friends and family (84/257, 32.7%) as sources of vaccine information. As discussed in the Data section, our New Zealand sample is an informative context to study vaccine preferences, given the relatively high levels of trust in government, as COVID-19 vaccines were rolled out. Moreover, most respondents distrust social media generally (195/257, 75.9%) as a source of vaccine information. Across the 3 waves, we classify 76.1% (587/771) of responses as belonging to the provaccine uptake group, 18.3% (141/771) of responses as belonging to the vaccine-hesitant uptake group, and 5.6% (43/771) of responses as belonging to the resistant uptake group.

[b]This work was undertaken before the change of ownership and approach at Twitter in 2022. Most users of less-common social media platforms in our sample (TikTok, Twitter and Instagram) also used Facebook. Only 6% of social media users did not use Facebook.

[c] This variable is measured in New Zealand dollars (NZ $). At the modal time this variable was measured (August 25, 2020), the exchanged rate to US dollars (US $) was NZ $1 = US $0.65,

In Figure 1, we use a Sankey flow diagram to visually depict transitions between vaccine uptake groups across the 3 waves. Evidently, there are significant movements between vaccine uptake groups over time, particularly for the hesitant. Overall, we see movement away from hesitant by wave 3, towards provaccine and resistant. There is also a considerable proportion of respondents who remain stable in their vaccine uptake group membership across the 3 waves. Multimedia Appendix 1 contains the transition matrices.

XSL•FO
RenderX

Figure 1. Sankey diagram of individual transitions between vaccine uptake groups across waves.

Transition Models

In Table 2, we present the marginal effects at the means (MEMs) of social media use on the probability of provaccine individuals moving to a lower vaccine uptake group. These marginal effects show the change in probability for the dependent variable occurring when all other variables are set at their sample means. The first column shows the transition between waves 1 and 2, and the second column represents the transition between waves 2 and 3. Each row represents the MEMs from a model with a full set of controls, and one type of social media platform (or all social media platforms in the case of the first row). The full logit results, including controls, are in Multimedia Appendix 1.

Table . Marginal effects at the means (MEMs) of social media use on the probability that provaccine individuals decrease uptake between waves. Cluster robust SEs in parentheses. Results have been reweighted on age, gender, and ethnicity.

MEMs for platform use	Dep. variable: decrease in uptake	
	Waves 1 to 2 (n=194), mean (SE)	Waves 2 to 3 (n=191), mean (SE)
Social media use	−0.0187 (0.0678)	−0.109 (0.0879)
Facebook use	0.0161 (0.0583)	−0.156 (0.0829)[a]
Instagram use	−0.0484 (0.0549)	−0.132 (0.0827)
Twitter use	−0.164 (0.0566)[b]	−0.145 (0.0777)[a]
TikTok use	−0.151 (0.0548)[b]	−0.144 (0.0809)[a]

[a]$P<.1$

[b]$P<.01$

We can see that Twitter and TikTok are associated with a significantly lower probability of provaccine individuals decreasing uptake between waves 1 and 2 (P<.01). Twitter users are 16.4 percentage points less likely to decrease uptake, and TikTok users are 15.1 percentage points less likely. The MEMs are similar in size for these 2 platforms for the waves 2 to 3 transition (however, the MEMs are only marginally significant). The MEMs are significantly stronger for the waves 2 to 3 transition for general social media, Facebook, and Instagram use. For the waves 2 to 3 transition, provaccine Facebook users are 15.6 percentage points less likely to decrease vaccine uptake (significant at the 10% level). We do not estimate this model for the vaccine-hesitant group moving to resistant, as there are too few such transitions.

We estimate the increase in uptake from hesitant in Table 3. We find statistically significant MEMs of social media use on the probability of positive changes in uptake for the waves 1 to 2 transition. Hesitant social media, Facebook, and Instagram users are 29.6, 23.4, and 45.3 percentage points more likely to increase uptake (respectively) between waves 1 and 2. We find no significant MEMs for the waves 2 to 3 transition. We do not

XSL•FO
RenderX

include any other transition models due to sample size and rarity of transitions. For example, only 4 individuals went from hesitant to resistant between waves 1 and 2, making it impossible to model these transitions using our suite of covariates.

Table . Marginal effects at the means (MEMs) of social media use on the probability that vaccine-hesitant individuals increase uptake between waves. Cluster robust SEs in parentheses. Results have been reweighted on age, gender, and ethnicity.

MEMs for platform use	Dep. variable: increase in uptake	
	Waves 1 to 2 (n=53), mean (SE)	Waves 2 to 3 (n=52), mean (SE)
Social media use	0.296 (0.105)[a]	0.108 (0.157)
Facebook use	0.234 (0.112)[b]	0.0694 (0.151)
Instagram use	0.453 (0.150)[a]	−0.101 (0.266)
Twitter use	0.0264 (0.131)	0.166 (0.179)
TikTok use	0.107 (0.200)	0.0315 (0.265)

[a]$P<.01$

[b]$P<.05$

Partial Proportional Odds Model Results

In Table 4, we present the coefficients for the full PPO results of our base models with pooled data, wave fixed effects, and no interactions. Each pair of columns shows a separate model, varying only by the social media platform dummy included in the model. The first set of columns, (1), is social media use of the specified platform. The left column, labeled 1 versus 2, 3, models being hesitant or provaccine, over being resistant. Hence, a positive coefficient indicates a more provaccine orientation (more likely to be hesitant or provaccine than resistant). The right column, labeled 1, 2 versus 3, models being provaccine, over being hesitant or resistant, with positive coefficients again indicating a more provaccine orientation. Where coefficients are missing, these have been restricted to being the same across both columns, as the proportional odds assumption is not violated. As described in the Methods section, our modeling approach allows us to relax the assumption that covariates have the same impact on preferences across different transitions. Moreover, our results in Table 4 show how social media use and a range of individual characteristics correlate with our novel vaccine preference groupings derived from discrete choice experiment data.

XSL•FO
RenderX

Table . Full partial proportional odds (PPO) modeling results with time fixed effects, excluding interactions. Each pair of columns represents a separate model, varying only by type of Social media user, in the column heading. Cluster robust SEs in parentheses, clustered at the individual level. Results have been reweighted on age, gender, and ethnicity. 1 versus 2, 3 shows the model predicting the likelihood of being 2 (hesitant) or 3 (pro), over 1 (resistant), where a positive number shows more likely to be in 2 or 3. No coefficient in 1, 2 versus 3 means the model is restricted to assume the same coefficient across both columns, as the proportional odds assumption is not violated for that variable. Wave FE (fixed effect) is a fixed effect, coded as a dummy variable for that wave.

	Dependent variable: vaccine preference, where resistant is 1 and pro is 3

[b]$P<.01$.

[c]$P<.1$

[d]$P<.05$

Looking across the models, we find that Instagram and Twitter use have a statistically significant positive relationship with vaccine uptake. On the other hand, at least one of the 4 types of social media, Facebook and TikTok use, did not have significant effects. We present the MEMs for social media of these models in Table 5. Here, we see highly statistically significant associations for Instagram and Twitter. Specifically, Instagram is associated with an 11.8 percentage point decrease in the likelihood of being resistant and a 20.3 percentage point increase in the likelihood of being provaccine. The direction is the same for Twitter, albeit with lower marginal effects. It is worth noting again that Twitter and TikTok use is relatively uncommon in our sample (Table 1).

In terms of demographic controls in Table 5, we see that income has a positive and significant association with vaccine uptake. University education, age, and gender do not have a statistically significant association with uptake level. Māori or Pacific ethnicity has a negative association with vaccine uptake, at the 5% or 10% level. Towards the bottom of Table 4, we see that the survey wave fixed effects have little predictive power on vaccine uptake. Wave 3 is associated with a lower chance of being vaccine resistant, with significance at the 10% level for 3 of the 5 models.

XSL•FO
RenderX

Table . Average marginal effects (marginal effects at the mean) of social media use on being in different vaccine uptake categories (from the models in Table 5). Cluster robust standard errors in parentheses, calculated using the delta-method. Results have been reweighted on age, gender, and ethnicity.

Platform	Resistant, mean (SE)	Hesitant, mean (SE)	Pro, mean (SE)
Social media	−0.0120 (0.0140)	−0.0362 (0.0408)	0.0481 (0.0545)
Facebook	−0.0112 (0.0134)	−0.0338 (0.0396)	0.0450 (0.0527)

[b]$P<.05$

Trust Interactions in PPO Models

Next, we look at the trust variables. For the base models in Table 5, we see that the coefficient on trust in government for information about vaccines is positive and strongly statistically significant, as expected. Trust in family or friends for vaccine information has a negative but statistically insignificant relationship with uptake, except for the Instagram model, where it is negative and significant for the 1 versus 2, 3 component of the model. We exclude distrust in social media from the model as it leads to within-sample predictions of negative probabilities for a handful of observations (a drawback of PPO models [40]).

Next, we interact with trust in 2 key information sources (government, and friends and family) on vaccines, with social media type in our base PPO models. This analysis is to test whether trust in information sources has a mediating role in how social media use is associated with vaccine uptake.

We might expect that social media use will be associated with a higher likelihood of vaccine uptake for those who trust the government for vaccine information (compared with not trusting), given the use of social media by the government to inform the public about COVID restrictions. Finally, we expect social media users will be less likely to take the vaccine if they trust their friends or family for vaccine information (compared with not trusting), given that friends or family may share vaccine information on social media and are a less reliable source of information. To test these hypotheses, we follow the same approach as before and re-estimate the models from Table 5, with just the interaction of interest. We present the MEMs for these interactions in Table 6.

Let us first consider general social media use and trust in government, in the top left of the table. We see that social media use for those who trust the government is associated with a 4.7% lower probability of being resistant, which is statistically significant at the 5% level. However, none of the other marginal effects is significant, nor is the difference between the marginal effects for those who trust the government for vaccine information and those who do not. There is a similar result for Facebook users.

[c]$P<.05$

[d]$P<.01$

Instagram, Twitter, and TikTok users have higher probabilities of being pro and lower probabilities of being hesitant or resistant, for both individuals who trust the government and those who do not. The MEMs of social media use on those who trust the government and those who do not are counterintuitive. For example, Twitter use is associated with a 11.7 percentage point decrease in the probability of being resistant, for those who do not trust the government. On the other hand, Twitter use is associated with only a 3.9 percentage point decrease in being resistant for those who do trust the government. This is a statistically significant difference. Instagram and TikTok use shows largely similar patterns to the Twitter example mentioned here. Thus, Twitter, Instagram, and TikTok use is associated more positively with vaccine uptake for those who do not trust the government, compared with those who do trust the government.

The right side of Table 6 shows the MEMs for interactions between social media use and trust in friends and family. We might expect those who trust friends and family for vaccine information to be more susceptible to misinformation on social media. We see this for social media users in general in the top rows; social media users who trust friends and family are more likely to be resistant and hesitant, and less likely to be pro, at the 10% level. This finding is true for Facebook users as well. There are no significant differences for Instagram or TikTok users. However, we see the opposite for Twitter users. Twitter users who trust their friends and family are more likely to be pro and less likely to be hesitant compared with those who do not trust their friends and family, again at the 10% level of significance.

Discussion

In this paper, we have demonstrated a novel approach to analyzing stated preference data. Specifically, we categorize individuals as resistant, hesitant, or pro, based on the number of times they chose a vaccine option in a set of 6 stated choices. Our stated choice method (discrete choice experiment) is a well-established means of understanding individual vaccine preferences; our means of analyzing such data adds another method to understanding vaccine orientation. We investigate the association between individual choices and social media use over time using both a Logit and PPO model, and we use the PPO model to understand the moderating role of trust in sources of information. Our data were collected during vaccine development and initial rollout, between August 2020 and April 2021. Our context in New Zealand had a high trust in the government at the time.

We find a positive or neutral association between social media use and vaccine uptake. In our transition modeling, we see some evidence that Facebook, Twitter, and TikTok users who are pro are less likely to become hesitant or resistant. Facebook and Instagram users who are hesitant are more likely to become pro. Over the 3 survey waves, we find a positive association between Instagram and Twitter and being more likely to uptake the vaccine.

Our results on trust in information sources provide some more interesting details. As expected, we find a strong positive association between trust in government for vaccine information and being more provaccination, shown in our main PPO results in Table 4. However, we provide some additional evidence that some social media platforms may have a more positive effect on vaccine uptake preferences for those who do not trust the government. Our Table 5 results show Instagram, Twitter, and TikTok use is more positively associated with being more provaccination for those who do not trust the government, compared with those who trust the government. This finding points to a potentially positive role for some social media platforms. Potentially good information from trusted, non-government sources could reach those who lack trust in the government but are still open to being convinced on the merits of vaccination.

These findings provide a marginally positive picture for social media and vaccine uptake. However, given the concerns from the wider literature outlined in our introduction, we urge caution in how our results are interpreted. While social media could help increase vaccine uptake, our data do not strongly refute the potential for social media to also decrease vaccine uptake. Social media still has just as significant potential to spread bad information about vaccination to susceptible individuals. Indeed, the spread of misinformation via social media and its impact on vaccine hesitancy has been a key concern in the literature [22].

There are several reasons why we may not have found a negative association between social media use and vaccine preferences. First, a limitation of our study is the dataset itself. The social media question is only in the third survey wave, and asks about social media use over the previous 6 months. It would have been preferable to include social media use in each survey wave and ask about social media use over a shorter timeframe. Future research would also ideally cover other social media platforms that may spread misinformation, such as Telegram and YouTube. However, our mixed results by platform align with previous work that shows different social media platforms have varying effects on the spread of vaccine misinformation [29]. Despite these limitations, we argue that our novel analysis of a stated choice survey and the panel nature of the dataset still demonstrate a useful contribution.

Second, we undertake a web-based survey, with potential for sample selection bias. It seems likely that individuals with conspiracy beliefs will be less likely to undertake a survey from University researchers. Hence, we may have missed those at the most extreme end of resistance. As such, a survey may not be the best approach to understand the extremely resistant. Data pulled directly from the use of social media platforms may help in this regard [19]. Of course, analyzing such data can give a better idea of social media users, but it does not include a control of non-social media users, and may not be as clear in providing information about individual vaccine preferences.

Third, in the context of high government trust at the time in New Zealand, we find low levels of vaccine resistance of 4 to 7 percent, which is relatively low by international comparison [7]. This low proportion makes it impossible to identify the reasons behind the increasing levels of resistance we observed over time, without a much larger sample size. Thus, we acknowledge that other contexts are likely to have much higher potential for misinformation on social media, having a greater impact on levels of hesitancy or resistance. For instance, previous work in the United States using panel data found that social media was associated with higher levels of vaccine hesitancy during the COVID-19 pandemic [28]. Furthermore, we do observe polarization, with increasing levels of individuals in both the resistant and pro categories over time.

We note that a limitation of our data is that it cannot be interpreted as causal, hence, we frame our findings as associations between social media use and vaccine preferences. We collected social media use for individuals in survey wave 3, over the last 6 months. This period coincides approximately with the length of time between the first and third survey waves. However, this is second-best panel data; first-best would include recent social media use in each wave, meaning we could track longitudinally how changes in social media use change vaccine preferences. This would allow us to be closer to finding causal relationships, though we are not sure how much social media use changes over time, and therefore, if such an approach would allow us enough variation. There may still be potential endogeneity issues with such an approach. We also point out that the transition modelling gets us closer to a causal interpretation, as opposed to cross-sectional associations, as we see whether changes in vaccine preferences are associated with social media use between observations.

Other future research could use a similar stated preference panel data method to track the evolution of vaccine preferences. However, it would be helpful if it included more detailed questions on social media use and other sources of vaccine

XSL•FO
RenderX

information. Our study highlights the need to collect such vaccine preference data at the crucial point where new vaccines are developed and rolled out, so that we can study how preferences form. Thus, opportunities should be explored to collect such data on new COVID vaccines and other new vaccines in development.

While our study was overall positive in terms of social media use and vaccine uptake, we contribute to a literature with a mixed picture, as outlined in the introduction. The concerning potential for polarization to continue to increase is still ever present. The downsides are large, including both worsening public health as well as increasingly extreme political conflict based on disagreement over basic facts. Whether naive or bad actors are spreading misinformation, it is a pressing issue to both better understand the problem and potential solutions.

Acknowledgments

We would like to thank John Gibson for his very helpful and insightful guidance at an early stage of this research project. We would like to thank the participants of the 2022 New Zealand Association of Economists (NZAE) Annual Conference for their thoughtful and useful suggestions. We would also like to thank the wider authorship of Hess et al [7] for their input into the development of the survey. We acknowledge the Waikato Management School for providing funding for this project. SH acknowledges the financial support by the European Research Council through the advanced grant 101020940-SYNERGY.

Abstract

Background: The analysis of social networks should be considered by institutions and governments alongside surveys and other conventional methods for assessing public attitudes toward vaccines. X (formerly known as Twitter) has emerged as a significant source for studying vaccine hesitancy.

Objective: The aim of the study is to examine the main arguments and narratives in favor and against vaccination expressed in Spanish- and Catalan-language posts, comments, and opinions on the social media platform X.

Methods: Spanish and Catalan posts were collected from X using NodeXL Pro between March and December 2021, resulting in 479,734 posts. For qualitative analysis, a random subsample of 384 tweets was selected using Cochran's formula (95% confidence and ±5% margin of error). A bespoke code frame was developed in collaboration with medical and social media experts, and posts were translated into English. Intercoder reliability, assessed on 20% of the sample, yielded 93.4% agreement and a Cohen κ of 0.92.

Results: A total of 479,734 posts were retrieved from 29,706 users. After an inductive review of the data, six themes were identified, which formed the basis of our code frame: (theme 1) vaccine acquisition and distribution, (theme 2) vaccine skepticism and criticism, (theme 3) provaccination stance, (theme 4) global COVID-19 situation, (theme 5) vaccine politics and international relations, and (theme 6) miscellaneous news and posts. Vaccine skepticism and criticism was the most frequent theme (93/384, 24.2%), whereas vaccine politics and international relations was the least (25/384, 6.5%). We observed that while some posts supported vaccination, others expressed concerns about vaccine safety and efficacy, promoted conspiracy theories, disseminated misinformation, or opposed scientific consensus. Challenges related to vaccine acquisition and distribution within specific countries

XSL•FO
RenderX

were also identified, along with political and economic factors, such as the politicization of vaccines, which hindered equitable distribution between vaccine-producing and vaccine-needing countries. Additionally, the pandemic's social impact fostered community support initiatives and solidarity.

Conclusions: Our findings can inform measures to promote vaccine acceptance and reinforce trust in health care systems, professionals, and scientific perspectives, thereby improving vaccination coverage. These insights may serve as a foundation for developing sociopolitical strategies to enhance vaccination management and address future pandemics or new vaccination campaigns.

(JMIR Infodemiology 2025;5:e67942) doi:10.2196/67942

KEYWORDS

antivaccination movement; vaccine refusal; social media; misinformation; vaccination practices; vaccine hesitancy; immunization

Introduction

The internet and social media (SM) have transformed how the public accesses health information [1-4]. X (formerly known as Twitter) has become a significant source for studying vaccine hesitancy, as SM platforms are considered effective tools for communication between individuals and organizations. However, they have also been used to disseminate false information and conspiracy theories about vaccines [5-9].

SM allow individuals to rapidly create and share content on a global scale without editorial oversight. Users can self-select content streams, contributing to ideological isolation. Consequently, antivaccination messages on these platforms are of significant public health concern, as they can lead to vaccine hesitancy [5].

Exposure to antivaccine content on SM has been linked to delays in and refusal of vaccination [10,11]. A decline in vaccination coverage threatens herd immunity and could lead to outbreaks of diseases, such as the measles outbreak in Europe in 2023-2024. Current literature has not yet fully elucidated how the antivaccine movement continues to engage and persuade the public to refuse immunization despite efforts by provaccine advocates to counteract these messages [10].

The spread of antivaccine misinformation is a significant public health challenge influenced by multiple interconnected factors. SM algorithms prioritize engagement-driven content, often amplifying misleading narratives and creating echo chambers that reinforce vaccine skepticism [5,12,13]. On social media, antivaccine advocates address a broader range of topics than provaccine advocates, and previous research has shown that such thematic diversity is associated with higher levels of user engagement. [14-16]. Antivaccine advocates also demonstrate more persuasive and influential narratives than those advocating for vaccines [10]. The rapid dissemination of misinformation, frequently originating from nonexpert sources or commercial entities, further undermines public confidence in vaccines [13,17]. Interaction tends to be higher with antivaccine content than with provaccine content on platforms such as Instagram and Facebook [12,18]. Although antivaccine groups are a minority, they have the potential to be more influential than provaccine groups. Furthermore, undecided groups are not passive; they are the most active participants in the discussion. This dynamic favors interaction between the undecided and antivaccine groups [15].

Conspiracy theories regarding vaccine development and governmental motives exacerbate distrust in public health initiatives [19,20], while ideological polarization limits exposure to scientifically accurate information [13,20]. Previous qualitative studies have reported that provaccine websites focus on accurately conveying evidence-based scientific research on vaccines and government-endorsed vaccination practices, whereas vaccine-skeptic websites aim to build communities of individuals who perceive themselves as affected by vaccines and related practices while questioning the information presented in scientific literature and government documents. Indeed, antivaccine advocates disproportionately emphasize safety concerns while downplaying the preventive benefits of vaccines [4,10].

Recent studies have explored vaccine hesitancy narratives in English-speaking contexts [20-22]; however, less is known about how these discussions unfold in other linguistic and cultural settings, such as Spanish- and Catalan-speaking communities. The objective of this study was to examine the main arguments and narratives in favor and against vaccination expressed in Spanish- and Catalan-language posts, comments, and opinions on the SM platform X. A qualitative approach was essential to enable an in-depth analysis of the discourses, meanings, and sentiments conveyed in these conversations, which cannot be fully captured through quantitative methods alone.

Methods

Data Retrieval

Posts were gathered from "X" drawing upon NodeXL Pro. The search string in order to retrieve posts was as follows: "vacunacion OR vacunacio OR vacunas OR vacunes OR antivacunas OR antivacunes OR antivacinacion OR antivacunacio." These keywords were selected after experimenting with Twitter using the advanced search feature. It was found that, as a collection of keywords, these captured an excellent sample of posts. The way NodeXL Pro captures data means that any of these keywords in their hashtag form, for example, #vacunacion would also have been captured. In addition to this, any replies or mentions to posts with these keywords would also have been captured.

NodeXL Pro previously had access to the Academic Track application programming interface (API) provided by Twitter at the time, which allowed users to retrieve all posts for a topic.

XSL•FO
RenderX

However, after the closure of the Academic Track API, affordable academic means to access data became problematic. However, through NodeXL Pro's new importer, it is possible to capture a random sample of posts across the various months. It is not possible to quantify the sample in terms of the percentage of the entire conversation, and this is further discussed within our limitations.

Our keywords reflect a set of keywords in both Spanish as well as Catalan (spoken in Catalonia, the Balearic Islands, and the Valencian Community). Data were retrieved using NodeXL Pro, which collects a random sample of posts from X based on the specified search terms. However, the underlying parameters of the sampling procedure are not known due to these data not being published and too costly to obtain for most academic research teams. As such, while the dataset reflects activity around the selected queries, it is not possible to determine the precise representativeness of the sample or to know what larger universe of posts it was drawn from. This differs from tools such as the (now discontinued) Twitter Academic API, which provided access to the full stream of eligible posts. These points are further discussed in our limitations.

Duplicate posts were removed from the dataset. However, no bot detection analysis was applied; therefore, automated accounts (bots) may still be present in the sample, and this is further discussed in our limitations.

A total of 479,734 posts were captured (excluding reposts), and the data were retrieved from X between March 2021 and December 2021. We specifically selected 2021 because this corresponds to the second phase of the COVID-19 vaccine rollout where governments began to step up the rollout periods. Table 1 provides an overview of our sample broken down per month.

Table 1. Overview of data (tweet volumes and total number of X users).

Month (2021)	Total posts, n	Total X users, n
March	54,837	40,093
April	53,793	39,426
May	53,613	39,114
June	54,499	38,590
July	54,074	40,170
August	54,002	39,303
September	47,141	33,402
October	35,071	25,545
November	35,417	27,944
December	37,287	29,706
Total	479,734	__[a]

[a]Not applicable.

Qualitative Data Analysis

The data were randomized using a formula in Microsoft Excel, and the team met, reviewed, and discussed the data. A code frame was developed in discussion with medical experts from Spain and expert SM analysts. Although many existing code frames could be used and adapted, due to the highly contextualized Spanish and Catalan languages within the posts, a specific code frame was developed within this context. A sample size was calculated to ensure that a systematic representative sample was analyzed. To determine a sample size sufficient for estimating proportions with a 95% confidence level and a ±5% margin of error, we used Cochran's formula [23], which yields a sample size of 384 (rounded up). Thus, a random sample of 384 tweets was drawn to provide a representative estimate within ±5% error at 95% confidence. Spanish and Catalan language posts were carefully translated into English to provide example posts for the qualitative analysis. This translation was overseen by a Spanish-speaking expert assisted by translation software such as Google Translate. To assess the consistency of the coding process, a second coder independently coded a sample of 20% (n=77). The intercoder reliability analysis showed a percentage agreement of 93.4%. To account for agreement occurring by chance, Cohen κ was also calculated. The κ coefficient was 0.92, which is considered an indicator of good reliability [24]. Our team further analyzed each of the categories from our code book drawing upon thematic analysis. This enabled the identification of themes, and sub-themes and further interpretative depth

Ethical Considerations

This study was approved by the ethics and clinical research committee of Fundació Institut Universitari per a la Recerca a l'Atenció Primària de Salut Jordi Gol I Gurina (code 20/221-P). The study was conducted in accordance with the principles of the Declaration of Helsinki. Data were collected using tools that accessed publicly available accounts and domains on the internet. The content obtained through these tools was publicly accessible. Our study drew upon tools such as Grammarly and ChatGPT-4 to assist in improving our language and clarity of expression. However, these tools were not used to generate ideas on their own. Our team maintains full responsbility for the work.

Results

Descriptive Overview

Figure 1 provides a visual overview of the 6 key themes that emerged from the data. Table 2 provides an overview of the descriptive statistics and frequencies associated with each of the themes. The table shows the distribution of 384 tweets across 6 themes related to vaccines and COVID-19. The largest share falls under vaccine skepticism and criticism (93/384, 24.2%), while the smallest share is vaccine politics and international relations (25/384, 6.5%).

Figure 1. Visual overview of themes to emerge.

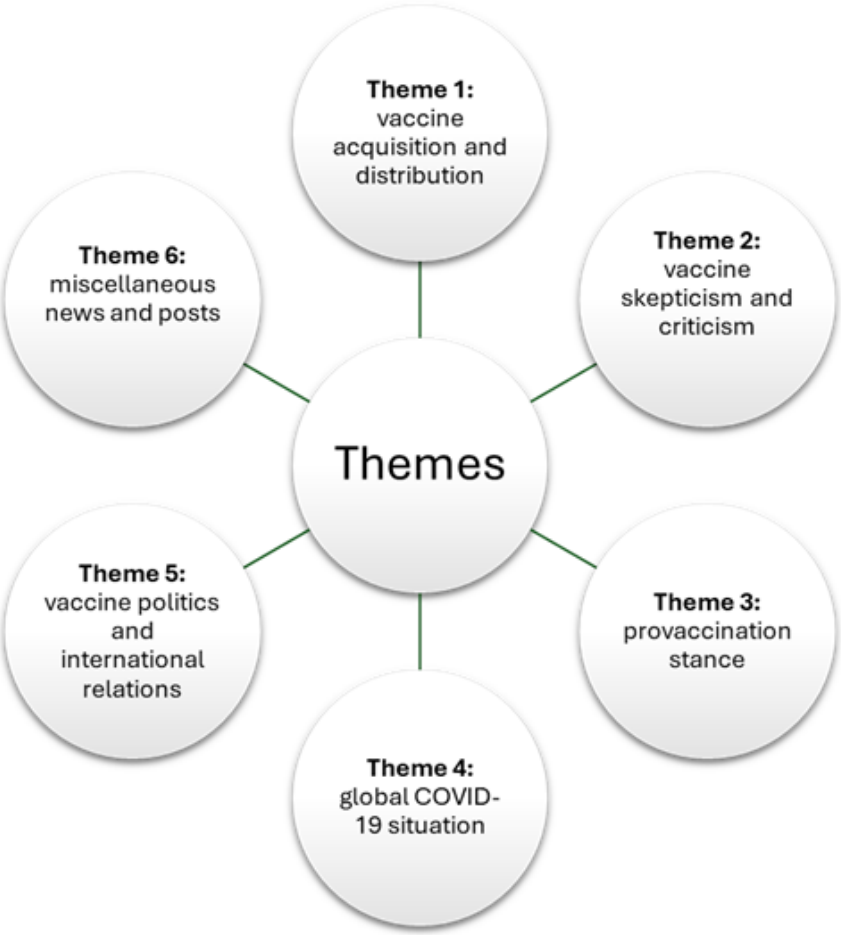

Table 2. Descriptive overview of theme frequency.

Theme	Values, n (%)
Theme 1: vaccine acquisition and distribution	57 (14.8)
Theme 2: vaccine skepticism and criticism	93 (24.2)
Theme 3: provaccination stance	72 (18.7)
Theme 4: global COVID-19 situation	68 (17.7)
Theme 5: vaccine politics and international relations	25 (6.5)
Theme 6: miscellaneous news and posts	68 (17.9)

Theme 1: Vaccine Acquisition and Distribution

This theme revolved around the logistics and strategies for obtaining and distributing vaccines. Concerns about availability, prioritization, and fairness in vaccine distribution were vital to user discussions.

An example of a post included: “Arrival of the Sinovac vaccines this morning at the CDMX airport. Over 10 million vaccines already in Mexico. Good day!”

The post updated users about the arrival of the Sinovac vaccines in Mexico and appeared celebratory. It highlighted successful vaccine procurement and noted the steady progress in Mexico’s vaccination efforts. The use of “Good day!” communicated a sense of relief or achievement, highlighting the importance of vaccine shipments for public morale and the ongoing battle against COVID-19.

Another illustrative post within this theme included: “Is there something we don’t know about? Aren’t the vaccines arriving

XSL•FO
RenderX

in Burgos? Isn't there staff to administer them? We need an explanation!"

This post reflected concern and uncertainty around the vaccine distribution process in Burgos. The questioning tone, "Is there something we don't know about?" indicated a perceived lack of transparency or communication from authorities or agencies involved in vaccine management. The post noted the need for clear communication to the public regarding vaccine acquisition, distribution, and administration status.

Other users also questioned the distribution of vaccines in Spain and made claims about missing vaccines. For instance, one user noted:

> *In the Community of Murcia, more than 600 vaccines disappeared, and there were hundreds of claims of corruption that will not be investigated for now, contrary to those of the City Council. The best way for the PP to continue plundering Spain with impunity is for C's to disappear.*

The author claimed that over 600 vaccines had gone missing in this region, accompanied by numerous allegations of corruption. The statement also carried a strong political accusation, specifically against the People's Party, accusing them of exploiting the situation for their benefit. The author believed that the People's Party was engaging in corrupt or self-serving practices at the expense of the public.

Another user made a broader point about charging for vaccines in general:

> *How many measles or polio vaccines were charged for during the "neoliberal" period? Even giving space to such stupid words is an offense to people's intelligence. @UserHandle is desperate and has to say whatever it takes to stay afloat.*

This post appeared to criticize charging for essential vaccines like measles or polio during a previous political period, which the user labeled as "neoliberal." The mention of these specific vaccines highlighted a broader conversation about vaccine accessibility and affordability, a point of contention regardless of the pandemic. The user's frustration indicated criticism of past and present public health and vaccine distribution approaches.

Theme 2: Vaccine Skepticism and Criticism

Some posts reflected doubts or criticisms about the efficacy, safety, or necessity of vaccines. This theme highlighted the challenges in combating vaccine misinformation and skepticism. Within this theme, 5 subthemes emerged.

One subtheme focused on distrust toward the pharmaceutical industry. Several posts noted concerns over the profit motives of vaccine-producing companies, reinforcing broader skepticism toward the industry. These views were also backed by certain users who were suspicious regarding the rapid development and approval of COVID-19 vaccines.

Another subtheme involved doubts about vaccine efficacy and potential side effects. Some users questioned the level of protection provided, while others voiced concerns about long-term effects, arguing that these risks were either unknown or not fully disclosed.

A third subtheme was the belief in the superiority of natural immunity over vaccine-induced immunity. Many users skeptical of vaccines called for and advocated natural immunity. Moreover, these users expressed skepticism toward external medical interventions, favoring holistic or natural treatments.

Political and ideological perspectives represented another subtheme. Some users perceived vaccination campaigns as mechanisms of governmental control. Discussions branched out, associating vaccination mandates or passports with infringements on personal freedoms.

Finally, misinformation played a crucial role, forming the fifth subtheme. Some posts contained references to conspiracy theories or unfounded claims, such as unverified side effects or misleading arguments in favor of natural immunity. These posts often linked to dubious sources of information. Table 3 provides an overview of post extracts associated with the above subthemes.

XSL•FO
RenderX

Table 3. Post extracts for theme 2: vaccine skepticism and criticism.

Subtheme	Post extracts
Distrust in pharmaceutical industry	• "Why #vaccine safety and efficacy aren't known: FDA decided not to require the pharmaceutical companies to track this rigorously once emergency use authorisation had been granted." • "100% agree ... !!! Technically all those, and what, vaccines are nothing more than experimental potions that can poison and lead to death ... !!! ." • "I don't believe in the 'virus,' they have hacked the flu, always ... These are not 'vaccines,' they are something else ... I'll leave it at that ..." • "Thanks for the clarification, you are telling me that the population is being vaccinated with experimental vaccines, that they are conducting a clinical trial. And if I remember correctly what was being said was that there were deaths from COVID due to the experimental liquid. ."
Questioning efficacy and side effects	• "These are vaccines that have not been around for long ... We have no idea if they will have any long-term side effects." • "I hope they don't cause neurological damage, as it has been proven that vaccines can cause autism among other neurological diseases." • "Deaths increased starting from March with the vaccines." • "CDS cleanses the body of heavy metals that come in vaccines. You can contact @UserHandle they use it with immense success."
Natural immunity advocacy	• "My body, my choice. Natural immunity for me. I don't need the vaccine. Leave our children out of this world-wide experiment." • "Natural immunity is broad, protective, and durable. Unlike vaccine-induced immunity." • "Vaccinated individuals have 27 times higher risk of symptomatic COVID infection compared to those with natural immunity."
Political and ideological angles	• "They plan to provoke as many pandemics as necessary to bring humanity to its knees, until everyone submits to their global control, gives in to genocidal vaccines, to alter DNA, to diminish the world's population, to sterilise." • "Public order has nothing to do with your uselessness and corruption with the vaccination plan. You won't achieve anything with blackmail, you bastards." • "Vaccine passports are not 'our route back to normality.' They are our route to permanent abnormality, a nightmarish checkpoint 'Where are your papers?' society of medical apartheid, discrimination and digital slavery. #StopVaccinePassports #NoNewNormal #DefendFreedom." • "What they call vaccination did not come because of the so-called covid, but covid came to justify what they call vaccination. I just read something similar, and I'm afraid it's true. Disobedience is the only vaccine. #MiVidaMiOxigeno #DictatureSanitaire #SpainDictatorship."
Influence of misinformation	• "A high-elite athlete who is permanently monitored has never had anything detected and now suddenly has to quit football? An investigation would have to be done. I also suspect that it is yet another case of these vaccines." • "I don't believe in the 'virus,' they have hacked the flu from all our lives ... These are not 'vaccines,' they are something else ... I'll leave it at that ... But I'm not so 'picky,' I respect freedom and debate. Thank you and welcome to anyone who fights against this tyranny ... From the heart ." • "This is worrying. This information has to be known, and then everyone will learn how to act, but when you make things known, you disappear. The body of the doctor who linked vaccines to autism was found floating in the river." • "Shocking video!! The Puppet doctor of the laboratories, who for years was used to testify that vaccines 'do not produce autism' ... now he repents and claims the opposite!!!"

Theme 3: Provaccination Stance

This theme captured posts expressing a positive view toward vaccination, emphasizing its importance in combating the pandemic and urging others to vaccinate. Within this theme, 5 subthemes emerged.

One key aspect was scientific trustworthiness, as users who supported vaccinations emphasized the rigorous testing and validation processes that vaccines underwent. Moreover, users highlighted the endorsements from reputable scientific bodies.

Another subtheme focused on societal responsibility, with an extensive range of users expressing advocacy for vaccination as a communal duty to achieve herd immunity. For these individuals, the interconnectedness of individual actions and broader societal health was essential for preventing the spread of disease.

A third subtheme involved historical successes, as users drew parallels to past vaccination campaigns and their success in eradicating diseases across history. By using historical data and facts, they aimed to validate the effectiveness of vaccines.

Emotional appeals also played a significant role in these discussions. Many users shared personal stories of individuals who were saved by vaccines or those who experienced vaccine-preventable diseases. There was also a range of testimonies shared by frontline workers witnessing the impacts of COVID-19 first-hand.

Finally, debunking myths emerged as a crucial aspect of this theme. In contrast to subtheme 5 from theme 2, which focused

XSL•FO
RenderX

on vaccine skepticism and criticism, users in this theme aimed to directly address and dispel common misconceptions about vaccines. Users here sought to use facts and evidence-based research to counter misinformation. Table 4 provides an overview of post extracts associated with the above subthemes.

Table 4. Post extracts of theme 3: provaccination stance.

Subtheme	Post extracts
Scientific trustworthiness	• "The risk of autism and vaccines is more than disproved, on June 23 a review of 338 studies on the safety of vaccines was published concluding that there is no risk for autism." • "Let's not forget the damage caused by a false association of vaccination with autism risk. When you have something with an acceptable level of scientific evidence, feel free to share it." • "Guess what did make a difference in controlling the pandemic: vaccines. #FuckIvermectinaParaCOVID #AlwaysTrustScience." • "Vaccines save lives. It's a simple fact. This isn't a debate; it's science. #GetVaccinated #StaySafe."
Societal responsibility	• "The more of us that get vaccinated, the quicker we can return to normal. It's not just about protecting yourself but also those around you." • "You still know people in your close circle who are not vaccinated. If you were able to bring a non-regular voter, also try to take advantage of the situation and explain to them the need for vaccines. Do not accept the normalisation of such an antisocial action!" • "Let's help in this campaign, for each RT or reply to the cited tweet, UNICEF partners will unlock $1 for UNICEF vaccine programs. Always united #ARMY #VaccinesWork #BTSArmyColombia @UserHandle."
Historical successes	• "For me, the important thing is that vaccines hold up very well for serious diseases, and I'm pretty sure that's not going to change now." • "The mRNA vaccine story illuminates the way that many scientific discoveries become life-changing innovations: with decades of dead ends, rejections and battles over potential profits, but also curiosity and dogged persistence against scepticism and doubt." • "In the U.S., there have been more than 30 years without people affected by polio thanks to the vaccine."
Emotional appeals	• "The more of us that get vaccinated, the quicker we can return to normal. It's not just about protecting yourself but also those around you." • "To have the country we want, we have to get vaccinated as we should. Go to your nearest vaccination site and get your first or second dose of a COVID-19 vaccine. #VacúnateYa #JornadaVacúnateYa #VacúnateRD." • "The comptroller @correa_catalino calls on the entire population to get vaccinated against covid-19. The faster you get vaccinated, the faster the country reactivates! #VacúnateRD." • "Received my second dose today! Feeling grateful for the scientists, healthcare workers, and everyone who made this possible. #Vaccinated."
Debunking myths	• "If you've not followed the story of how some Americans have turned to a drug called Ivermectin to treat or prevent COVID despite no public evidence it does this, a tweet can't do it justice. Trust me, it's worth 7 minutes." • "This delta variant is every infectious disease specialist's worst nightmare ... There was a myth ... that children were somehow immune ... It has become very clear that children are heavily impacted." • "Catching Covid-19 after being vaccinated isn't a myth. It happened to me: towards herd immunity: Social distancing + Diagnostic tests + vaccination."

Theme 4: Global COVID-19 Situation

Posts under this theme provided a snapshot of the current state of the pandemic worldwide, including discussions of variants, infection rates, and the overall impact of the virus. For example, one user noted: "The pandemic continues to surge in several countries. When will this end? My heart goes out to everyone suffering. #COVID19 #StaySafe."

This post echoed a sentiment of global concern and empathy, highlighting the persistent nature of the pandemic across various countries. The longing to end the crisis and express compassion for those affected spoke to the shared global experience and the challenges many faced.

In another post, a user noted: "Seeing the statistics every day is heartbreaking. Numbers are not just numbers; they represent people.  #COVID19 #PandemicLife."

This post sought to humanize the numbers, reminding readers of the personal tragedies that comprised the aggregated data and emphasized the crisis's depth.

Other users reflected on the past; for instance, a user noted: "A year ago, we thought it would be over in a few months. The unpredictability of this virus is something else. #COVID19."

The post captured the evolving nature of the pandemic and the challenges in predicting its trajectory. The reflection on past expectations versus the current reality underlined the persistent and unpredictable nature of the virus.

Theme 5: Vaccine Politics and International Relations

Posts within this theme delved into the political dimensions of vaccine distribution, acquisition, and diplomacy. The interactions between nations, the roles of international entities, and geopolitical factors influencing vaccine-related decisions were central to this theme.

XSL•FO
RenderX

For example, one user posted: "The power dynamics in the global health community is evident. Wealthy nations holding the majority of vaccine supplies is a blatant display of neocolonialism. #VaccineEquity."

This post brought to the forefront the perceived imbalances in global health distribution, particularly around vaccines. Labeling it as "neocolonialism" signified deep-rooted historical connotations where wealth and power were concentrated among a few nations at the expense of others.

Another user posted: "The vaccine diplomacy being played out between superpowers is worrisome. Are we pawns in their global game? #VaccineDiplomacy."

This post emphasized concerns over the geopolitical strategies major powers undertook, using vaccines as a tool. The phrase "pawns in their global game" suggested that the well-being of citizens might have been secondary to broader political aims.

Another user also noted: "Countries leveraging vaccines for political favors sets a dangerous precedent. Public health should transcend politics. #VaccinePolitics."

The post highlighted the potential risks when vaccines became intertwined with political agendas. The call for public health to "transcend politics" was a plea for prioritizing humanity and well-being over political maneuvers.

In the broader context of vaccine policies, a user also noted: "I was in a public school 40 years ago, and even then, a vaccination card was required for enrolment, and it was perfectly normal."

This post reflected on past public health practices in schools, where the user shared their experiences with vaccination cards as a regular part of enrollment procedures. It suggested a historical acceptance and understanding of the importance of vaccinations for public health. The post indirectly supported the idea that vaccinations have been an integral and uncontroversial part of societal norms, promoting the general well-being and safety of communities long before the advent of COVID-19.

Theme 6: Miscellaneous News and Posts

This theme covered general updates, news, and other miscellaneous information about vaccines and the pandemic. For instance, a user noted: "It's heartwarming to see communities come together, setting up local vaccine drives and educating each other. Unity in times of crisis. #CommunityResponse."

This post highlighted the positive aspects of collective behavior, showcasing the power of community resilience and cooperation during trying times. The emphasis on localized initiatives and educational programs highlighted the presence of grassroots movements, which were indicative of community-driven efforts to foster systemic change from the bottom up, rather than relying on top-down institutional mandates.

Another user also noted: "In a world where everyone has an opinion, it's tough to sift through the noise. Wish there was more emphasis on science in public discourse. #DrowningInOpinions."

This post examined the challenges of information overload in the digital age. The desire for a stronger emphasis on science indicated a concern about misinformation or the dilution of factual discourse in the public realm.

Another user also shared the following post: "Just read a story about a small town turning their community center into a space for COVID survivors to share stories and heal. It's not all about stats and data; it's about people and their journeys. #HumanSideOfPandemic."

This post brought attention to the human aspects of the pandemic beyond just numbers and data. It highlighted the importance of emotional healing and community support in navigating the crisis. The resilience and adaptability of communities were evident in their self-organized responses to crises. Local initiatives, whether vaccine drives or support groups, played a crucial role in bolstering societal well-being.

Another example of a broader post included the following: "Vaccines are arriving, restrictions are in place, so the system doesn't collapse. They sold you the idea that the goal is to destroy the national government at all costs, even if it means risking your own life. It seems to me that you are being used."

This post discussed the broader dynamics around vaccination and public health measures and highlighted the wide type of conversations within this theme. The user seemed to criticize a narrative that accused the government of implementing vaccination and restriction policies for ulterior motives, suggesting instead that these measures were meant to protect public health and prevent the health care system overload. While they involved vaccines, these discussions often revealed deeper societal and political tensions and were illustrative of the complex environment in which health policy was debated and implemented.

Discussion

We conducted a qualitative content analysis of comments and opinions from posts in Catalan and Spanish regarding vaccination and antivaccination in X, identifying 6 predominant themes:

Theme 1: Vaccine Acquisition and Distribution

The spectrum of experiences highlighted in the posts illustrated the challenges different nations and regions face in their vaccination campaigns. While some celebrated milestones, others encountered uncertainties and sought answers, emphasizing the uneven landscape of global vaccine distribution. Transparent and effective communication emerges as a fundamental element in vaccination campaigns. Ambiguity may foster confusion, mistrust, or even the spread of misinformation [25]. Ensuring that the public remains informed and confident requires clear communication channels between governing bodies and the population [26]. The Strategic Advisory Group of Experts (SAGE) Working Group on Vaccine Hesitancy categorized vaccine hesitancy using a matrix of contextual, individual or social, and vaccine- and vaccination-specific issues [27]. This theme of vaccine acquisition and distribution is classified as a contextual determinant that influences vaccine

XSL•FO
RenderX

acceptance or rejection, as defined by the SAGE Working Group [28,29]. Additionally, according to the World Health Organization's (WHO's) "3Cs" (confidence, complacency, and convenience) model, convenience in vaccines and in the health care system constitutes 1 of the 3 main determinants of vaccine hesitancy [29]. It has been demonstrated that proper vaccine distribution prevents significant morbidity and mortality [30], as evidenced by the fact that the implementation of the WHO's Expanded Programme on Immunization has averted 154 million deaths over the past 50 years [31].

Theme 2: Vaccine Skepticism and Criticism

Some posts reflected doubts or criticisms regarding vaccines' efficacy, safety, or necessity. These posts focused on skepticism toward the COVID-19 vaccine, which was more prevalent at the time, as well as skepticism about vaccines outside the context of COVID-19. In these posts, the efficacy of vaccines was questioned, and secondary effects were attributed to the vaccines or their components, alongside conspiracy theories. The skepticism highlighted in these posts extended beyond the vaccines themselves, challenging the entire COVID-19 narrative, from the existence of the virus to global response strategies. Such deep-rooted skepticism presents a significant barrier to the universal acceptance of health guidelines and interventions. The emotive nature of these views suggests that simply countering them with facts may not be sufficient. Addressing these perspectives requires a comprehensive strategy that disseminates accurate information and rebuilds trust. The challenge lies in effectively communicating health information to a divided audience. These findings are consistent with previous studies showing that vaccine-skeptic websites emphasize safety concerns and question the information presented in scientific literature and government documents [4,10]. Confidence in vaccines is 1 of the 3 main determinants of vaccine hesitancy described by the WHO's "3Cs" model [29]. Vaccine hesitancy is complex and context-specific, varying across time, place, and vaccines. Vaccine hesitancy may be influenced by a combination of sociodemographic and socioeconomic factors [32-34], psychological perceptions [33,35,36], concerns about vaccine safety and efficacy [33,35,37,38], trust and confidence [32,35,37,39], information and communication [34,35,40], as well as cultural, social, and political influences [22,34,40]. A prepandemic publication analyzing the psychological factors that might motivate people in 25 countries to refuse vaccination showed that the best predictors of refusal were the following: high levels of conspiracy beliefs, low tolerance of perceived infringement of personal freedom, aversion to needles or blood, and religious beliefs [41]. A review during pandemics highlighted the complexity of factors related to acceptance or refusal of vaccines including demographic factors (ethnicity, age, sex, pregnancy, education, and employment), accessibility and cost of vaccines, personal responsibility and risk perceptions, trust in health care authorities and vaccines, safety and efficacy of new vaccines, and lack of information or misinformation [34]. These factors do not act in isolation but are interconnected with a range of contextual, individual, and vaccine-specific influences, shaping vaccination decisions, as highlighted in the WHO 3Cs model [27,29].

Some posts in our study linked vaccines or their components to neurological damage and autism, referencing the 1998 study by Wakefield et al [42], which falsely claimed an association between the measles-mumps-rubella vaccine and autism. The *Lancet* later published a retraction of the paper due to the false claims it contained [43]. Despite this, the paper of Wakefield et al [42] continues to accumulate a significant number of citations [44] and was linked to a sharp decline in childhood measles-mumps-rubella vaccination rates, leading to subsequent measles outbreaks [45].

Theme 3: Provaccination Stance

These posts captured the essence of a movement that was not only rooted in scientific belief but also emphasized community welfare and solidarity. The emphasis was not solely on personal health but on the collective well-being of society. The concept of collective responsibility is 1 of 5 factors that affect people's perception of vaccines, along with confidence (trust in vaccine efficacy and safety), complacency (perception of the risk of the disease), calculation (weighing the risks and benefits of vaccines), and constraint (accessibility of information about the vaccine) [46]. These are part of the 5Cs model [46], which extends from the 3Cs model introduced by the WHO SAGE Working Group [29].

Although the provaccination messages in our study were not predominant, they reflected trust in the scientific community and its advancements, particularly during the pandemic. This indicated a broader sentiment that valued empirical evidence and the progress of modern medicine. In an era where misinformation can spread rapidly, these posts acted as counternarratives that upheld scientific principles. However, the influence of provaccine content is often limited by its emotional or narrative appeal [16,47], the network dynamics of antivaccine messages [12,15,48], the spread of misinformation [49], and the challenges of effectively communicating scientific consensus [50,51]. Provaccine messages that rely solely on scientific knowledge tend to be less engaging [16,47], whereas antivaccine messages often use emotional narratives such as government conspiracies or alleged vaccine harm, which resonate more strongly and generate higher engagement [4,10,52]. SM platforms often create echo chambers, where users are primarily exposed to information that aligns with their existing beliefs [12]. Antivaccine clusters are more interconnected and engage more frequently, reinforcing their views, while provaccine clusters are more fragmented and peripheral [48]. A previous study published in 2020, which analyzed global Facebook users, indicated that although antivaccine groups were a minority, they may have been more influential than provaccine groups [15]. Antivaccine content often simplifies complex issues, making them more accessible and easier to understand, which can lead to its wider dissemination and acceptance [49]. Scientific consensus can reduce concerns about vaccines, but it is not always effective in changing the attitudes or intentions of those who distrust scientists [50,51]. Provaccine messages must convey confidence and reassurance, both informationally and emotionally, to effectively counter antivaccine narratives [10,52].

Theme 4: Global COVID-19 Situation

The global reach of the pandemic meant that people across different countries and cultures were sharing remarkably similar experiences and challenges. This collective ordeal has the potential to foster international solidarity, even as it also reveals disparities in resources and responses. The daily barrage of statistics and news not only informed but also profoundly affected many. The emotional impact of the continuous stream of information was especially evident. The posts highlighted the shared challenges, the emotional toll, and the evolving nature of the pandemic, emphasizing the need for global collaboration, mental well-being, and adaptability. The WHO published a scientific brief in 2022, highlighting the impact of the COVID-19 pandemic on the prevalence of mental health symptoms and mental disorders as well as the effectiveness of psychological interventions in preventing or reducing mental health problems and/or maintaining access to mental health services [53].

Theme 5: Vaccine Politics and International Relations

The posts in our study showed that during the COVID-19 vaccination process, it became evident that political and public health factors were interconnected with the economy. The disparities in vaccine distribution and access among nations were not just logistical but deeply political [54]. The advent of "vaccine diplomacy" demonstrated how crucial medical supplies could be leveraged for geopolitical influence [55,56]. Such practices could potentially jeopardize genuine public health efforts by introducing additional layers of strategic considerations. The politicization of vaccines could set precedents for future global health crises. The unequal distribution of vaccines during the pandemic was also evident in other published papers, which highlighted how manufacturing countries and those reliant on imports vied for diplomatic advantage. The former sought to achieve hegemony, while the latter aimed to secure vaccine supplies [55,57-60].

Theme 6: Miscellaneous News and Posts

Given the wide-reaching impact of the COVID-19 pandemic, it was unsurprising that it generated a broad range of discussions. This theme also captured the miscellaneous conversations, which, while not directly related to vaccines or governmental responses, shed light on the narratives that shaped public sentiment. Moreover, the wide range of personal stories and experiences that arose during such a global crisis underlined the importance of listening to and understanding these voices as we reflected on the pandemic. It served as a reminder that each post represented a person with their unique journey and their challenges. The resilience and adaptability of communities were evident in their self-organized responses to crises. Other publications also showed that community support initiatives were implemented during the pandemic to enhance connectivity, reduce isolation, and facilitate the sharing of critical information and resources [61,62]. Based on our study's findings, we believe that strengthening trust in the health care system and combating misinformation through community actions are key to reducing vaccine hesitancy.

Limitations and Future Research

A limitation of our study is that the qualitative content analysis of Spanish posts focused specifically on the X network in 2021, during the COVID-19 pandemic, and our results reflect opinions influenced by the pandemic. Nevertheless, our study reveals reasons for vaccine acceptance or hesitancy that had been previously described by the WHO before the pandemic, such as trust in the health care system and scientific attitudes, as well as the efficacy and safety of vaccines. These factors continue to be relevant in the current context. Another limitation of the study was the inherent recruitment bias associated with restricting participation to individuals with internet access. Several studies have analyzed public opinions or sentiments about vaccines on X using artificial intelligence. These publications suggest that institutions and governments should consider analyzing social networks with artificial intelligence alongside surveys and other conventional methods for assessing public attitudes toward vaccines [6,10,63-65]. Future research could aim to extend the time periods and examine discussions on X in relation to other SM platforms. Future research could also seek to combine qualitative and quantitative approaches in order to gain a statistical understanding of the topic. This could include user demographics as well as engagement metrics. Moreover, it is also important to note limitations ascertaining to the analysis of a single platform. This can introduce platform dynamics, such as echo chambers, and algorithmic bias, which will consequently impact the results and themes that emerge from a platform. There are also limitations in regards to the absence of non-Spanish or Catalan speakers as well as offline populations. In regard to language, due to limitations in geocoded data from Twitter, our data captured posts sent in Spanish or Catalan from around the world. Future research could seek to isolate and compare different regions. A further limitation of this study is that we did not implement bot detection methods. As a result, some automated accounts (bots) may remain in the dataset, which could have influenced the nature and frequency of certain themes. Future work could incorporate bot-detection approaches to strengthen the robustness of analyses. A further important limitation concerns the use of NodeXL Pro for data retrieval. NodeXL Pro provides a random sample of posts, but the sampling parameters are not available due to the cost and complexity of obtaining data. This means we cannot determine the exact population of posts from which our dataset was drawn. While this does not affect the qualitative thematic insights, it does limit the generalizability of descriptive statistics. Future research could build on our inductive findings by mapping them onto established frameworks such as the WHO's 3Cs model. This would allow the exploration of how context-specific themes identified in Spanish and Catalan discourse align with or diverge from broader patterns of vaccine hesitancy. Despite these limitations, our study provides valuable insights into Spanish and Catalan vaccine opinions, though caution is warranted when extrapolating the findings to the entire population.

Conclusions

Our study enabled the analysis of Spanish- and Catalan-language posts concerning opinions for and against vaccination, the social and political impact of the COVID-19 pandemic, and the

XSL•FO
RenderX

acquisition and distribution of vaccines. We observed that while some posts supported vaccination, others raised concerns about vaccine safety and efficacy, promoted conspiracy theories, spread misinformation, or opposed scientific consensus. Challenges related to vaccine acquisition and distribution within certain countries were also identified, while political and economic factors, such as the politicization of vaccines, hindered equitable distribution between vaccine-producing countries and those in need. Additionally, the social impact of the pandemic was noted to foster community support initiatives and solidarity. Our findings will be useful for implementing measures to facilitate vaccine acceptance and strengthen trust in the health care system, health care professionals, and scientific perspectives, thus improving current vaccination coverage. Public health authorities should study and counteract antivaccine messages through social networks. Additionally, these insights could serve as a starting point for developing sociopolitical strategies to enhance vaccination management and address potential future pandemics or new vaccination campaigns.

Acknowledgments

This work was supported by Diputació de Lleida and Societat Catalana de Pediatria, and Asociación Española de Pediatria de Atención Primaria.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

AH-F, EA-B, WA, and MOB contributed to the study concept and research design and selected and reviewed the literature on vaccination. WA and JS participated in the acquisition, analysis, and interpretation of data. AH-F, EA-B, MOB, JS, WA, and PG participated in the writing and critical review of the manuscript and approved the final version.

Conflicts of Interest

WA is an associate editor for *JMIR Infodemiology*.

Abstract

Background: Cyber victimization exposes individuals to numerous risks. Developmental and psychological factors may leave some users unaware of the potential dangers, increasing their susceptibility to psychological distress. Despite this vulnerability, methods for identifying those at risk of cyber victimization within health care settings are limited, as is research that explores their experiences of cyber victimization. The purpose of this study was to analyze how users describe experiences of cyber victimization on the social media platform Reddit (Reddit, Inc) using data mining.

Objective: This study aimed to analyze and describe how users on Reddit describe and discuss their experience of cyber victimization using data mining and computational analysis of unsolicited data.

Methods: This computational qualitative study used data mining, Word Adjacency Graph (WAG) modeling, and thematic analysis to analyze discussions of Reddit users surrounding cyber victimization. Inclusion criteria included posts from 2012 to 2023 from subreddits r/cyberbullying and r/bullying. GPT-4 (OpenAI), an advanced artificial intelligence language model, summarized posts and assisted in cluster labeling. Posts were reviewed to remove irrelevant content and duplicates. User anonymity was maintained throughout the study.

Results: A total of 13,381 posts from 3283 Reddit were analyzed, with approximately 5.1% (n=678) originating between 2012 and 2018 and 94.9% (n=12,703) from 2019 to 2023. The WAG modeling approach identified 38 clusters, with 35 deemed to be relevant to cyber victimization experiences. Two clusters containing irrelevant material were excluded. Six overarching themes emerged: (1) psychological impact, (2) coping and healing, (3) protecting yourself online, (4) protecting yourself offline, (5) victimization across various settings, and (6) seeking meaning and understanding.

Conclusions: The study highlights the effectiveness of data mining and AI in analyzing large public datasets for qualitative research. These methods can inform future studies on risky internet behavior, victimization, and assessment strategies in health care settings.

KEYWORDS

cyber victimization; word adjacency graphing; cyberbullying; artificial intelligence; data mining; thematic analysis

Introduction

Cyber victimization refers to harmful experiences that occur through the internet, social media, or communication devices. These experiences are often psychologically distressing and have been linked to depression, anxiety, self-harm, and suicidal ideation [1-5].

Although well-documented as a public health concern [6,7], there are limitations in the research, including a lack of studies exploring cyber victimization from the perspectives of those who experience it. Traditional qualitative studies have contributed valuable insights into cyber victimization experiences [8,9] but are often limited by small sample sizes and researcher bias [10]. In addition, instruments to detect cyber victimization often have different methods for operationalization, using specific terms or providing brief descriptions of acts or experiences [11]. The terminology researchers use to define cyber victimization also may not align with the individual perceptions of the experience. For example, in 1 study [12], users provided more reliable responses when the term “cyber victimization” was used rather than “cyberbullying,” suggesting that language choices influence how participants relate to research prompts.

XSL•FO
RenderX

Data mining and computational qualitative analysis, which involves using computer algorithms and software to collect and analyze qualitative data, is a novel method for understanding cyber victimization. This method has been successfully used to study various public health issues such as substance abuse [13], epilepsy [14], and intimate partner violence [15].

By mining data from social media sites, researchers can access large-scale data that reflect participants' genuine, organic thoughts, feelings, and discussions. Analyzing this user data can reveal patterns and trends that are not apparent using traditional research methods. This information can then be used to inform the development and implementation of interventions tailored to a specific population's unique experiences and needs.

In this study, we applied data mining and computational qualitative analysis to explore how individuals describe and discuss their experience of cyber victimization on the social media platform Reddit (Reddit, Inc). Our aim was to identify patterns and themes in unsolicited narratives. The findings of this study will inform future interventions and improve methods for identifying and supporting individuals who experience cyber victimization.

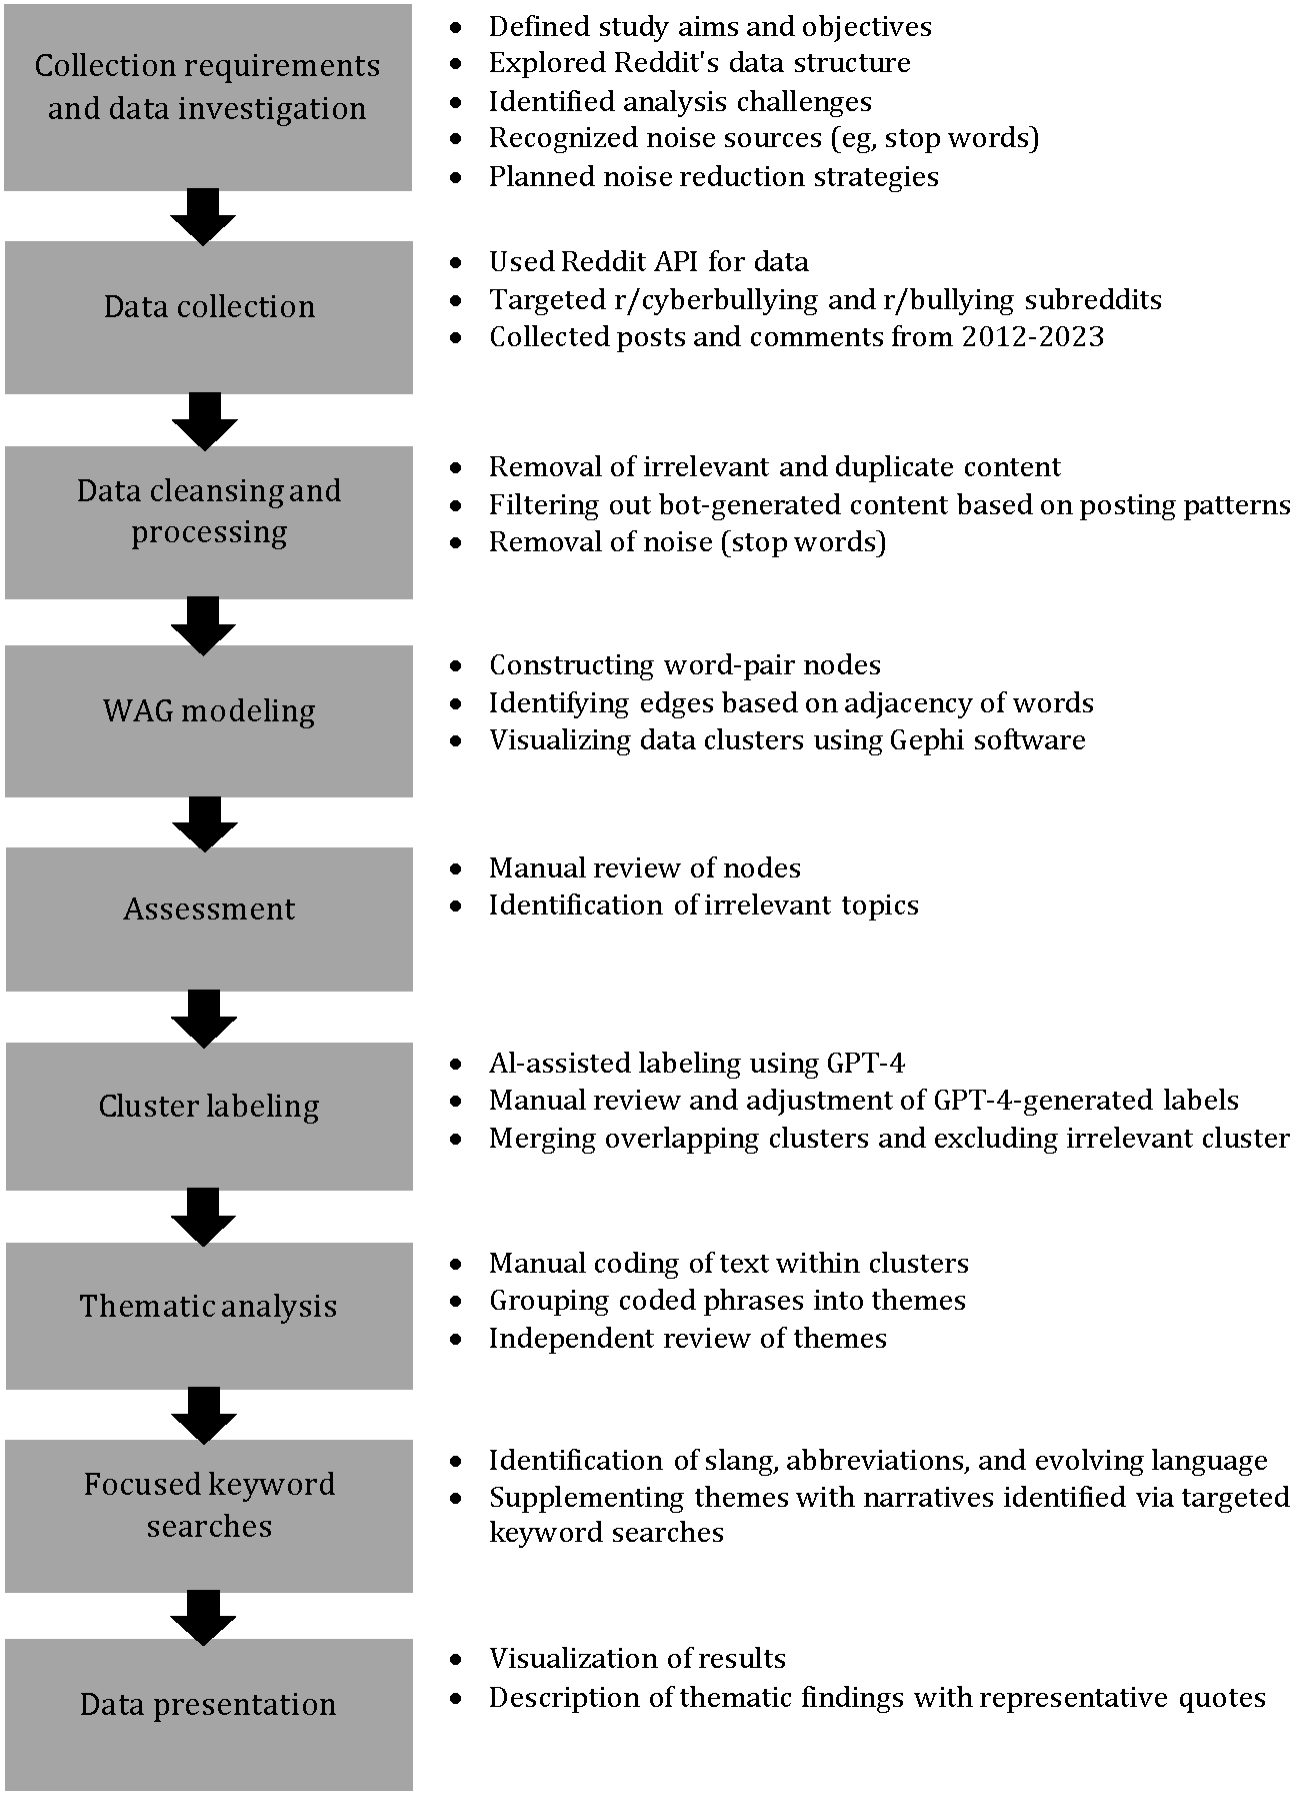
Methods

Study Design Overview

This qualitative computational analysis used data mining and Word Adjacency Graph (WAG) modeling [16] to examine cyber victimization narratives shared by users on Reddit. Data were collected from 2 subreddits, r/cyberbullying and r/bullying, over an 11-year period (2012 - 2023) to capture relevant trends and patterns in discussions surrounding cyber victimization. A systematic data extraction process was conducted using Reddit's application programming interface (API) and a custom web-scraping tool to gather posts and comments. After data cleaning to remove irrelevant duplicates and bot-generated content, WAG modeling was applied to identify patterns and thematic clusters within the text. Following cluster identification, GPT-4 (OpenAI) was used to generate preliminary labels and summaries, which were then manually reviewed for accuracy. A keyword searching process was also conducted to account for evolving language, slang, and abbreviations. Finally, a thematic analysis was performed to refine clusters into relevant themes.

Study Setting and Population

Reddit is a widely used social media and news aggregate platform with over 50 million active users [17]. It is known for its anonymous membership, allowing users to share their thoughts and opinions without revealing their identity. The platform is divided into over 10,000 "subreddits" with a wide range of topics, from current events and politics to hobbies and interests [18].



Although there are approximations regarding the age demographics of Reddit [19], Reddit does not collect demographic data, making it impossible to determine the exact demographic of users. Despite this limitation, Reddit has been used in previous research studies, providing valuable insights into mental health topics [20-22]. As demographic information cannot be verified, this study uses the term "users" to describe individuals who authored posts and comments. The study targeted subreddits r/cyberbullying and r/bullying for data mining, as these communities encourage personal discussions of cyber victimization. Data extraction focused on titles, post bodies, and comments from 2012 - 2023.

Data Mining and Computational Analysis

This study used data mining and WAG modeling [16] to examine discussions on Reddit about cyber victimization. Data mining was first conducted, followed by WAG modeling, to reveal patterns and relationships between words and concepts and identify common themes within the text. Data mining consultations were conducted to enhance the validity and to confirm that the process was in alignment with the aim of the study, which was to analyze how users on Reddit describe and discuss their experience of cyber victimization. Following a systematic approach [23], data mining comprised 6 stages: collecting requirements, data investigation, data collection, modeling, assessment, and presentation [24-30]. These are outlined in Multimedia Appendix 1. A visual overview of the full methodological process is provided in Figure 1, and the topic detection process using WAG modeling is illustrated in Figure 2.

Figure 2. Topic detection via Word Adjacency Graph modeling.

Thematic Analysis of Clusters

Following labeling, clusters were thematically analyzed with MAXQDA 2022 (VERBI Software GmbH), a qualitative data management software program [29], to organize clusters into overlapping themes. The full dataset was organized and prepared in a Microsoft Excel document, arranged by cluster, as well as into categories of weak clusters and those not fitting into any cluster. Each post or comment within the clusters was assigned an individual identification number. For example, when a post or comment is the 61st data point within cluster 4, it would be labeled as "C4-61."

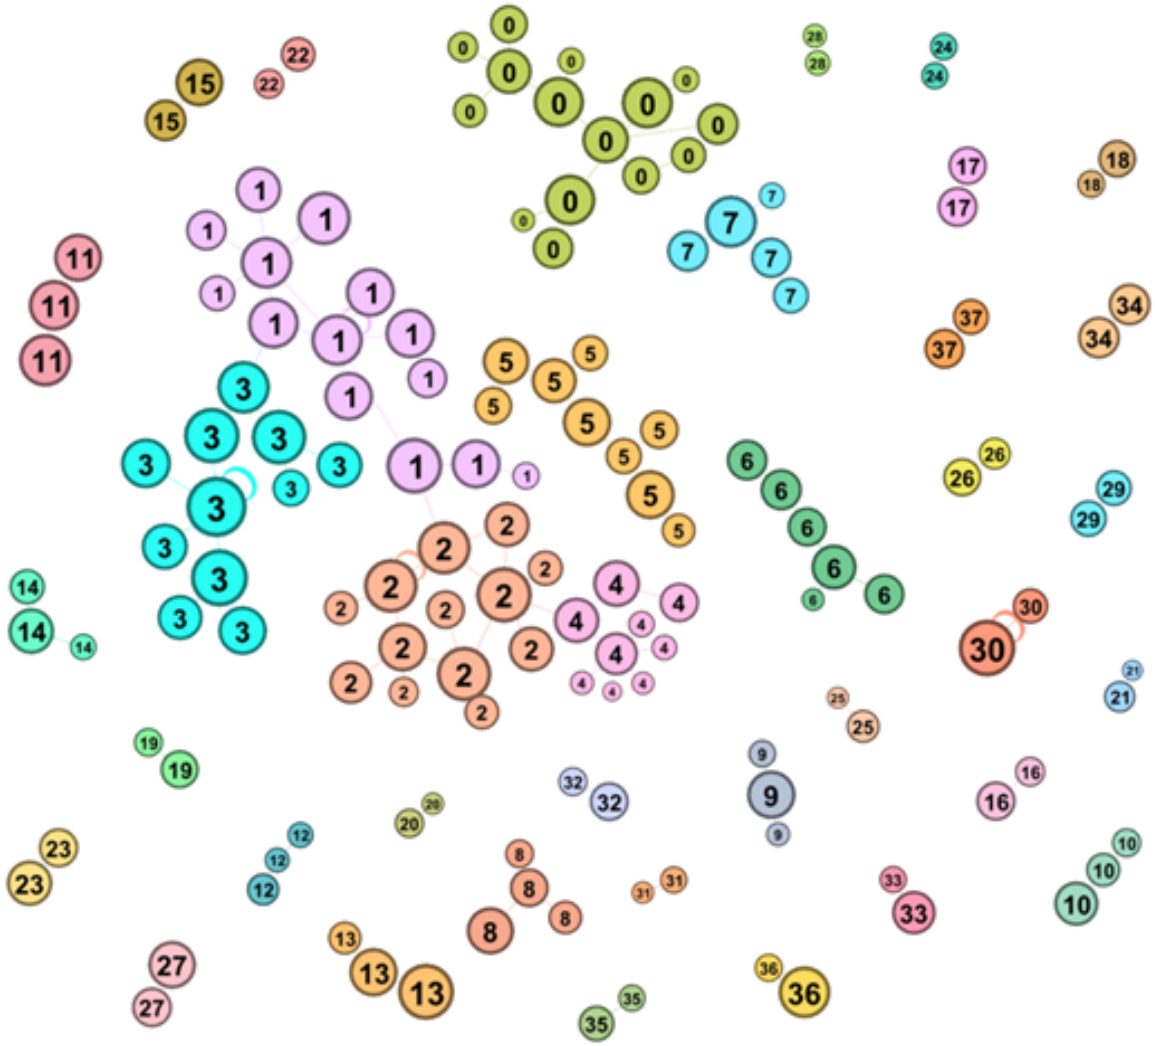
Posts and comments organized by cluster were transcribed into MAXQDA and coded with key phrases based on the content and context. Phrases that were similar in context were grouped and organized into themes. Following the categorization of the clusters into themes, another researcher independently reviewed these themes to ensure accuracy and consistency. This review process involved a thorough examination of how the themes were derived, ensuring that they accurately reflected the key phrases and context from the original posts and comments. The reviewer also assessed the alignment of the themes with the overall objectives of the study, adjusting where necessary to address any discrepancies or oversights.

Ethical Considerations

This study was reviewed by the Institutional Review Board at Indiana University and determined to be exempt under category 4(i): publicly available information or specimens (Protocol #18415; initial approval February 28, 2023). The exemption was granted because the research involved analysis of publicly accessible Reddit posts without direct interaction with human subjects. Informed consent was not sought, as the data were unsolicited, publicly available, and collected in accordance with established guidelines for internet-based research on publicly accessible content without user interaction, as outlined by Eysenbach and Till [31]. To protect privacy and confidentiality, no usernames, profile information, or other potentially identifying details were stored or reported, and example quotes were paraphrased when necessary to minimize traceability via search engines. All electronic data were collected and stored on encrypted devices. Data collection complied with Reddit's API access policies [32]. Funding for this research was made possible (in part) by Grant Number 5H79SM080386-05 from the Substance Abuse and Mental Health Services Administration (SAMHSA).

Results

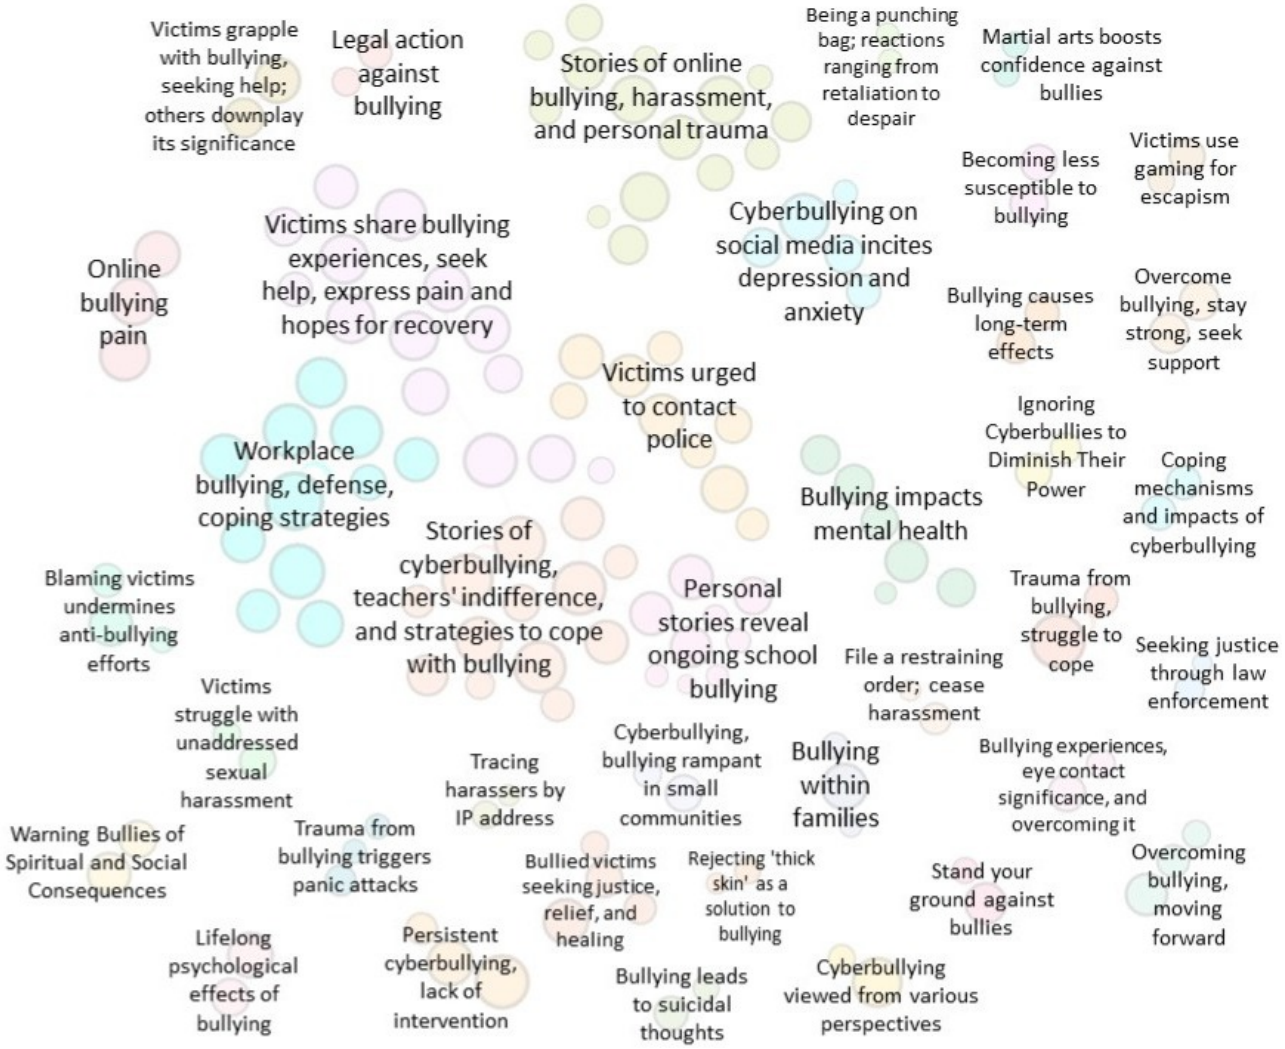
Overview



This study successfully applied data mining, WAG modeling, GPT-4–assisted labeling, and thematic analysis to examine cyber victimization narratives shared by users on Reddit. The extracted dataset comprised 13,381 posts and comments from 3283 unique Reddit users. Approximately 5.1% (n=678) of the posts were posted between 2012 and 2018. The remaining 94.9% (n=12,703) of the posts were posted to Reddit from 2019 - 2023.

To construct the WAG model, only words and word pairs appearing more than 10 times were included, resulting in 150 unique words and 123 word pairs for analysis. As a result, 15% (n=1965) of posts and comments were strongly categorized, 62% (n=8290) were weakly categorized, and 23% (n=2984) were not fitted into the model. The posts that were strongly categorized formed the basis of the 38 clusters (Figure 3), which were then visualized using Gephi (Gephi Consortium). In this visualization, each node represents a word pair, with node size reflecting word frequency and proximity to similar words. Of the 38 clusters, 35 were relevant to cyber victimization experiences, while 2 clusters were excluded due to irrelevance. In addition, the WAG modeling process placed the word pairs of "law enforcement" and "legal action" into 2 clusters, but due to their overlapping content, they were merged into a single cluster (Figure 4).

XSL•FO
RenderX



The distribution of posts and comments across clusters varied, with some clusters containing a high volume of discussion while others had minimal engagement (Multimedia Appendix 2). Clusters 1 and 2 had the highest number of posts and comments, followed by clusters 3 and 0. Some clusters contained fewer than 20 posts and comments, indicating less frequent discussion of those themes. A full list of cluster labels and their thematic categorization is provided in Multimedia Appendix 3.

Figure 3. Word Adjacency Graph results cluster numbers.

XSL•FO
RenderX

Figure 4. Word Adjacency Graph results cluster labels.

Cluster Labeling and Validation

All Clusters were manually reviewed and excluded from the model in instances in which users were identified as automated bots or where posts consisted of research recruitment by researchers. The analysis involved screening for data skewness caused by the overrepresentation of individual users. This occurred in situations where users repeatedly posted similar content, which artificially inflated the presence of certain themes or topics in the dataset. Such repetitive postings, not indicative of genuine user interactions, were identified and excluded to ensure the integrity and representativeness of the data.

In analyzing online interactions and narratives surrounding cyber victimization, GPT-4 was initially used to label the resulting 38 clusters (see Multimedia Appendices 2–3,4). GPT-4 synthesized a subset of posts and comments from each cluster to generate suggestive labels. The mean number of posts per cluster was 22 (SD 1) , with a typical range of 13 - 30 posts; the smallest cluster included 7 posts, and the largest contained 44. These sample sizes were shaped by technical limitations at the time of the study (2023) when the GPT-4 model's context window restricted how much data could be processed at once. At that time, approximately 819 (40%) posts of the total cluster data were used in GPT-4–assisted label generation.

Each suggested label was subsequently evaluated by a human reviewer. The manual review process relied on five validation categories: (1) retained, (2) adjusted, (3) revised, (4) merged, and (5) excluded, which were applied based on how closely the GPT-4 suggested label aligned with the cluster data. As a result, 12 labels were retained with only minimal word changes, 12 labels were adjusted, meaning the suggested label generally matched the content but required rewording to improve clarity or reflect the data more accurately, and 10 labels were completely revised to align with the content of the posts. Two clusters were merged due to thematic overlap, and 2 were excluded from the analysis due to irrelevance (see Multimedia Appendix 4).

To enhance interpretive rigor, a secondary researcher reviewed all cluster labels and confirmed their alignment with the underlying post content and resulting themes. While formal interrater reliability metrics were not calculated, consensus was achieved through collaborative review and discussion.

Overall, GPT-4 provided a usable starting point for 36 out of 38 clusters (94.7%), with 26 clusters (68%) requiring some degree of human refinement. Definitions and illustrative examples of each validation category are provided in Multimedia Multimedia Appendix 5.

XSL•FO
RenderX

Focused Keyword Searching

Focused keyword searching was used to expand the analysis of clustered data and improve the identification of themes. This approach involved reviewing the narratives within each cluster to identify key concepts, expressions, or themes. From these, related terms and alternative phrasings were generated and used as targeted search terms across the dataset. For example, a narrative discussing a specific form of cyberbullying, like blackmail, would lead to the identification of related terms such as "blackmail" and "catfish" (Multimedia Appendix 6). This strategy allowed for the identification of narratives that were weakly clustered or not clustered at all due to variations in words or phrasing. The total number of posts retrieved via focused keyword searching was not tracked. However, the process did lead to the identification of additional narratives that were thematically aligned but not strongly categorized. These supplemental posts helped confirm existing themes and broader representation of experiences.

Thematic Analysis

Following labeling, clusters were thematically analyzed with MAXQDA 2022, a qualitative data management software program [29], to organize clusters into overlapping themes. Posts and comments organized by cluster were transcribed into MAXQDA and read and coded with key phrases based on the content and context. Phrases that were similar in context were grouped and organized into themes.

As a result of this analysis, six themes emerged: (1) psychological impact, which examines the symptoms of cyber victimization; (2) coping and healing, focusing on healing and overcoming cyber victimization and seeking support; (3) protecting yourself online, highlighting methods for preventing or stopping cyber victimization; (4) protecting yourself offline, detailing methods to decrease the risk of being targeted in the physical world; (5) victimization across various settings, exploring the dynamics of victimization in different environments; and (6) seeking meaning and understanding, which includes philosophical discussions about the nature of victimization. A summary table outlining each theme with supporting subtopics is provided in Multimedia Appendix 7. A detailed thematic analysis of the qualitative findings will be presented in a separate publication where the themes will be explored in-depth, along with direct quotes and case examples.

Discussion

Principal Findings

This study identified 6 overarching themes in Reddit posts related to cyber victimization: psychological impact, coping and healing, protecting oneself online, protecting oneself offline, victimization across various settings, and seeking meaning and understanding.

By following a structured, hybrid analytic process [Figure 1] combining data mining, WAG modeling, and GPT-4–assisted labeling, this study demonstrates the effectiveness of computational qualitative methods in analyzing large-scale, unsolicited data on cyber victimization. This approach addressed the limitations of traditional qualitative research, especially in the context of handling large amounts of unstructured data. In addition, traditional qualitative research methods are often limited by participant selection biases and social desirability biases, which limit the breadth and depth of the narratives [10]. The anonymity of Reddit also encouraged users to share sensitive information without fear of stigma. This approach facilitated the identification of patterns and emerging themes that may not have been captured through manual coding alone.

This study provided a novel methodological approach for examining cyber victimization experiences and highlights the potential for AI-assisted qualitative analysis. GPT-4 was used in initial cluster labeling, which, when combined with manual review, improved the accuracy of thematic categorization. This builds on previous qualitative research by demonstrating how computational tools can be applied to analyze unsolicited narratives, reduce researcher bias, and identify themes across a vast dataset.

While hybrid computational-qualitative methods have been applied to topics such as substance abuse [13], epilepsy [14], and intimate partner violence [15], this study extends that work by applying similar techniques to cyber victimization. By doing so, it demonstrates the adaptability of WAG modeling and GPT-4–assisted labeling to new areas of public health. Recent studies support this hybrid approach. For example, Piper and Wu [33] found that large language models (LLMs) performed well in narrative topic labeling, while Castellanos et al [34] demonstrated that although GPT-4 generated themes aligned with human coding in over 79% of cases, human coders were still required for accuracy. Our integration of GPT-4–assisted labeling with manual review aligns with these findings and demonstrates the need for human oversight.

The findings have practical implications for health care settings. Recognizing the diverse ways users describe psychological impacts and coping strategies could inform the development of educational resources, screening instruments, and assessment strategies that reflect the language and experiences of victims. These resources would be valuable to health care professionals in identifying individuals at risk in primary care or mental health settings where cyber victimization may go unreported.

Limitations

While this study has many strengths, it is not without limitations. Our data consisted of anonymous user narratives from Reddit, making it challenging to determine the generalizability of the sample to a wider population. Reddit users also may have specific characteristics, interests, or behaviors that are not reflective of a broader population [35]. In addition, social media platforms have distinct user demographics and cultures, which might influence the nature and extent of cyber victimization experienced by users. For example, Reddit users are more likely to be men [36,37], while TikTok (ByteDance Ltd), Facebook (Meta Platforms), and Pinterest (Pinterest, Inc) users are more likely to be women [37].

Due to the inability to follow up with users for explanation and clarification and the inability to meet users face-to-face to assess body language, vocal tones, and facial expressions, there was a potential for misinterpretation of context [38]. The anonymous

XSL•FO
RenderX

nature of Reddit may also lead to false answers or misinformation, as internet-based platforms can be prone to exaggeration, false claims, or recall bias. In addition, demographic inferences cannot be made, as users are not required to disclose personal information.

An important limitation of this research is the potential inclusion of bot-generated content [39]. Despite efforts to identify and exclude bots based on patterns in posting behavior, timing, frequency, language use, and identifiable usernames, the sophisticated nature of some bots may have allowed them to bypass detection. It is possible that bot-generated posts, which do not reflect human experiences, were incorporated into the dataset, potentially influencing the results.

Another limitation relates to the evolving nature of LLMs. GPT-4, the model used at the time of this study (2023), had a significantly smaller context window, which limited the number of posts that could be processed per cluster. As a result, only a subset of cluster content was used for label identification. Newer versions of the model support much larger input sizes, which may produce different results, affecting replication in future studies.

Finally, while GPT-4 accelerated the qualitative analysis process, several limitations must be acknowledged. LLMs are prone to selective summarization and misrepresentation, known as hallucination [40]. LLMs may also simplify content while being overconfident in tone, which can influence researchers' judgment by making inaccurate or biased content appear more credible than it is. These limitations may have affected the accuracy of cluster label identification. Manual validation was used to mitigate these risks. However, the reliance on GPT-4 for suggestive labeling remains a methodological limitation worth noting.

Implications for Further Research

Future research could expand this methodology to further explore and deepen the understanding of cyber victimization experiences and further refine computational qualitative analysis techniques. While this study focused on cyber victimization experiences in 2 subreddits, other communities may provide further insight into cyber victimization. Future studies could extend data mining and WAG modeling to specific types of cyber victimization-related subreddits such as r/stalking, r/cyber security, and r/scams, which focus on distinct aspects of harmful experiences. Cyber victimization is broad; these specific subreddits could provide a more nuanced understanding of how different forms of cyber victimization are discussed within internet-based communities.

To explore how cyber victimization experiences vary across internet-based spaces with different user demographics and privacy structures, future research could compare narratives from different platforms (TikTok [ByteDance Ltd], Discord [Discord Inc], Bluesky [Bluesky PBLLC], Instagram [Meta Platforms], and Tumblr [Automattic]). Each platform has unique privacy settings, user demographics, and moderation policies, which may influence how users discuss and experience cyber victimization.

Conclusions

This study used a hybrid methodological approach to analyze how users on Reddit describe their experience of cyber victimization using data mining and computational analysis of unsolicited data. By leveraging data mining and WAG modeling, this study demonstrated the effectiveness of computational methods in qualitative analysis. GPT-4-assisted labeling and focused keyword searching further refined thematic identification, resulting in 6 themes: psychological impact, coping and healing, protecting oneself online, protecting oneself offline, victimization across various settings, and seeking meaning and understanding. The methodological approach demonstrated in this study will be valuable to data scientists and health care researchers seeking to analyze social media data on mental health issues. These methods can inform future studies on risky internet behavior, victimization, and assessment strategies in health care settings.

Abstract

Background: There has been an increase in the prevalence of noncommunicable diseases in Malaysia. This can be prevented and managed through the adoption of healthy lifestyle behaviors, including not smoking, avoiding alcohol consumption, maintaining a balanced diet, and being physically active. The growing importance of using social media to deliver information on healthy behaviors has led health care professionals (HCPs) to lead these efforts. To ensure effective delivery of information on healthy lifestyle behaviors, HCPs should begin by understanding users' current opinions about these behaviors and whether the users are receptive to recommended health practices. Nevertheless, there has been limited research conducted in Malaysia that aims to identify the sentiments and content of posts, as well as how well users' perceptions align with recommended health practices.

Objective: This study aims to examine social media posts related to various lifestyle behaviors, by using a combination of sentiment analysis to analyze users' sentiments and manual content analysis to explore the content of the posts and how well users' perceptions align with recommended health practices.

Methods: Using keywords based on lifestyle behaviors, posts originating from X (formerly known as Twitter) and published in Malaysia between November and December 2022 were scraped for sentiment analysis. Posts with positive and negative sentiments were randomly selected for content analysis. A codebook was developed to code the selected posts according to content and alignment of users' perceptions with recommended health practices.

Results: A total of 3320 posts were selected for sentiment analysis. Significant associations were observed between sentiment class and lifestyle behaviors (χ^2_6=67.64; P<.001), with positive sentiments higher than negative sentiments for all lifestyle behaviors. Findings from content analysis of 1328 posts revealed that most of the posts were about users' narratives (492/1328), general statements (203/1328), and planned actions toward the conduct of their behavior (196/1328). More than half of tobacco-, diet-, and activity-related posts were aligned with recommended health practices, whereas most of the alcohol-related posts were not aligned with recommended health practices (63/112).

Conclusions: As most of the alcohol-related posts did not align with recommended health practices, the findings reflect a need for HCPs to increase their delivery of health information on alcohol consumption. It is also important to ensure the ongoing health promotion of the other 3 lifestyle behaviors on social media, while continuing to monitor the discussions made by social media users.

Introduction

Noncommunicable diseases (NCDs) have become a significant global health challenge, accounting for 74% of all deaths worldwide [1]. NCDs have also become a growing public health concern in middle-income countries within the Southeast Asia region. Malaysia is one of the countries in the region that has been significantly impacted by NCDs, with over 67% premature NCD-related mortality and over 70% disease burden [2]. Approximately, 2.5% of Malaysian adults, which accounts for over half a million people were affected by all 4 major NCDs, which are diabetes, hypertension, hypercholesterolemia, and obesity [3].

The World Health Organization (WHO) has identified 4 key modifiable risk factors associated with an elevated risk of NCDs, which are tobacco smoking, harmful use of alcohol, unhealthy diet, and physical inactivity [1,4]. The adoption of healthy lifestyle behaviors, including not smoking, avoiding alcohol consumption, maintaining a balanced diet, and being physically active can reduce modifiable risk factors, effectively preventing and managing NCDs. However, national surveys have indicated that the actual adoption of healthy behaviors among Malaysians remains low. For example, over 84% of Malaysian adults were inactive in sports, with half of the population leading a sedentary lifestyle, spending more than 2 hours sitting while awake [3].

In this regard, it is important to deliver information on healthy lifestyle behaviors, with health care professionals (HCPs) being ideally positioned to lead these efforts. Various technologies, such as mHealth applications, wearable devices [5], and social media platforms, can support the delivery of health information. Social media platforms have been widely used for health information delivery as these platforms are accessible to larger populations at a lower cost [6,7]. To effectively promote healthy lifestyle behaviors on social media, HCPs could begin by understanding users' current opinions on lifestyle behaviors and whether they are receptive to recommended health practices [8]. This could be achieved by examining social media posts discussing on lifestyle behaviors. X (formerly known as Twitter) is one of the microblog-based social media platform that allows users to freely express their opinions through posts, previously referred to as tweets. As of January 2024, approximately 5.71 million social media users in Malaysia were on X, accounting for 16.5% of the country's population [9], which highlights the growing popularity of X among Malaysians.

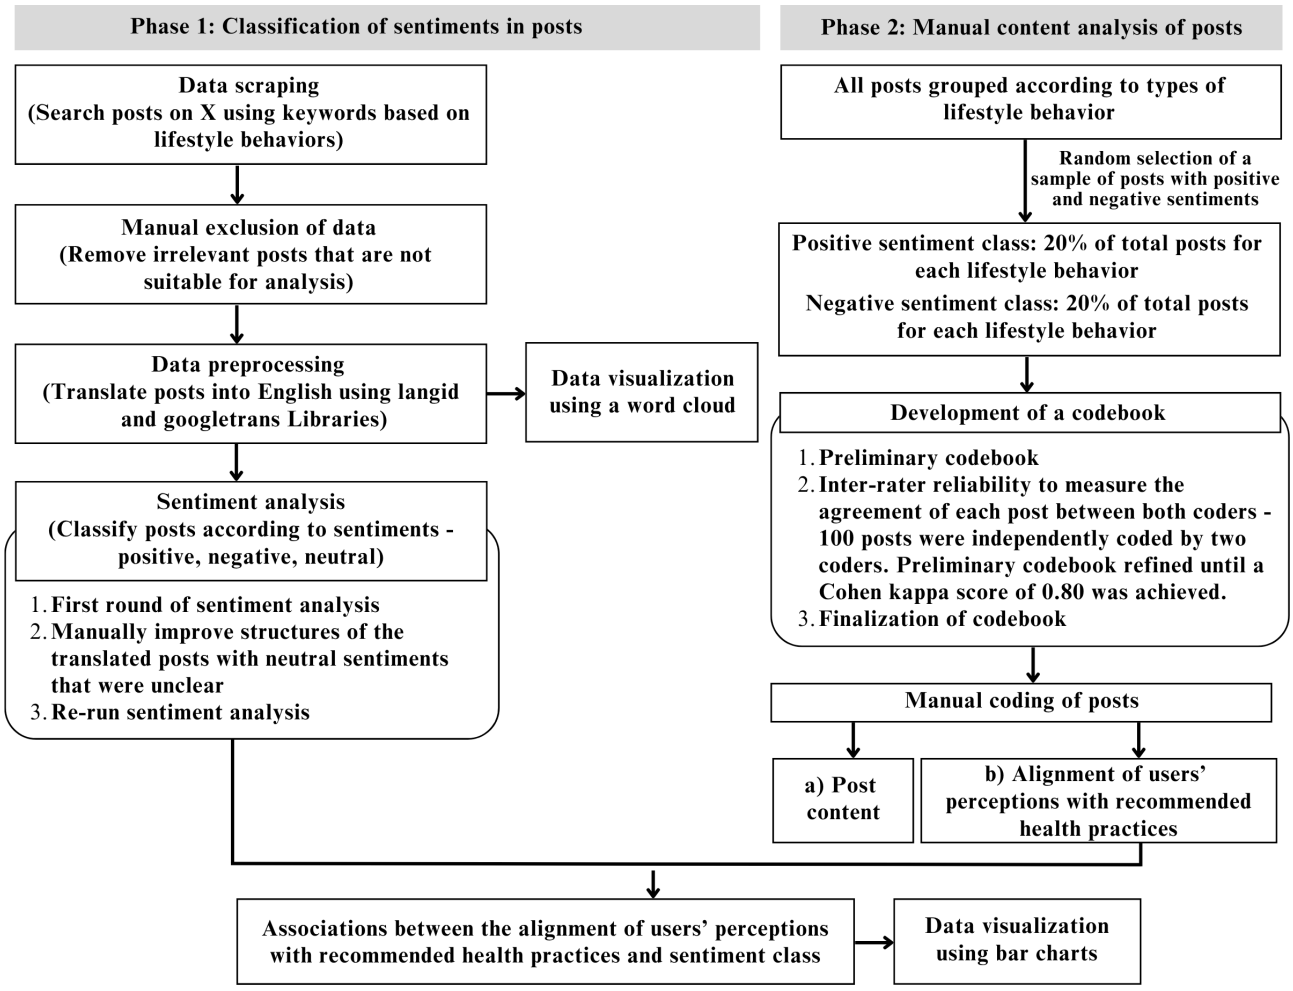
When users express their opinions in writing on social media, a range of emotions may be conveyed. Sentiment analysis is the process of classifying this textual data based on the emotions conveyed within the text as positive, negative, or neutral sentiments [10]. It can be conducted through manual annotation of posts or computational approaches [11]. Computational approaches in sentiment analysis are preferred as they are more cost-efficient, and can leverage large amounts of publicly accessible and concise real-time data across different regions and demographics [12]. Methodologies of computational approaches include lexicon-based sentiment analysis, which uses pre-existing dictionaries containing words with pre-assigned sentiment scores of positive, negative, or neutral. Lexicon-based sentiment analysis is effective when limited labelled training data is available with a strong association of sentiments with specific words. The usage of this approach has been documented in numerous studies that analyze sentiments regarding lifestyle behaviors such as the examination of policies on electronic cigarettes [13], vegan-related posts [14], and organic food posts [15].

Lexicon-based sentiment analysis, however, may have limited coverage in terms of vocabulary and often misses sarcasm or irony [16]. Positive sentiments may not necessarily translate to good health practices and vice versa. For example, the sentence "I love tobacco" showed positive sentiments, but the actual context is related to the user's preference towards unhealthy lifestyle behaviors. In order to further understand the topics communicated on social media and how users' perceptions are aligned with recommended health practices, lexicon-based sentiment analysis can be supported with manual content analysis. A codebook can be used to manually assign labels to each post, which will provide a more in-depth analysis of the posts [17].

The examination of social media posts across multiple lifestyle behaviors of tobacco smoking, alcohol consumption, diet, and physical activity could facilitate effective comparisons of findings across these different behaviors. The use of such findings would enable HCPs to use social media to deliver information on healthy behaviors by targeting areas where the lifestyle behaviors are not aligned with recommended health practices. Analyses that are focused within a geographic location would provide opportunities for HCPs to prioritize region-targeted health information delivery on social media. Such health information could also potentially be replicated in other countries with similar digital and health ecosystems.

Nevertheless, there have been limited studies that used the combined approaches of lexicon-based sentiment and content analysis to examine social media posts on lifestyle behaviors. The majority of the available studies were focused on other health-related issues such as the examination of users' perceptions on diabetes [18] and marijuana usage [19]. A study by Kasson et al [20] have used both sentiment analysis and manual content analysis to examine users' vaping behaviors. However, the study was confined to vaping behaviors during the e-cigarette or vaping use-associated lung injury outbreak and did not address other lifestyle behaviors. In addition, there is a lack of studies examining the opinions of social media users in Malaysia on lifestyle behaviors, despite the increasing burden of NCDs and the rising prevalence of unhealthy lifestyle behaviors in the country.

Therefore, this study used a combination of lexicon-based sentiment analysis and manual content analysis to understand the discussions on lifestyle behaviors among social media users in Malaysia. This study had three objectives: (1) to determine the sentiments of social media users in Malaysia regarding lifestyle behaviors, (2) to identify the content of posts and ascertain if users' perceptions were aligned with recommended health practices, and (3) to explore the associations between the alignment of users' perceptions with recommended health practices and sentiment class.



XSL•FO
RenderX

Methods

Overview

Figure 1 shows the overall study methods. In the classification of sentiments in posts, data was scraped from X. Following the manual exclusion of irrelevant posts, the data was cleaned, preprocessed and analyzed for sentiments. Data visualization was subsequently conducted. In the manual content analysis of posts, a random selection of posts with positive and negative sentiments for each lifestyle behavior was manually coded to identify the content of posts and the alignment of users' perceptions with recommended health practices. Associations between the alignment of users' perceptions and sentiment class were subsequently explored.

Figure 1. Overall study methods.

Classification of Sentiments in Posts

Data Scraping

The automated process of extracting large amounts of data from X is known as data scraping. All posts with keywords related to the 4 lifestyle behaviors aimed at reducing the 4 key modifiable risk factors for NCDs were scraped. These keywords are related to tobacco and its derivative products, alcohol, dietary, and physical activity. The 4 sets of keywords are provided in Multimedia Appendix 1. The keywords were derived from published systematic reviews on the management of lifestyle behaviors using social media [21,22]. Additional keywords commonly used locally were added upon discussion with all researchers.

Posts spanning 2 consecutive months were selected. This time frame was deemed to be appropriate, as similar studies analyzing health-related sentiments on the X platform have also utilized data across a 2-month period [23,24]. The selection of the 2 consecutive months was conducted by initially scraping all posts from January to December 2022 according to each month. The 2 months with the highest number of posts were from November to December 2022. Post based in Malaysia were determined using longitude and latitude metadata (4.2105°N, 101.9758°E). In terms of language, posts in Malay and English were scraped. Malay is the national language of Malaysia, whereas English is widely spoken and understood by Malaysians. They also use a mix of both languages, resulting in multilingual data.

Data scraping was conducted separately for each set of keywords using the SNScrape library on Python. In addition to posts, other X metadata such as timestamp, X username, number of reposts, language, and location were also collected.

Manual Exclusion of Data

All posts were manually screened by 2 researchers to exclude those not suitable for analysis, with discrepancies resolved among the research team. The exclusion steps were as follows:

XSL•FO
RenderX

First, the exclusion of posts not from Malaysia—During data scraping, longitude and latitude data retained posts located within the coordinates but posted outside of Malaysia, such as parts of Singapore and Thailand. The "location" metadata was therefore used to manually exclude these posts.

Second, the exclusion of irrelevant posts—Irrelevant posts include posts with different definitions (eg, "exercising" your rights), posts not related to health care (eg, religious restrictions on alcohol), indecipherable posts and posts made by bots. Bots were verified by manually checking the user's profile for any unusual activity patterns that exhibited automated behavior (eg, high frequency of posts without breaks).

Data Preprocessing

Before conducting sentiment analysis, data preprocessing was carried out to ensure that the text data was cleaned, transformed, and prepared for analysis.

The model selected for sentiment analysis was the Valence Aware Dictionary and Sentiment Reasoner (VADER) on Python. It is a lexicon-based sentiment analysis tool [25] that is suitable for analyzing social media posts, generating results with high classification success [26]. As VADER is trained for sentiment analysis in English, all posts in Malay and mixed languages were preprocessed and translated into English using the langid and googletrans libraries on Python.

Other data preprocessing steps (tokenization, lower casing of texts, removal of stop words, html links, numbers, punctuations, emojis, and acronyms) were not executed. This is attributed to the unique advantages of VADER, in which assessment scores would account for capitalism, punctuations, emojis, English acronyms (eg, "LOL"), and colloquialisms (eg, "meh") [27-29].

Following data preprocessing, a word cloud used to provide a visual representation of the words in the overall X dataset.

Sentiment Analysis

Computational, lexicon-based sentiment analysis was conducted to determine users' sentiments. This approach was selected over manual annotations and other types of computational methods as it is cost-effective and does not require training for large datasets. As it relies on a predefined lexicon, it does not require significant computational resources. For general sentiment analysis, lexicon-based approaches often performs well enough to capture the overall sentiment trends in social media data [25].

The posts that have undergone data preprocessing were then analyzed for polarity using VADER. VADER classifies posts into positive, neutral, and negative sentiments. Positive sentiments have a compound score of ≥0.05, neutral sentiments have a score between >−0.05 and<0.05 and negative sentiments have a score of ≤−0.05 [25].

Computer-assisted translation tools may limit the extent of translation in posts that contain local dialects and slang. The translated posts may become indecipherable, causing them to be classified as having "neutral" sentiments. For example, "x" in Malay, which means "no" in English may not have undergone translation, resulting in sentiments not being classified accurately. Following the first round of sentiment analysis, the structures of the translated posts that were unclear and yielded neutral sentiments were manually improved. The sentiment analysis was then re-run to enhance the robustness of sentiment classification and to reduce the inaccurate labeling of posts.

Manual Content Analysis of Posts With Positive and Negative Sentiments

Sentiment analysis classifies texts according to the emotions conveyed [10]. However, there was no further elaboration on the content and whether users' perceptions were aligned with recommended health practices.

Therefore, a sample of posts with positive and negative sentiments were randomly selected for manual content analysis. Stratified sampling was conducted by dividing the posts according to the type of lifestyle behavior and sentiment class (positive or negative). For each type of lifestyle behavior and sentiment class, 20% of the total posts for the particular lifestyle behavior were subjected to random selection. This would allow the posts for each lifestyle behavior to have an equal number of positive and negative sentiments. The random sample of posts was generated by using the random number equation in Microsoft Excel relative to the ID number attached to each post. This approach was adopted from a previous content analysis study on X, which also manually coded a random sample of 20% of total posts [30].

A preliminary codebook with 2 categories was developed through discussions among the research team to classify the content of posts and the alignment of users' perceptions with recommended health practices. This codebook is partially adapted from the codes used by Miller et al [31]. The recommended health practices are based on WHO's health recommendations [32]. In brief, WHO advocates healthy practices, including abstaining from smoking and alcohol consumption, maintaining a balanced diet, and engaging in regular physical activities. The codes were mutually exclusive. Using the preliminary codebook, 100 posts (25 posts for each type of lifestyle behavior) were independently coded by 2 coders. Interrater reliability was conducted to measure the agreement of each post between both coders. The preliminary codebook was refined until a Cohen kappa score of 0.80 was achieved. The remaining posts were then coded independently using the finalized codebook by both coders.

Table 1 provides a brief description of the codes for the finalized codebook, with a more comprehensive codebook provided in Multimedia Appendix 2.

XSL•FO
RenderX

Table . Brief description of codes.

Category	Definition
Post content (Topical content dealing with the lifestyle behavior mentioned in the post)	
Self-narrative of current lifestyle behaviors	Narration of self's current lifestyle behaviors.
Narrative of others' current lifestyle behaviors	Talked about other people's current lifestyle behaviors.
Planned action related to lifestyle behaviors	A planned action that will be conducted by the person who wrote the post.
Recommendations related to lifestyle behaviors	A recommendation by the person who wrote the post, providing instruction, advice, or suggestion to others.
Direct question	Direct question used in a post.
General statement	General statement that is not under any of the other categories above.
Alignment of users' perceptions with recommended health practices (Whether users' perceptions in posts are aligned with WHO's health recommendations)	
Aligned with recommended health practices	Users agreed with the conduct of recommended health practices, that included not smoking, avoiding alcohol consumption, maintaining a balanced diet and being physically active.
Not aligned with recommended health practices	Users were not agreeable with the conduct of recommended health practices (eg, consumed oily food, refused to exercise).
Users' perceptions cannot be defined	The perceptions of the user could not be defined or linked with health practices.

Data Analysis

Data analysis was performed using descriptive statistics with all variables expressed in frequencies and percentages. The Pearson chi-square test was used to compare the associations between the categorical variables, with *P* values <.05 considered to be statistically significant. IBM SPSS Statistics version 26.0 was used for data analysis.

Findings were also visualized using a word cloud and bar charts. In addition, examples of posts were provided to describe the study findings.

Ethical Considerations

This study was approved by the Medical Research and Ethics Committee, Ministry of Health Malaysia (NMRR ID-23 - 00293-CIM [IIR]) on March 23, 2023, and the Research Ethics Committee, Universiti Kebangsaan Malaysia (UKM PPI/111/8/JEP-2023 - 174) on April 13, 2023.

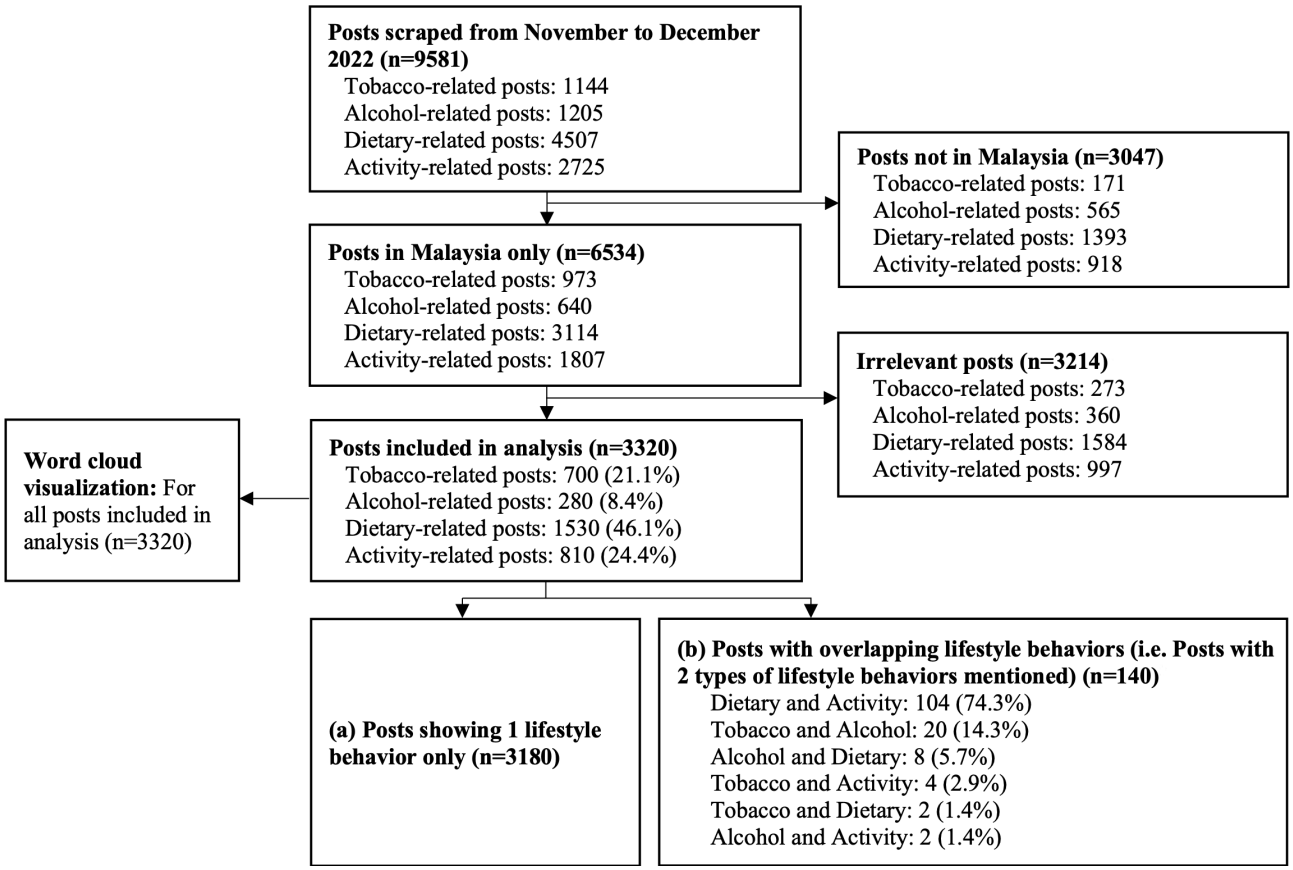
As this study relied solely on publicly available social media data on X and did not involve direct interaction with individuals, informed consent was not applicable. No compensation was offered or provided, as the study did not involve direct participation of human participants.

No identifiable private user information was collected or analyzed. All data used in the analysis were publicly available and did not contain personally identifiable information.

Results

Overview of X Dataset

Figure 2 shows the flowchart of the selection of the X dataset.



A total of 9581 posts were scraped from November to December 2022. Following the exclusion of 3047 posts that were not in Malaysia and 3214 irrelevant posts, 3320 posts across 4 types of lifestyle behaviors were retained for sentiment analysis. Almost half of the posts were dietary-related (1530/3320, 46.1%), followed by activity-related (810/3320, 24.4%) and tobacco-related (700/3320, 21.1%) posts. Alcohol-related posts were present in only one-tenth of the posts (280/3320, 8.4%).

As data scraping was conducted separately for each lifestyle behavior, a post may appear more than two times across different behaviors. Out of the 3320 posts, 3180 (95.8%) posts showed 1 lifestyle behavior only. There were 140 posts with two types of lifestyle of behaviors mentioned, with three-quarters (104/140, 74.3%) of posts mentioning both dietary- and activity-related behaviors.

A word cloud was used to visualize the overall X dataset (n=3320; see Multimedia Appendix 3). Overall, the 5 terms most commonly mentioned by users were "diet," "rice," "eat," "sugar," and "smoke."

XSL•FO
RenderX

Figure 2. Flowchart of selection of X dataset. Examples of irrelevant posts include (1) tobacco-related posts: gaming-type of posts (eg, smoke mentioned in a game), music band names (eg, Cigarettes After Sex), tweet mentioning terms as a location (eg, Hookah Island, Vape Shop); (2) alcohol-related posts: banning alcohol due to religion with no links to health (eg, at Qatar for the World Cup), sarcasm-based (eg, "you must be drunk," which translates to "you must be kidding me"); (3) dietary-related posts: nephew in Malay (eg, anak buah), nonhealth posts (eg, fruit on the trees or plants, sugar daddy); (4) activity-related posts: posts mentioning terms as a location (eg, Sports Direct), nonhealth posts (eg, who will be Sports Minister?, "exercising" your rights). With regard to posts overlapping lifestyle behaviors, as data scraping was conducted separately for each lifestyle behavior, a post may appear more than 2 times across different behaviors (eg, the post talks about both smoking and dietary habits).

Findings From Classification of Sentiments in Posts

Table 2 presents the frequency distribution of sentiment analysis, with examples for each lifestyle behavior provided in Multimedia Appendix 4.

The overall percentage of positive sentiments almost doubled that of negative sentiments (1874/3320, 56.5%) vs (1027/3320, 30.9%). Results have shown a significant association between sentiment class and lifestyle behaviors (χ^2_6=67.64; P<.001), with positive sentiments being higher than negative sentiments for all lifestyle behaviors. The trends for dietary- and activity-related posts were similar, with both showing approximate percentages of 60% for positive sentiments and 27% for negative sentiments. This was followed by alcohol-related posts with positive sentiments of 54.7% (153/280). Less than half of tobacco-related posts (314/700, 44.9%) had positive sentiments, with the percentage differences between sentiment classes slightly below 2%.

[b]Not applicable.

Findings From Manual Content Analysis of Posts

A total of 1328 posts with an equal number of positive and negative sentiments for each lifestyle behavior were selected for manual content analysis. They comprised of 280 tobacco-related posts (140 posts for each sentiment class), 112 alcohol-related posts (56 posts for each sentiment class), 612 dietary-related posts (306 posts for each sentiment class), and 324 activity-related posts (162 posts for each sentiment class).

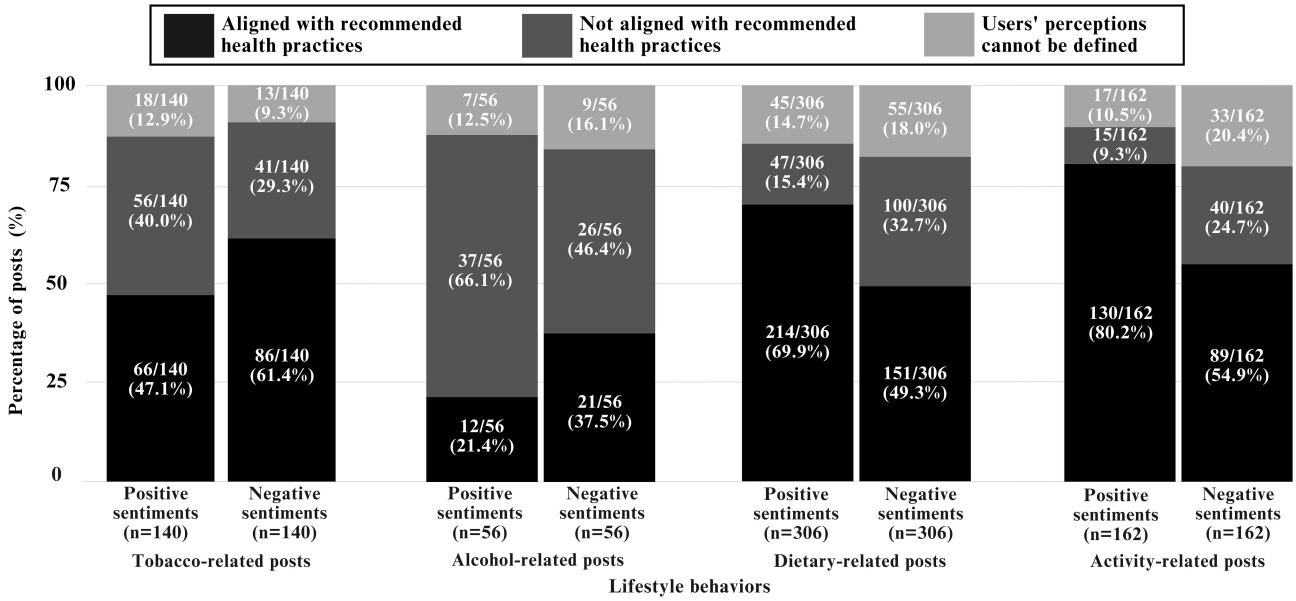
Prior to the manual content analysis of all 1328 posts, 100 posts were first subjected to interrater reliability testing. The Cohen kappa scores for both categories of post content and the alignment of users' perceptions with recommended health practices were 0.807 and 0.801, respectively.

The frequency of posts is tabulated in Table 3. Overall, the content with the 3 highest number of posts were self-narratives of current lifestyle behaviors (492/1328, 37%), general statements (203/1328, 15.3%) and planned actions (196/1328, 14.8%). Self-narratives were the most popular content for all types of lifestyle behaviors except for tobacco-related posts, in which the majority were narratives of others' current behaviors (96/280, 34.3%). Question-based posts were the least popular content for tobacco-, alcohol-, and activity-related posts, with less than 10% present in all types. Users' perceptions in more than half of the posts were aligned with recommended health practices (769/1328, 57.9%). Similar proportions were observed for all types of lifestyle behaviors except for alcohol-related posts, in which posts not aligned with recommended health practices were double those aligned with recommended health practices (63/112, 56.3% vs 33/112, 29.4%).

Figure 3 shows the frequency of posts that demonstrated the alignment of users' perceptions with recommended health practices according to the sentiment classification. A total of 3 main findings were observed. First, in dietary- and activity-related posts, significant associations between sentiment class and alignment of users' perceptions with recommended health practices were observed (χ^2_2=30.98, *P*<.001 and χ^2_2=24.16, *P*<.001; respectively). In both positive and negative sentiment classes, the percentages of posts aligned with recommended health practices were significantly higher than those not aligned with recommended health practices and those with undefined user perceptions, with percentages ranging from 49.3% to 80.2%. Posts with positive sentiments that aligned with recommended healthy practices showcased users' optimism to stay healthy (eg, "I'm ready to cut sugar. Let's go" [D-919-positive]). Meanwhile, negative sentiments that aligned with recommended healthy practices highlighted users' worries to stay healthy (eg, "Feel the weight.. rise suddenly. Sad. Have to fix it" [P-522-negative]).

Second, in tobacco-related posts, there was no significant association between sentiment class and alignment of users' perceptions with recommended health practices (χ^2_2=5.76; *P*=.06). Among posts with positive sentiments, the percentage of posts that aligned with recommended health practices was similar to those not aligned with recommended health practices, with a percentage difference of 7.1%. When users posted about tobacco with positive emotions, the likelihood of their perceptions aligning with the recommended health practices of not smoking (eg, "Please pray that I can stop smoking…" [T-563-positive]) or aligning with hazardous smoking practices (eg, "My kind of chill with cigar" [T-412-positive]) were similar. Despite the lack of significant association, the percentage of posts with negative sentiments that aligned with recommended health practices was noticeably higher than those that did not align with recommended health practices (86/140, 61.4% vs 41/140, 29.3%).

Third, a lack of significant association between sentiment class and alignment of users' perceptions with recommended health practices was also observed in alcohol-related posts (χ^2_2=4.62; *P*=.10). Although the findings were not statistically significant, the percentage of posts not aligned with recommended health practices was higher than those aligned with recommended health practices for both positive (37/56, 66.1% vs 12/56, 21.4%) and negative (26/56, 46.4% vs 21/56, 37.5%) sentiment classes.



XSL•FO
RenderX

Positive sentiments leading to alcohol consumption included celebratory posts (eg, "I'm gonna have so much wine this weekend" [A-55-positive]), whereas negative sentiments involved users coping with worries ("I am going to drown my sorrows in alcohol and pick things back up tomorrow" [A-198-negative]). Examples of posts selected for manual content analysis are provided in Multimedia Appendix 5.

Table . Frequency of posts according to post content and alignment of users' perceptions with recommended health practices (n=1328).

Category	Lifestyle behaviors				Total posts (N=1328)
	Tobacco-related (n=280)	Alcohol-related (n=112)	Dietary-related (n=612)	Activity-related (n=324)	
Post content, n (%)					
Self-narrative of current lifestyle behaviors	70 (25)	36 (32.1)	243 (39.7)	143 (44.1)	492 (37)
Narrative of others' current lifestyle	96 (34.3)	17 (15.2)	40 (6.5)	22 (6.8)	175 (13.2)
Planned action related to lifestyle behaviors	26 (9.3)	15 (13.4)	97 (15.8)	58 (17.9)	196 (14.8)
Recommendations related to lifestyle behaviors	35 (12.5)	13 (11.6)	83 (13.6)	46 (14.2)	177 (13.3)
Direct question	17 (6.1)	6 (5.4)	45 (7.4)	17 (5.3)	85 (6.4)
General statement	36 (12.8)	25 (22.3)	104 (17)	38 (11.7)	203 (15.3)
Alignment of users' perceptions with recommended health practices, n (%)					
Aligned with recommended health practices	152 (54.3)	33 (29.4)	365 (59.7)	219 (67.6)	769 (57.9)
Not aligned with recommended health practices	97 (34.6)	63 (56.3)	147 (24)	55 (17)	362 (27.3)
Users' perceptions cannot be defined	31 (11.1)	16 (14.3)	100 (16.3)	50 (15.4)	197 (14.8)

Figure 3. Stacked bar charts of alignment of users' perceptions with recommended health practices stratified according to sentiment classification. A Pearson chi-square test was conducted for each lifestyle behavior to test the associations between sentiment class and alignment of users' perceptions with recommended health practices (tobacco: χ^2_2=5.76, *P*=.06; alcohol: χ^2_2=4.62, *P*=.10; dietary: χ^2_2=30.98, *P*<.001; activity: χ^2_2=24.16, *P*<.001).

Discussion

Overview

To the best of our knowledge, this is the first study in the region that examined discussions on X across multiple lifestyle behaviors. This study is also the first of its kind that used dual approaches of lexicon-based sentiment analysis and manual content analysis of posts to examine users' sentiments, post content and the alignment of users' perceptions with recommended health practices. Positive sentiments were significantly higher than negative sentiments for all 4 lifestyle behaviors. In dietary- and activity-related posts, users exhibited twice as many positive sentiments as negative ones. The majority of the sampled posts were self-narratives of current lifestyle behaviors. More than half of the sampled tobacco-, dietary-, and activity-related posts were aligned with WHO's recommended health practices, with contrasting results in alcohol-related posts.

Principal Findings

Data scraping has shown that dietary-related topics were the lifestyle behaviors most frequently discussed. The usage of a more extensive set of search terms in scraping dietary-related posts covered a variety of nutrition-based topics involving individuals across all age groups. This resulted in dietary-related discourses among young children and adolescents (eg, formula milk, vegetables, and fruits consumption). Users frequently mentioned "rice," which is attributed to Malaysians' staple diet, with the average Malaysian adult consuming 82.3 kilograms of rice annually [33]. In contrast, alcohol-related topics were the least discussed lifestyle behaviors among users. Alcohol-related discussions in Malaysia were largely anchored on themes related to cultural and religious beliefs. Alcohol consumption among Malaysians is generally lower as behaviors are influenced by compartmentalization among the three main races in Malaysia [34]. Malays who are Muslims are not allowed to consume alcohol as it is forbidden in Islam [35], whereas no restrictions were imposed on the Chinese and Indian communities [34]. The prohibition of alcohol consumption in certain communities was hypothesized as one of the reasons for the lower frequency of alcohol-related posts, compared to other lifestyle behaviors.

Findings indicate that positive sentiments significantly outweighed negative sentiments for all lifestyle behaviors. In dietary- and activity-related posts, positive sentiments were found to be twice as many as negative sentiments, which is consistent with the sentiment analysis findings of Shaw et al [36] who analyzed over 1.5 million posts on dietary and exercise topics. In our study, more than half of the sampled posts were either self-narratives or planned actions for self-implementation. It could be postulated that the posts with positive sentiments were driven by self-determination theory (SDT), a comprehensive theory of human motivation and personality that focuses on individuals' intrinsic tendencies for growth. SDT assumes the importance of autonomous motivation, which is a type of self-emanating motivation that is consistent with users' innate values to engage in behaviors or pursue a goal [37,38]. The field of autonomous motivation has been extensively studied in the context of dietary and exercise lifestyle behaviors [39-41]. Individuals who are autonomously motivated have a sense of self-control over their actions (eg, choose to exercise regularly), leading to an increase in positive sentiments, personal fulfilment and enjoyment in the actions pursued [40].

In tobacco-related posts, positive sentiments were found to be higher than negative sentiments, albeit with a small percentage difference. This suggests that in tobacco-related discourses, users tend to either feel positive emotions (eg, satisfaction, happiness, and trust) or negative emotions (eg, dissatisfaction, unhappiness, and worry). Mixed sentiments were found to be prevalent in discussions related to vaping among both the scientific community [42], and the general public [43]. In Malaysia, the Health Ministry has proposed the Generational End Game plan, which would ban tobacco sales for those born after 2005. The bill was first tabled at the country's parliamentary discussions in July 2022 and has yet to be finalized at the time when the social media posts were scraped from X [44]. Such uncertainties towards health policy changes have generated both positive and negative reactions, with the issue being debated constantly throughout the year. Users either praised the government's efforts to mitigate smoking behaviors or expressed concerns about such "untested" plans [45]. The negative reactions may also stemmed from users' awareness of the adverse effects of smoking, with over 90% of male lung cancer patients in Malaysia having a significant history of smoking [46]. In addition, 3500 out of 10,000 annual deaths were linked to smoking [47].

As discussed, the predominance of self-narratives in posts related to diet, physical activity and alcohol consumption is likely due to users' autonomous motivation and self-awareness to perform a behavior. Conversely, most posts related to tobacco were found to be linked to narratives of other users. As tobacco smoking has been associated with social stigmatization due to its negative health impact on others, users may have been more reluctant to post from a first-person perspective. Instead, users opt to openly discuss the smoking habits of others. In addition, sharing experiences in a third-person perspective may be preferred by users to maintain anonymity. During the 20th century, smokers were often viewed as "mysterious" or "cool," but this social status has slowly diminished over the past two decades [48,49]. In Malaysia, this was propelled by smoking reduction strategies, such as the ban on smoking in public eateries implemented in 2019, that socially impacted users' impression toward smoking [50].

In recent years, there has been a growing trend of health influencers using online platforms to actively share their dietary and fitness regimens. Previous studies have shown that social media users who were exposed to this information delivered by health influencers as well as content from other social media users, were more likely to be receptive to adopting healthy practices, such as maintaining a balanced diet and being physically active [51-53]. The results were consistent with the findings of this study, which showed a significantly higher percentage of dietary- and activity-related posts by social media users that were aligned with recommended health practices. Nevertheless, HCPs must remain active in advocating positive lifestyle behaviors on social media. Although almost one-fifth of posts for these two lifestyle behaviors were on planned

XSL•FO
RenderX

actions, this may not always translate into actions by the population. This is a caveat of much research that relies on social media or self-reported data on social media. It is often unclear whether individuals actually follow through on what they post about, highlighting the intention-behavior gap [54]. Findings from the Malaysian National Health and Morbidity Survey (NHMS) survey conducted in 2023 have shown that the actual adoption of healthy practices was still lacking among the Malaysian public. Almost 95.1% Malaysian adults did not meet the recommended daily intake of fruits and vegetables, consuming only two servings of fruit or vegetables daily instead of the recommended five servings daily [3] The prevalence of physical inactivity among Malaysian adults was at 29.9% [3], which was also considerably higher than other Asian countries, including China and India [55,56].

There was a lack of significant association between sentiment class and alignment with recommended health practices in both tobacco- and alcohol-related posts. Despite the smaller number of sampled alcohol-related posts, it is interesting to note that users' perceptions with recommended health practices had contrasting outcomes compared to the other three lifestyle behaviors. In more than half of the alcohol-related posts with positive and negative sentiments, users' perceptions were not aligned with recommended health practices. Most users perceived alcohol consumption as a casual and an affordable social activity and did not acknowledge the potential health risks involved. A survey conducted in Thailand, a country of similar income setting, had previously mentioned the popularity of alcohol being a social activity among urban communities [57]. In Malaysia, alcoholic beverages were available for purchase at neighborhood convenience stores, which allowed for easy purchases of takeaway alcohol [35]. This further downplayed users' awareness of the negative consequences of alcohol consumption [58].

Assessment of posts made by social media users on X allows HCPs to identify priority areas for social media-based health information delivery on this platform. As most alcohol-related posts do not align with health recommendations, it is postulated that greater emphasis should be placed on strategies to limit alcohol consumption among users in Malaysia. The WHO has proposed collaborative efforts with HCPs and journalists to improve targeted public health messaging to the public. A guide was recently developed for journalists to facilitate media reporting to communities on the harms of alcohol consumption [58]. While the other 3 lifestyle behaviors were mostly aligned with recommended health practices, it remains essential for HCPs to continuously deliver information advocating healthy behaviors. Online approaches allow HCPs to deliver information beyond geographic barriers, reaching a wider audience in diverse community settings. Therefore, health information can be adopted by users in countries with similar cultural beliefs, including countries within the Southeast Asia region.

Strengths and Limitations

The strengths of this study included its comprehensive coverage of 4 lifestyle behaviors aimed at reducing the 4 key modifiable risk factors under WHO's health priority [4]. This allowed for the simultaneous analysis of posts across different lifestyle behaviors. Unlike most studies that focus on global contexts, this research uniquely focused on the Malaysian context. It provides insights into the cultural and social dynamics that influence discussions around lifestyle behaviors in this specific region. Notably, the inclusion of alcohol-related posts in analysis shed light on culturally and socially nuanced discussions within the region. This is particularly valuable in regions like Malaysia, where religious and cultural factors strongly influence alcohol consumption. In addition, the retrospective examination of social media posts utilized approaches of lexicon-based sentiment analysis and manual content analysis. The dual approach provided real-time and spontaneous insights into users' opinions on lifestyle behaviors while addressing limitations of single-method studies. Findings from this study could assist HCPs in prioritizing the delivery of region-specific health information through social media.

Nevertheless, a few limitations should be considered. First, potential bias may exist during the selection of social media dataset. In self-selection bias, users who choose to share their opinions on social media may not represent the broader population. The study may be subjected to data selection bias as it included only social media posts in Malay and English, excluding other spoken languages in Malaysia, such as Chinese and Tamil. Nevertheless, sentiment analysis studies on X in Malaysia have largely concentrated on data scraped in Malay and English [59,60]. Demographic bias may be present due to the overrepresentation or underrepresentation of certain groups on X. For instance, the majority of users in Malaysia who post on social media are aged between 25 and 34 years old [9]. The limitations in the availability of metadata on X also prevented the collection of demographic data such as age, gender and race, as most users did not disclose this information in their profiles. Population bias may occur in geotagged posts utilizing longitude and latitude metadata. Previously literature has indicated that only 1% of users would geotag their location in posts [61]. Nevertheless, this is the most effective method to scrape posts that are published within a specific location.

Second, there are limitations in the study design and methods used for sentiment analysis and manual content analysis. The study is cross-sectional in nature and provides a snapshot of discussions at a specific time. Therefore, temporal bias may exist, making it challenging to track changes in sentiments or behaviors over time. In addition, posts that were collected for sentiment analysis and manual content analysis over two consecutive months may not accurately reflect year-round sentiments and discussions, as findings may vary due to the presence of health-related events occurring at certain times of the year. The events may include a change in legislations, prominent public health campaigns or disease outbreaks. The quality of the dataset was ensured by verifying that there were no notable health-related occurrences between November and December 2022. In addition, previous studies analyzing users' sentiments and content have similarly explored health data over two consecutive months [23,24]. The manual content analysis of social media posts can be time-consuming due to the involvement of large datasets, therefore, only 20% of the total posts were randomly selected using stratified sampling. This percentage was previously utilized in a content analysis study

XSL•FO
RenderX

by Mathieson et al [30]. While analyzing the full dataset would provide more comprehensive findings, the randomized sample offers a reliable snapshot for identifying the thematic content without the substantial time and resource demands of manual analysis for the entire dataset. Furthermore, prior to sentiment analysis, the computer-assisted translation of posts from Malay to English may have led to inaccuracies due to the usage of local dialects, sarcasm or slangs. To enhance sentiment labeling, the structures of translated posts with neutral sentiments that were unclear were manually refined, and sentiment analysis was repeated.

Third, the study results should be interpreted with caution, regarding posts on alcohol consumption due to the smaller sample size of 112 posts. A power analysis indicated that this sample size is adequate for detecting effects, with a power of 0.82. Furthermore, we acknowledge the presence of potential interactions in posts with overlapping lifestyle behaviors (eg, a post that talks about diet and physical activity). In sentiment analysis, the conduct of Pearson chi-square tests also did not account for potential confounding factors or interactions in posts with overlapping lifestyle behaviors. To account for this limitation, we compared the proportions between sentiment count for posts showing 1 lifestyle behavior only (n=3180), and sentiment count for posts across 4 types of lifestyle behaviors (n=3320). The proportions of sentiment counts for both were similar to each other. In addition, while many of the Pearson chi-square associations were significant, these may not imply causality and thus may not inform categorically that the observed sentiments result in practicing different lifestyle behaviors or the direction of the relationship.

Implications and Further Research

The findings from this study could help HCPs to prioritize the delivery of health information on lifestyle behaviors using social media tailored to the targeted region, which is Malaysia. Given the low number of alcohol-related posts by social media users in Malaysia, HCPs could focus on initiating positive discussions around this topic to raise awareness about the harmful effects of alcohol consumption. In addition, most of the alcohol-related posts made by social media users were not aligned with recommended health practices. There is an increased need for HCPs to emphasize on limiting and stopping alcohol consumption, while also acknowledging that the users' attitudes towards alcohol consumption may still vary among different religions in Malaysia. Health advocacy for positive lifestyle behaviors on social media should continue for the other three lifestyle behaviors.

Further research could be proposed to explore the opinions of social media users toward lifestyle behaviors in Malaysia. First, despite the statistical significance observed in the associations between sentiment classification and lifestyle behaviors, the percentage difference between both sentiment classes in tobacco-related posts was small. Therefore, it would be interesting to investigate whether tobacco sentiments would vary over time. We may want to further track sentiments by time series analysis to explore changes in users' emotions towards tobacco across a time period. The tracking of real-time sentiments across a time period was previously conducted in a review examining public health data on X that included posts on alcohol consumption [62]. In addition, since posts are scraped based on location metadata, future studies could leverage on this data to explore the relationship between the prevalence of specific lifestyle behaviors in certain locations (eg, urban areas in Malaysia) and the intensity of lifestyle behavior-related discussions on social media. A similar study has previously been conducted in the United States; therefore, conducting such studies in the Malaysian context would be beneficial [63].

Second, the majority of posts involved content related to self-narratives of lifestyle behaviors. These self-narratives outlined X's roles as a microblog for users to freely express the behaviors they practice from a first-person perspective. As self-narratives encompass a broad and generalized category, it may be beneficial to conduct a more detailed examination of posts that only described users' self-narratives. This in-depth analysis would provide insights into the specific themes commonly discussed by users from a first-person perspective. In addition, the examination of posts could be extended to other lifestyle behaviors such as sleep patterns, which is particularly relevant as active social media users are mainly adolescents and young adults who are commonly affected by sleep-related issues [64].

Third, this study was conducted on the microblogging platform X. It is also important to examine social media posts made by users on other platforms, such as Facebook. Future research is proposed to analyze the sentiments and content of posts on these platforms. Audience demographics can vary across these platforms. For instance, younger millennials may be more active on X, whereas Facebook often attracts a slightly older audience [65,66]. Comparing our study findings with those obtained from Facebook could help HCPs to deliver health messages that suit the audiences of different social media platforms.

Fourth, our study emphasizes accessibility and simplicity in data visualization and reporting to effectively communicate findings to a diverse audience, including non-technical stakeholders such as HCPs, public health practitioners and policymakers. To achieve this, we employed techniques like word clouds, which provide a visually appealing representation of frequently mentioned terms in the dataset, and lexicon-based sentiment analysis, which is straightforward to implement as it does not require additional labeled data or extensive training. We recognize the potential value of more advanced methods and suggest exploring these techniques in future studies related to the conduct of in-depth text analysis. These may include approaches like topic modeling or keyword co-occurrence analysis to summarize text data through word groups, as well as training machine learning models such as support vector machines or Naïve Bayes to classify sentiments. Furthermore, hybrid methods of sentiment analysis could be explored by integrating machine learning models with lexicon-based approaches. These combined models can then be assessed for accuracy and robustness through comparative analysis. Similar studies have been conducted previously in both health and non-health posts [67,68].

XSL•FO
RenderX

Conclusion

In conclusion, the incorporation of lexicon-based sentiment analysis holds significance as it enabled the use of large amounts of data to capture users' emotions whilst posting on lifestyle behaviors. Positive sentiments were significantly expressed in posts for all lifestyle behaviors. Nevertheless, there was a small percentage difference observed in tobacco-related posts, indicating a more varied sentiment among users. Most of the posts showed users' own narratives and planned actions towards the conduct of a behavior. As the majority of alcohol-related discussions were not aligned with recommended health practices, this reflects the need for individual HCPs and health organizations to increase their delivery of health information pertaining to alcohol consumption on social media platforms. It is also equally important for HCPs to continue providing health information on other lifestyle behaviors to social media users, while monitoring ongoing discussions by users on social media.

Abstract

Background: There is breast cancer–related medical information on social media, but there is no established method for objectively evaluating the quality of this information. Principles for Health-Related Information on Social Media (PRHISM) is a newly developed tool for objectively assessing the quality of health-related information on social media; however, there have been no reports evaluating its reliability and validity.

Objective: The purpose of this study was to statistically examine the reliability and validity of PRHISM using videos about breast cancer treatment on YouTube (Google).

Methods: In total, 60 YouTube videos were selected on January 5, 2024, with the Japanese words for “breast cancer,” “treatment,” and “chemotherapy,” and assessed by 6 Japanese physicians with expertise in breast cancer. These evaluators independently evaluated the videos using PRHISM and an established tool for assessing the quality of health-related information, DISCERN, as well as through subjective assessments. We calculated interrater and intrarater agreement among evaluators with CIs, measuring agreement using weighted Cohen kappa.

Results: The interrater agreement for PRHISM overall quality was κ=0.52 (90% CI 0.49-0.55), indicating that the expected level of agreement, statistically defined by the lower limit of the 90% CI exceeding 0.53, was not achieved. However, PRHISM demonstrated higher agreement compared with DISCERN overall quality, which had a κ=0.45 (90% CI 0.41-0.48). In terms of validity, the intrarater agreement between PRHISM and subjective assessments by breast experts was κ=0.37 (95% CI 0.14-0.60), while DISCERN showed an agreement of κ=0.27 (95% CI 0.07-0.48), indicating fair agreement and no significant difference in validity.

Conclusions: PRHISM has demonstrated sufficient reliability and validity for evaluating the quality of health-related information on YouTube, making it a promising new metric. To further enhance objectivity, it is necessary to explore the use of artificial intelligence and other approaches.

Introduction

In recent years, advances in medical technology and diagnostic methods have made health care increasingly complex, leading to a growing tendency for patients to seek information about their disease and treatments [1]. Many patients feel anxious during this process, and internet use for collecting medical information is increasing [2]. In Japan, about 50% of people use the internet as a method for collecting medical information [3]. The sources of information include those officially provided by national cancer centers, as well as those from social media. On social media, anyone can post information regardless of their expertise or qualifications, making it very difficult for patients to judge the quality of that information, which is often a mix of reliable and unreliable sources [4]. The spread of misinformation about vaccines during the COVID-19 pandemic highlighted the problem of inaccurate medical information on social media [5,6]. In response to this issue, the National Academy of Medicine (NAM) published a guide in 2021 to help identify reliable sources of health information on social media [4].

Methods for objectively evaluating the quality of medical information available on the internet have included Diagnostic Information Support Communication Evaluation Report Network (DISCERN) [7]. DISCERN was developed as a tool to assess the quality of written information about treatment choices. It is a metric that evaluates the quality of information using 16 questions, consisting of 15 basic assessments and 1 overall assessment, each scored on a 1 (No) to 5 (Yes) Likert scale. This metric has long been considered reliable and is currently used to assess the quality of breast cancer treatment information available on the internet [8,9]. However, since they were developed before the year 2000 and were not designed with social media in mind, there are concerns that they may be inadequate for evaluating social media [10].

Given the increasing reliance on the internet for health information, it is crucial to ensure that the information available to patients is accurate and reliable. Misinformation can lead to incorrect self-diagnosis, inappropriate treatment choices, and increased anxiety, ultimately affecting patient outcomes and public health. Therefore, there is a pressing need to develop and validate tools specifically designed to evaluate the quality of medical information on social media platforms.

Denniss and colleagues [10] developed the Principles for Health-Related Information on Social Media (PRHISM) tool to evaluate health-related information on social media using a modified Delphi method. This tool assesses 13 principles on a 0 (completely unmet)-4 (completely met) Likert scale and allows nonexperts to evaluate the quality of information, potentially reducing reviewer bias. Compared with existing metrics for evaluating information, PRHISM was specifically designed for social media, offering greater logical validity. Its questions are tailored for social media platforms, with additional considerations for readability and accommodations for vision and hearing impairments. Although PRHISM has not yet been widely used for social media evaluation, its development through appropriate methods and its adaptability suggest it could be valuable for this purpose.

To address these challenges, we adapted a Japanese version of PRHISM and evaluated its reliability and validity. We also conducted assessments using DISCERN, widely used for evaluating medical information quality, and compared the results with PRHISM. Our goal was to evaluate whether PRHISM could adequately assess information quality on Japanese social media and, using this tool, create an environment where patients can access accurate medical information.

Methods

Translation of the PRHISM

To use PRHISM in Japan, we obtained permission from the developers of PRHISM. First, PRHISM was translated from English to Japanese by a native Japanese speaker (H Kusama). Then, the Japanese version was back-translated into English by a native English speaker. Any discrepancies between the back-translated English version and the original text were identified, and the Japanese version appropriately adjusted (Multimedia Appendix 1).

Social Media Platform

The evaluation of PRHISM was conducted using YouTube (Google). YouTube is the second most used platform in Japan after LINE (LY Corporation) and is used across all age groups [11]. Among various platforms, we determined that YouTube is suitable for this evaluation because it allows the posting of longer videos, enabling experts to adequately assess the medical information provided.

How to Search

Since YouTube uses an algorithm that analyzes viewing history through artificial intelligence (AI) to prioritize related videos, searches were conducted using the internet browser Google Chrome in incognito mode, with no login session active. The search terms used were the Japanese words “乳癌” (にゅうがん, Nyugan, breast cancer), “治療” (ちりょう, Tiryou, treatment), and “抗癌剤” (こうがんざい, Kouganzai, chemotherapy). The search was conducted on January 5, 2024, and the results were sorted by relevance, with the videos listed in order from the top. The exclusion criteria were (1) languages other than Japanese, (2) fewer than 3000 views, (3) shorter than 60 seconds, (4) irrelevant videos, (5) without audio, (6) YouTube shorts, (7) duplicates, and (8) advertisements.

The sources of the videos were categorized into eight categories: (1) health profession schools and other educational institutions (schools of medicine, pharmacy, etc); (2) health care facilities (hospitals, clinics, etc); (3) nonprofit health plans; (4) public health departments (national statement, regional statement, etc); (5) individual health care professionals (doctors, nurses, occupational therapists, etc); (6) entertainment, media, news; (7) personal blogs; and (8) other.

These categories were created with reference to the reliable sources identified by the National Academy of Medicine [4]. Categories 1 - 4 were defined as content from reliable sources, while categories 5 - 8 were defined as content from other

XSL•FO
RenderX

sources. In addition, general information, such as the uploader, number of channel subscribers, number of views, video length, upload date, number of likes, and time since posting, was also collected.

Evaluators

In total, 6 physicians with expertise in breast cancer conducted the evaluations. All of them were surgical oncologists, and the authors recruited participants from their own institution and affiliated hospitals for this study. : KA (8 y as a physician, 1 y as a breast expert), YI (9 y as a physician, 2 y as a breast expert), RS (10 y as a physician, 2 y as a breast expert), HS (16 y as a physician, 7 y as a breast expert), YH (24 y as a physician, 15 y as a breast expert), and H Kaise (37 y as a physician, 20 y as a breast expert).

Evaluation Method

In total, 6 physicians with expertise in breast cancer evaluated a common set of 60 videos. For each video, they used PRHISM and DISCERN for evaluation. In addition, the accuracy and potential harm of the information was assessed.

PRHISM

PRHISM evaluates the quality of health-related information on social media using 13 principles, which are scored on a 0 - 4 Likert scale [9].

Since some items may not be applicable depending on the content of the video, the score is calculated based on the applicable questions and converted to a score out of 100 (PRHISM score). Scores of 100 - 76 are rated as excellent, 75 - 51 as good, 50 - 26 as mediocre, and 25 - 0 as poor (Textbox 1).

XSL•FO
RenderX

Textbox 1. Summary of the evaluation tools used in this study.

Principles for Health-Related Information on Social Media (PRHISM)

PRHISM is comprised of 13 principles. Each principle is scored on a 5-point Likert scale (0-4).

Principles:

1. Authorship
2. Authoritative
3. Action-oriented
4. Financial disclosure
5. Attribution
6. Balance and justifiability
7. Risks and benefits
8. Privacy
9. Complementary information
10. Referrals and support
11. Readability and comprehensibility
12. Accessibility
13. Images

DISCERN

DISCERN is comprised of 8 reliability assessments, 7 information quality assessments, and one overall quality assessment. Each principle is scored on a 5-point Likert scale (1-5).

Reliability:

1. Are the aims clear?
2. Does it achieve its aims?
3. Is it relevant?
4. Is it clear what sources of information were used to compile the publication (other than the author or producer)?
5. Is it clear when the information used or reported in the publication was produced?
6. How good is the quality of information treatment choices?
7. Is it balanced and unbiased?
8. Does it provide details of additional sources of support and information?

Information quality:

1. Does it refer to areas of uncertainty?
2. Does it describe how each treatment works?
3. Does it describe the benefits of each treatment?
4. Does it describe the risks of each treatment?
5. Does it describe what would happen if no treatment is used?
6. Does it describe how the treatment choices affect overall quality of life?
7. Is it clear that there may be more than one possible treatment choice? Does it provide support for shared decision-making?

Overall evaluation:

1. Overall rating of the publications.

Cancer Expert Assessment Tool

Cancer expert assessment tool is comprised of 4 question assessments. Two assessments consist of whether the information is true or false and harmful or not harmful, and 2 review reasons why the evaluation was chosen.

Expert Panel Member Assessment:

XSL•FO
RenderX

1. In your opinion, are the primary medical claims within the article accurate?
   - 5: True, 4: Mostly true, 3: Mixture both True/False, 2: Mostly False, 1: False.
2. If you answered, "Mixture both True/False," "Mostly False" or "False," why did you answer this way?
3. In your opinion, could the primary medical claims within the article cause harm?
   - 5: Certainly NOT Harmful, 4: Probably NOT Harmful, 3: Uncertain, 2: Probably Harmful, 1: Certainly Harmful.
4. If you answered, "Uncertain" or "Probably Harmful" or "Certainly Harmful," why did you answer this way?

DISCERN

DISCERN evaluates the scientific reliability of medical information related to treatment descriptions and assigns a score [8]. The total score is out of 80 points, with each of the 16 assessments contributing up to 5 points (DISCERN score) (Textbox 1).

Accuracy and Potential Harm of the Information

The subjective assessment was conducted using an assessment tool developed by Johnson et al [12]. This tool assesses whether the provided medical information is accurate or inaccurate, and if considered inaccurate, the reason is marked in a checkbox. In addition, it evaluates whether the information is harmful or not using the same tool. Accurate information is rated as 1, and inaccurate information as 5, on a Likert scale. Similarly, nonharmful information is rated as 1, and harmful information as 5. To align the scoring methods of PRHISM and DISCERN, in this study, accurate or nonharmful information was rated as 5, and inaccurate or harmful information was rated as 1 (Textbox 1).

Training and Protocol for Evaluators

Each evaluator received a lecture once on how to use the metrics during a preliminary meeting. The principal investigator, who is also the first author of the study, conducted the lecture in an internet-based group session in a group session for approximately 60 minutes. Subsequently, evaluation sheets, along with Japanese translations of the PRHISM and DISCERN guides [10,13], were provided. The evaluators conducted their assessments based on these guides. No further training were conducted thereafter.

Discussion among evaluators regarding each evaluation was not permitted.

Reliability

Reliability was assessed by examining the agreement of scores between evaluators. In the previous literature on DISCERN, evaluations were based on the agreement of the overall quality score. However, PRHISM does not have a corresponding criterion. For the purpose of statistical evaluation and comparison in this study, we added a "PRHISM overall quality" component, similar to that in DISCERN, which assessed the entire video after evaluating the 13 principles. This component was also scored on a 0 - 4 Likert scale, and its agreement was evaluated.

Validity

There is no gold standard for evaluating the validity of the quality of medical information. For validity, the subjective assessment of the quality of medical information by physicians with expertise in breast cancer was considered an appropriate assessment, and this was used as the standard for validity. Validity was assessed by examining the agreement between the PRHISM overall quality and the experts' subjective assessments. The validity of DISCERN was also examined in the same way.

Sample Size Determination

The number of videos to be evaluated was determined based on the interrater agreement for PRHISM overall quality. As there are no reports examining the level of interrater agreement for PRHISM, DISCERN was used as a reference. Currently, DISCERN is the primary tool used to evaluate the quality of medical information on social media. DISCERN assesses 15 criteria and then evaluates the overall quality of the information. In previous studies, the agreement on the overall quality has been evaluated. Cohen kappa was used to evaluate the degree of agreement. The degree of agreement varies depending on the expertise of the evaluators, with a kappa of 0.23 reported for self-help group members, 0.40 for information providers, and 0.53 for an expert [7].

The expected agreement for PRHISM overall quality was assumed to have a threshold of κ=0.53 and an expected value of κ=0.61. The threshold of 0.53 was determined based on the assumption that PRHISM, being a tool specifically designed for evaluating social media, would achieve a higher level of agreement than DISCERN for an expert. The expected value of 0.61 is generally considered to indicate "sufficient agreement" in terms of the kappa coefficient [14]. For the number of videos to be evaluated in this study, it was necessary to assume the distribution of the overall quality scores in PRHISM. Therefore, as a pilot test, the investigator (HK [Hiroki Kusama]) evaluated 50 videos to establish this distribution in Multimedia Appendix 2. Based on the above settings, the number of videos was determined through a simulation experiment conducted 10,000 times. Assuming an alternative hypothesis kappa coefficient of 0.61, the number of videos required to reject the null hypothesis of 0.53 with over 80% power at a 2-sided significance level of 10% was calculated to be 55 for 6 evaluators. The z test, approximated by a normal distribution, was used to calculate the test statistics [15]. Anticipating that some videos might be difficult to evaluate, we decided to have 6 evaluators assess 60 videos. The 6 evaluators were distributed, with 3 physicians having more than 10 years of experience and 3 physicians having less than 10 years of experience.

XSL•FO
RenderX

Statistical Analysis

The primary analysis focused on examining the interrater agreement for PRHISM overall quality (reliability of PRHISM) and DISCERN overall quality (reliability of DISCERN).

As secondary analyses, we examined the following:

- The intrarater agreement between PRHISM overall quality and DISCERN overall quality.
- The intrarater agreement between PRHISM overall quality and expert evaluations (validity of PRHISM).
- The intrarater agreement between DISCERN overall quality and expert evaluations (validity of DISCERN).
- The interrater agreement for PRHISM score and its categories (reliability of PRHISM).
- The interrater agreement for DISCERN score and its categories (reliability of DISCERN).

To compare the DISCERN score with the PRHISM score, we calculated the modified DISCERN score by subtracting the DISCERN overall quality score from the total DISCERN score, dividing the result by the maximum possible score based on the number of applicable questions, and then converting it to a score out of 100 (modified DISCERN score).

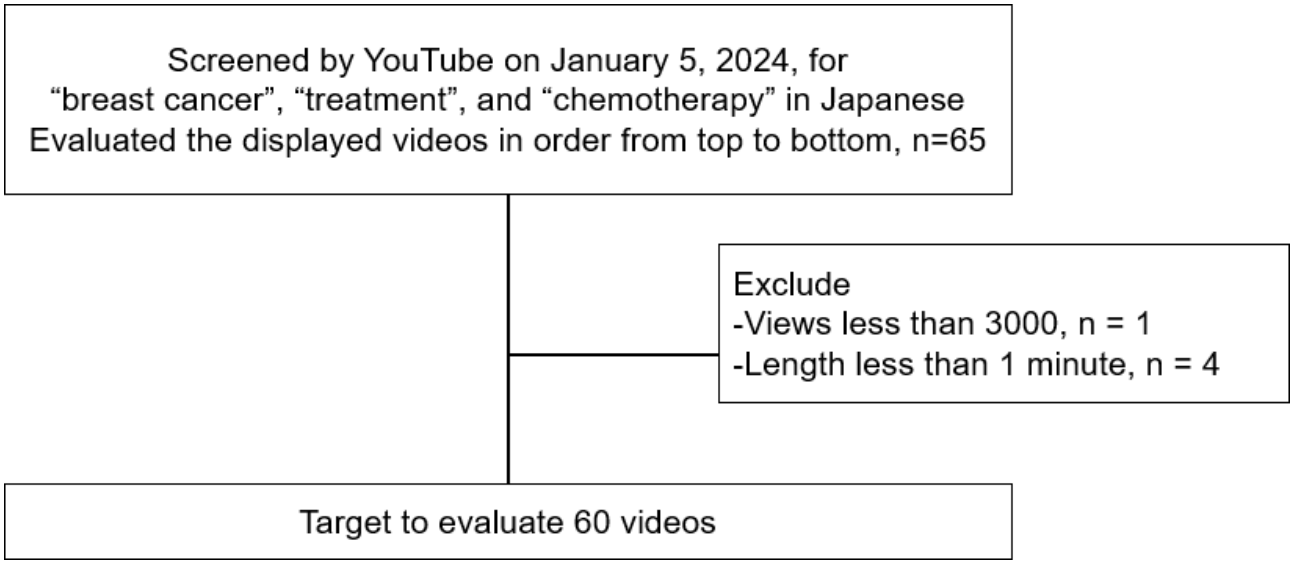
The agreement of evaluations was assessed using the kappa coefficient. The interpretation of agreement levels is as follows: <0.00 (no agreement); 0.00 - 0.20 (slight); 0.21 - 0.40 (fair); 0.41 - 0.60 (moderate); 0.61 - 0.80 (substantial); and 0.81 - 1.00 (almost perfect) [14]. The interobserver agreement was calculated using the kappa coefficient and a 90% CI, and an agreement level of 0.61 or higher was interpreted as sufficient.

For the interrater agreement of the PRHISM overall quality, 2 evaluators were selected from a group of 6, and the agreement for 15 different patterns was calculated. The average and the 90% CI were calculated [15]. The 90% CI was calculated using normal approximation. If the lower limit of the 90% CI exceeded 0.53, the primary analysis (PRHISM reliability) was considered to have been achieved.

For the secondary analyses, the kappa coefficient and its 95% CI were calculated for each pair of evaluators to assess intrarater agreement. Secondary analyses for the interrater agreement were performed using the same approach as the primary analysis.

In addition, since the PRHISM score and the modified DISCERN score are continuous variables, we also performed an analysis using intraclass correlation coefficient. Statistical analyses were performed using R software (version 4.2.3; R Core Team).

Ethical Considerations



The study was approved by the Institutional Review Board of Tokyo Medical University (T2024-0034). The study involved an analysis of publicly available YouTube data, which does not require individual consent from participants. However, ethical approval was obtained to ensure that the research adhered to institutional guidelines for research involving public data. No compensation was provided to participants as this study involved an analysis of publicly available data. Should any concerns or complaints be raised by video contributors or their families regarding ethical or social issues, the principal investigator will respond sincerely and appropriately in line with institutional procedures.

Results

Overview

Using the predefined search method, we excluded 5 videos in total (1 video with fewer than 3000 views and 4 videos with a duration of less than 1 minute), resulting in a list of 60 videos. A CONSORT (Consolidated Standards of Reporting Trials) diagram is shown in Figure 1.

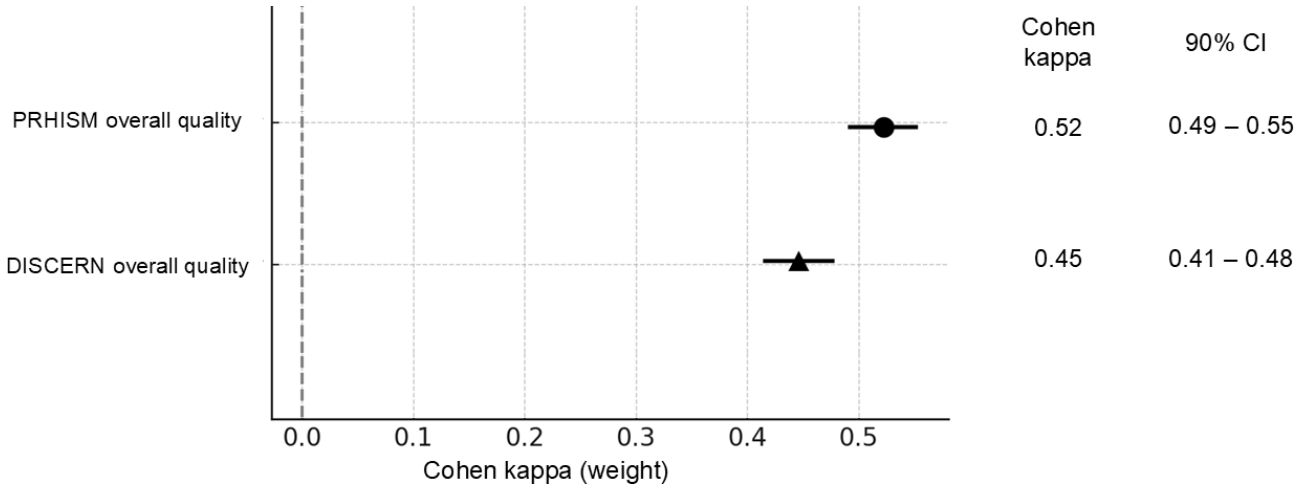
Figure 1. Flowchart of video selection in this study. In total, 60 videos were selected after excluding those with fewer views or short duration.

The median video length was 8 (range: 1 - 126) minutes, the median number of views was 30,542.5 (range: 3921 - 978,676), and the median time since posting was 29 (range: 7 - 123) months. The sources of the videos were as follows: 5 individual health care professionals accounted for the largest category with 15 videos (25%); followed by 6 entertainment, media, and news

XSL•FO
RenderX

with 13 videos (22%); 7 personal blogs with 12 videos (20%); 3 nonprofit health plans with 9 videos (15%); 1 health professions schools and other educational institutions with 6 videos (10%); 2 health care organizations with 4 videos (7%); and 8 other sources with 1 video (2%). No videos were posted from the public health departments (Table 1).

Table . The characteristics of selected videos on YouTube.



Characteristics		Statistical value (n=60)
Video length (mins), median (range)		8 (1-126)
Views, n (range)		30,542.5 (3921-978,676)
Time since posting (months), median (range)		29 (7-123)
Sources of videos, n (%)		
	Health professions schools and other educational institutions (eg, medical schools and pharmacy schools)	6 (10)
	Health care organizations (eg, academic medical centers and specialty hospitals)	4 (7)
	Nonprofit health plans	9 (15)
	Public health departments	0 (0)
	Individual health care professionals	15 (25)
	Entertainment and media news	13 (22)
	Breast cancer survivor's blog	12 (20)
	Others	1 (2)

Primary Analysis

Reliability

The interrater agreement for PRHISM overall quality was κ=0.52 (90% CI 0.49-0.55), indicating moderate agreement. Since the lower limit of the 90% CI was below 0.53, the primary analysis was not achieved. However, the interrater agreement for DISCERN overall quality was κ=0.45 (90% CI 0.41-0.48), also indicating moderate agreement. The 90% CI did not overlap, suggesting that PRHISM may be a superior measure in terms of interrater agreement compared with DISCERN (Figures 2 and 3).

Figure 2. Interrater agreement on PRHISM and DISCERN overall quality. The circle and triangle represent the mean kappa and CIs (90% CI) are represented by horizontal error bars. RenderX

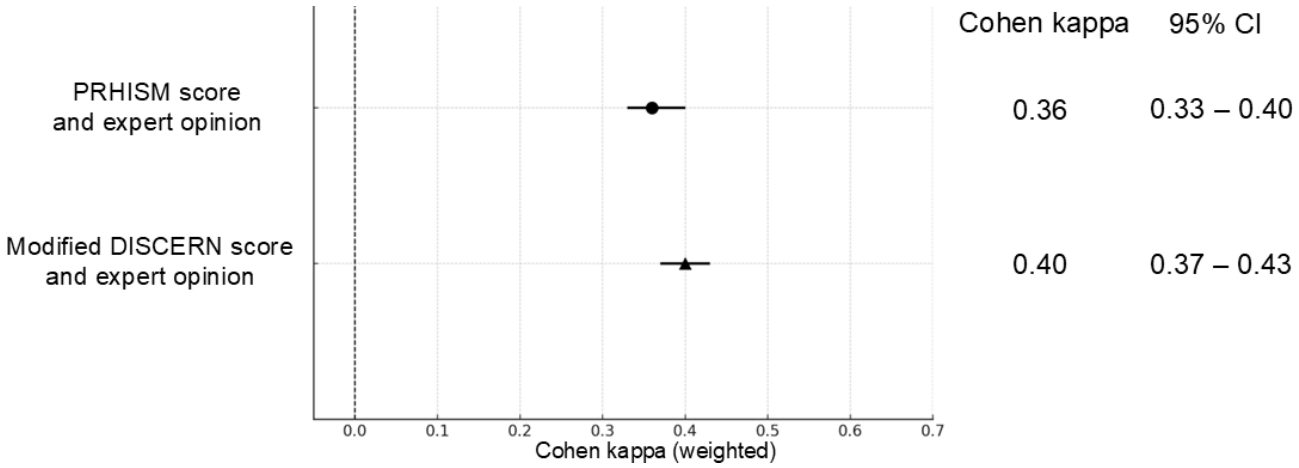
Subgroup Analysis in Primary Analysis

For videos originating from reliable sources (categories 1 - 4), the PRHISM overall quality was κ=0.45 (90% CI 0.38-0.51), and the DISCERN overall quality was κ=0.28 (90% CI 0.22-0.33). For videos from other sources (categories 5 - 8), the PRHISM overall quality was κ=0.40 (90% CI 0.36-0.44), and the DISCERN overall quality was κ=0.34 (90% CI 0.30-0.38; Figure 3, Multimedia Appendix 3). The 90% CI for PRHISM from reliable sources did not overlap with the 90% CI for DISCERN.

For those with over 10 years of experience, the PRHISM overall quality was κ=0.57 (90% CI 0.51-0.63), and the DISCERN overall quality was κ=0.60 (90% CI 0.54-0.65). For those with less than 10 years of experience, the PRHISM overall quality was κ=0.30 (90% CI 0.20-0.40), and the DISCERN overall quality was κ=0.21 (90% CI: 0.12-0.29). When the years of experience were 10 or more, the agreement on overall quality was higher for both PRHISM and DISCERN compared with those with less than 10 years of experience (Figure 3, Multimedia Appendix 4).

Secondary Analysis

Intrarater agreement for PRHISM overall quality and DISCERN overall quality was κ=0.63 (95% CI 0.55-0.73), indicating substantial agreement. In evaluating medical information on social media, there was no significant difference between the assessments of PRHISM overall quality and DISCERN overall quality (Figure 3).



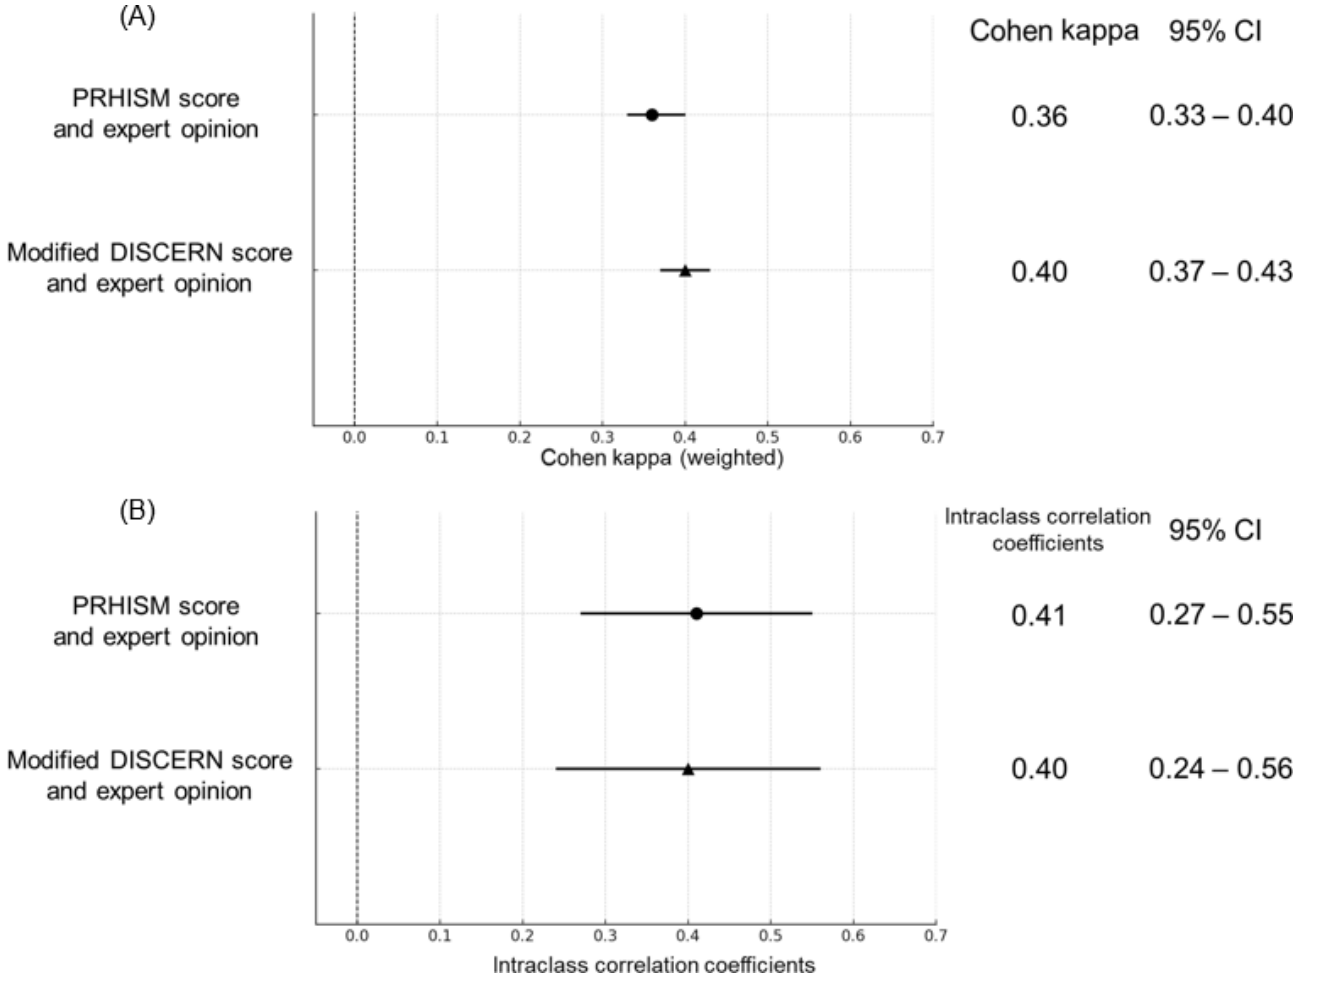
The intrarater agreement among experts was κ=0.54 (95% CI 0.50-0.57), indicating moderate agreement (Figure 3).

Validity

We evaluated the agreement between the PRHISM overall quality and DISCERN overall quality scores with the quality of information as subjectively assessed by experts. The agreement between PRHISM overall quality and the experts' subjective assessment was κ=0.37 (95% CI 0.14-0.60), indicating fair agreement. The agreement between DISCERN overall quality and the experts' subjective assessment was κ=0.27 (95% CI 0.07-0.48), indicating fair agreement. The 95% CIs overlapped, suggesting that the validity was considered equivalent (Figures 3 and 4). The 95% CIs for the agreement of each of the 6 evaluators all overlapped, but the level of agreement varied among specialists for both PRHISM and DISCERN, ranging from κ=0.07 to 0.65 and κ=0.01 to 0.51, respectively. (Multimedia Appendix 5).

The circle represents the mean kappa for PRHISM, and triangle represent the mean kappa for DISCERN. The 95% CIs are represented by horizontal error bars.

Figure 4. Intrarater agreement between PRHISM or DISCERN overall quality and expert opinion, the circle and triangle represent the mean kappa and CIs (95% CI) are represented by horizontal error bars. DISCERN: Diagnostic Information Support Communication Evaluation Report Network; PRHISM: Principles for Health-Related Information on Social Media.



Agreement Between PRHISM Score and DISCERN Score

We evaluated the interrater agreement among 6 evaluators for the PRHISM score and the modified DISCERN score, both rated on a score out of 100. The interrater agreement for the PRHISM score and the modified DISCERN score was κ=0.36 (95% CI 0.33-0.40) and κ=0.40 (95% CI 0.37-0.43), respectively (Figure 5A). Using the intraclass correlation coefficient, the PRHISM score was 0.41 (95% CI 0.27-0.55) and the DISCERN score was 0.40 (95% CI 0.24-0.56) (Figure 5B).

The circle represents the mean kappa for PRHISM, and the triangle represent the mean kappa for DISCERN. The 95% CIs are represented by horizontal error bars.

XSL•FO
RenderX

Figure 5. Intra-rater agreement between PRHISM score and modified DISCERN score and expert opinion. The circle and triangle represents the mean kappa and 95% CIs are represented by horizontal error bars. (**A**) Cohen kappa. (**B**) Intraclass correlation coefficient. DISCERN: Diagnostic Information Support Communication Evaluation Report Network; PRHISM: Principles for Health-Related Information on Social Media.

Agreement for Each Evaluation Question of PRHISM and DISCERN

For PRHISM, when a question was judged as "not applicable," it was excluded from the score calculation. Therefore, some were assessed using unweighted Cohen kappa. The highest agreement was for question 2, "authoritative," with κ=0.73 (95% CI 0.70-0.76). For DISCERN, the highest agreement was for item 12, "benefits of treatment," with κ=0.60 (95% CI 0.56-0.63) (Figure 3).

In addition, PRHISM is a metric that classifies video quality as poor, mediocre, good, or excellent based on the PRHISM score. We evaluated the agreement between the subjective assessments by experts and the PRHISM scoring classification. When assigning 1 to poor and 4 to excellent, the agreement was κ=0.54 (95% CI 0.45-0.64), indicating moderate agreement (Multimedia Appendix 6).

Evaluation of the Quality of Breast Cancer Treatment Information on YouTube in Japan Using PRHISM and DISCERN Score

Although this study primarily examined the utility of PRHISM, we also evaluated the quality of breast cancer treatment information on YouTube in Japan using PRHISM and DISCERN scores. The mean PRHISM and DISCERN scores for medical information related to breast cancer treatment on Japanese YouTube were 60.6 (SD 11.5) and 58.9 (SD 11.5), respectively (Multimedia Appendix 7).

Discussion

Principal Findings

In evaluating the quality of medical information on YouTube, the interrater agreement for the overall quality score of PRHISM was κ=0.52 (90% CI 0.49-0.55), and the primary end point was not achieved. However, the 90% CI for interrater agreement of PRHISM was superior to that of DISCERN, indicating that PRHISM is a more reliable metric when evaluating the quality of medical information on YouTube. In terms of validity, the agreement between the experts' subjective assessment and PRHISM overall quality was κ=0.37 (95% CI 0.14-0.60), indicating fair agreement. It was found that PRHISM has validity equivalent to that of DISCERN.

Although the primary end point was not achieved, 1 possible reason was the difficulty in setting the threshold and expected values for interrater agreement of PRHISM. In setting the threshold and expected values, we used DISCERN as a reference because no studies have examined the interrater agreement of PRHISM [7,10]. While the number of evaluators and videos was determined statistically, it is possible that a larger number

XSL•FO
RenderX

of both was necessary to adequately evaluate the quality of information. However, DISCERN was designed for books available in public libraries and bookstores, and leaflets produced by professional organizations and national self-help groups. We referred to studies that used DISCERN to evaluate medical information on social media, but many of them used a modified DISCERN with fewer evaluation items, making them difficult to reference [16-22]. DISCERN was not developed for social media, so the agreement may differ from previous studies. In fact, the agreement for DISCERN in this study, which focused on social media, was 0.45, lower than the 0.53 reported in previous studies [7] , suggesting that the threshold and expected values might have been better set slightly lower. Therefore, given the results obtained with this threshold, no definitive conclusion can be drawn about the robustness of PRHISM.

In previous studies, the agreement for DISCERN decreased depending on the profession of the evaluators [7]. In this study as well, a difference in agreement was observed depending on whether the years of experience were 10 or more, or less than 10. Although PRHISM is designed to allow for evaluation by nonexperts, these results suggest that evaluations conducted by experts may be more accurate.

We also examined validity. However, there is no gold standard for evaluating the quality of medical information. Therefore, it is necessary to establish a consensus among experts. During the development of PRHISM, the modified Delphi method, a consensus-building technique, was used. In addition, we assessed validity by setting alternative criteria. In previous reports, some studies have assessed validity based on guidelines and evidence [23] , while others have used expert evaluations as the standard [12,24] . In addition, there are studies that have used DISCERN as an alternative criterion. In this study, using expert evaluations as the standard, the agreement among experts was κ=0.54 (95% CI 0.50-0.57), showing a moderate level of consistency. However, the agreement between the experts' evaluations and PRHISM overall quality was κ=0.37 (95% CI 0.14-0.60), showing only fair agreement. Nevertheless, since the agreement was comparable with that of DISCERN, it suggests that PRHISM is also sufficiently valid for evaluating the quality of information. The lack of strong agreement may be due to the inevitable subjectivity of the assessments, leading to variations in judgments based on each expert's preferences and perspectives. In fact, the level of agreement varied among experts (Multimedia Appendix 5). It can be considered to have at least comparable validity to DISCERN, but there may be a need to consider how to use this tool regarding its validity.

Future Prospects

We aim to explore the use of AI to make the evaluation of medical information more objective, efficient, and with higher validity, allowing for the assessment of a larger volume of information in a shorter time. In fact, there are reports investigating whether AI can be used to evaluate online health information [25] . This study demonstrated that PRHISM is a suitable tool for evaluating the quality of medical information on social media. Therefore, this research serves as an important first step toward further investigations using PRHISM to assess the quality of medical information in various social media contexts. If low-quality information could automatically trigger warnings, it would help ensure that patients receive higher-quality medical information. Future research will explore the extent to which AI can be integrated into the evaluation process.

Limitations

This study has some limitations. First, the PRHISM overall quality is a metric independently established by the authors and was created specifically for statistical analysis. Since PRHISM is a tool that evaluates information using the PRHISM score or PRHISM scoring classification [10], the study may not directly evaluate the tool itself.

Second, there was a small sample size and a limited number of evaluators. Although a statistically valid number was considered, there was variability in the evaluations among the experts, potentially influenced by differences in their years of clinical experience. This indicates that a larger sample size and a more diverse group of evaluators with varying levels of expertise might be needed. To address this issue, future studies could include standardized training modules to improve consistency. In addition, integrating AI could automate certain aspects of scoring, reducing human bias and increasing efficiency.

Third, this study presents results solely from Japan. There may be an influence on the results due to biases in breast cancer treatment practices and expertise in Japan, as well as differences in medical environments. In addition, this study was limited to information about breast cancer treatment on YouTube, and the findings may not be applicable to other diseases or health-related information on different social media platforms. Similar studies need to be conducted in other countries and on different social media platforms. Although YouTube has regulations on posted videos, some reports indicate that the quality of health-related videos on YouTube varies widely, from low to high. Therefore, further research is needed to determine whether PRHISM is effective for evaluating content in other countries or on different social media platforms, as this will enhance its utility and relevance globally. We plan to conduct evaluations on other social media platforms.

Conclusions

PRHISM has greater reliability than DISCERN in evaluating the quality of medical information on social media, with comparable validity. It has the potential to become a standard metric for assessing the quality of medical information on social media.

Abstract

Background: Bipolar is a severe mental health condition affecting at least 2% of the global population, with clinical observations suggesting that individuals experiencing elevated mood states, such as mania or hypomania, may have an increased propensity for engaging in risk-taking behaviors, including hypersexuality. Hypersexuality has historically been stigmatized in society and in health care provision, which makes it more difficult for service users to talk about their behaviors. There is a need for greater understanding of hypersexuality to develop better evidence-based treatment, support, and training for health professionals.

Objective: This study aimed to develop and assess effective methodologies for identifying posts on Reddit related to hypersexuality posted by people with a self-reported bipolar diagnosis. Using natural language processing techniques, this research presents a specialized dataset, the Talking About Bipolar on Reddit Corpus (TABoRC). We used various computational tools to filter and categorize posts that mentioned hypersexuality, forming the Hypersexuality in Bipolar Reddit Corpus (HiB-RC). This paper introduces a novel methodology for detecting hypersexuality-related conversations on Reddit and offers both methodological insights and preliminary findings, laying the groundwork for further research in this emerging field.

Methods: A toolbox of computational linguistic methods was used to create the corpora and infer demographic variables for the Redditors in the dataset. The key psychological domains in the corpus were measured using Linguistic Inquiry and Word Count, and a topic model was built using BERTopic to identify salient language clusters. This paper also discusses ethical considerations associated with this type of analysis.

Results: The TABoRC is a corpus of 6,679,485 posts from 5177 Redditors, and the HiB-RC is a corpus totaling 2146 posts from 816 Redditors. The results demonstrate that, between 2012 and 2021, there was a 91.65% average yearly increase in posts in the HiB-RC (SD 119.6%) compared to 48.14% in the TABoRC (SD 51.2%) and an 86.97% average yearly increase in users (SD 93.8%) compared to 27.17% in the TABoRC (SD 38.7%). These statistics suggest that there was an increase in posting activity related to hypersexuality that exceeded the increase in general Reddit use over the same period. Several key psychological domains were identified as significant in the HiB-RC (P<.001), including more negative tone, more discussion of sex, and less discussion of wellness compared to the TABoRC. Finally, BERTopic was used to identify 9 key topics from the dataset.

Conclusions: Hypersexuality is an important symptom that is discussed by people with bipolar on Reddit and needs to be systematically recognized as a symptom of this illness. This research demonstrates the utility of a computational linguistic

XSL•FO
RenderX

framework and offers a high-level overview of hypersexuality in bipolar, providing empirical evidence that paves the way for a deeper understanding of hypersexuality from a lived experience perspective.

Introduction

Background

Bipolar is a severe mental health condition characterized by recurring episodes of high mood and low mood that is thought to affect at least 2% of the global population [1]. Clinical observations suggest that individuals with bipolar face difficulties regulating emotions and impairments to their cognitive processing, which can contribute to an association with high-risk behaviors [2], and research has demonstrated that these behaviors are often associated with a period of elevated mood [3-5]. Most of the existing research in this area has focused on trying to isolate the biological and behavioral mechanisms that drive risky behavior in people living with bipolar [2,6-14], whereas how these behaviors are exhibited in reality has been comparatively underresearched. Existing research presents a preliminary classification system for the types of risk-taking behavior that people living with bipolar may engage in [3], and through this study, we hope to contribute a more nuanced understanding of one facet of risk-taking behavior, the presentation of hypersexuality, based on large-scale social media data.

This research approaches hypersexuality through the lens of risk-taking behavior and as a symptom of bipolar, focusing on its potential to harm personal safety. However, hypersexuality is a complex concept lacking a universal definition and is shaped by cultural, individual, and situational factors. Perrotta [15] describes it as “a psychological and behavioural alteration as a result of which sexually motivated stimuli are sought in inappropriate ways and often experienced in a way that is not completely satisfactory” and further highlights that hypersexuality is challenging to diagnose due to the lack of established criteria and the impracticality of rigid diagnostic standards in addressing the subjective emotional universe of individuals. Walton et al [16] emphasize that diagnosing hypersexuality requires observable symptoms, subjective perceptions, adverse consequences, and distress. While it is included in the *International Classification of Diseases, 11th Revision*, as compulsive sexual behavior, the rejection of hypersexuality as a distinct diagnosis from the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, underscores ongoing debates about its classification, reflecting concerns about stigmatization and definitional challenges. The term *hypersexuality* may be used by some individuals to articulate personal experiences without negative consequences, and while these self-descriptions may not align with the definition adopted in this paper, they represent meaningful aspects of lived experience.

There are only a limited number of studies that have focused on the topic of hypersexuality and sexual risk taking in bipolar, and the literature on hypersexuality is sparse and not systematically defined [4,17-19]. Krantz et al [5] found that hypomania often precedes risky sexual behavior, with two-thirds of sexually active youth with bipolar engaging in behaviors categorized as above minimal risk and one-third reporting pregnancy, and Mazza et al [19] observed increased sexual interest in women with bipolar type I compared to bipolar type II. Raja and Azzoni [20] noted high awareness of sexually transmitted infection risks but prevalent risky sexual behaviors among individuals with bipolar, schizophrenia, or schizoaffective disorder, and Marengo et al [21,22] found a link between unplanned pregnancies and hypersexuality in manic episodes, also finding higher rates of casual and nonmonogamous sex among women with bipolar, including during euthymia. Krogh et al [4] explored the impact of mood swings on sexuality in bipolar through qualitative interviews, identifying 5 key themes: sexual drive, behavior, thoughts, intimate relationships, and identity. Their results suggest that elevated mood states increased sexual drive and interactions and that mood-related shifts had significant relational impacts. Observing the existing literature critically, a number of studies that have investigated hypersexuality in bipolar are >30 years old [23-25], making it “subject to the biases of sexual and gender norms” of those times [17]. There is also evidence of stigma attached to hypersexuality and the discussion of sexual experiences from health care professionals [26], as well as a lack of qualitative research into the sexual behaviors of people living with bipolar [4,27].

In this paper, we present a toolbox of computational linguistic techniques, including pretrained machine learning models for demographic inference, the extraction of key psychological domains using the 2022 version of Linguistic Inquiry and Word Count (LIWC-22; Pennebaker Conglomerates, Inc) [28], and unsupervised topic modeling using BERTopic [29], to provide an understanding of what kinds of topics are talked about in discussions regarding hypersexuality. This is the first study to use such methods on data that relate to hypersexuality in general and specifically to bipolar and demonstrates the utility of large-scale language analysis in health research. We acknowledge that there are serious ethical implications associated with the collection of such sensitive information but believe that the benefit of improved understanding and awareness that can be obtained using Reddit (Reddit, Inc) posts is of significant value to people who experience the symptom of hypersexuality as part of their diagnosis of bipolar. We provide a comprehensive outline of our ethical considerations, including consultation with lived experience experts, in the Methods section.

XSL•FO
RenderX

This research aimed to form the foundation for future work in the area by developing a dataset of qualitative information, addressing a significant gap in the field, and presenting key themes. The objective was not to provide an exhaustive analysis of all posts in the dataset as this lies beyond the scope of this study. Instead, the focus of this study was on the methodology used to construct the corpus and on foregrounding this topic as a critical area of scientific interest. We hope that this study supports calls for novel research to "address sexual symptomatology in bipolar within the context of current sexual, cultural, and gender norms" [27]. Our research questions are defined in the following section.

Research Questions

The research questions for this study were as follows:

- Is hypersexuality talked about on Reddit?
  - How can we recognize Redditors who post about hypersexuality on Reddit?
  - What are these Redditors' posting behaviors?
- How can computational linguistic methods be used for exploratory analysis of the Hypersexuality in Bipolar Reddit Corpus (HiB-RC)? This includes the following:
  - Psychological domains
  - Topic modeling

Methods

The Talking About Bipolar on Reddit Corpus

Application Programming Interface Data Collection

The posts in this dataset were collected using the Pushshift and PRAW application programming interfaces (APIs) in July 2022 through adaptation of existing code [30]. The 2 subreddits related to bipolar with the highest number of followers—r/bipolar and r/BipolarReddit (approximately 300,000 users)—were scraped to include data posted between July 2017 and July 2022. Applying a similar framework to those in the studies by Coppersmith et al [31], Sekulic et al [32], Cohan et al [33], and Jagfeld et al [34], we then used pattern-matching methods on this corpus to detect Redditors who self-reported a clinical diagnosis of bipolar using a framework implemented by Jagfeld et al [34,35]. We adapted this framework to identify self-reported diagnosis patterns from Reddit posts and comments that (1) contained at least one condition term for bipolar, (2) matched at least one inclusion pattern (ie, bipolar diagnosis of any type by a professional), and (3) did not match any exclusion pattern (eg, self-diagnosis).

After identifying posts from Redditors who had self-reported a diagnosis, we then collected the entire posting history for these users across all subreddits using a custom Python script (Python Software Foundation). This script collected the following information for each comment or submission made by a user: (1) post ID, (2) text body, (3) username, (4) subreddit, (5) post title (for main submissions and not for comments), and (6) time stamp.

We note that there are limitations to using self-reported diagnoses as these have not been clinically verified within the dataset.

Demographic Inference

Overview

To develop a more comprehensive understanding of the Redditors in our dataset, we used a number of methods for demographic inference (age, gender, and location) presented originally in the work by Jagfeld et al [34], Tigunova et al [36], and Harrigian [37]. While we acknowledge that these methods do not necessarily implement state-of-the-art technologies such as large language models, they are to date the only publicly available models for this type of demographic inference within the Reddit domain. Ethical considerations associated with using inference models are presented in the Ethical Considerations section.

Age and Gender

First, we manually identified self-reported instances of age and gender using the pattern-matching code provided in the work by Jagfeld et al [34]. These patterns identify self-reported instances of age and gender from submission titles, which are captured between square brackets as is typical notation on Reddit, for example, "I {28f} am posting here for the first time." Age was calculated using a function that estimates date of birth based on the age provided in the submission title compared to the submission posting date. Labels for gender were assigned using manual extraction for 675 users, and labels for age were assigned using manual extraction for 643 users. We then used pretrained models to determine age and gender for the remaining users in the dataset for whom a self-reported age or gender could not be determined. The pretrained models used for automated age and gender inference were developed by Tigunova et al [36], who presented a hidden attribute model using a convolutional neural network with attention mechanism architecture to develop representations of demographic information based on language use. The models were trained on similar domain data using the posts from >350,000 Redditors included in the RedDust dataset [36]. The reported accuracies for the age and gender algorithms are an area under the receiver operating characteristic curve of 0.88 for age and an area under the receiver operating characteristic curve of 0.91 and accuracy of 0.86 for gender [36]. Using a subset of gold truth labels that were manually extracted from the dataset for age and gender (675 users for gender and 643 users for age), we manually calculated a weighted F_1 accuracy of 0.8 for gender and 0.6 for age for our dataset. The text used as input to the models was preprocessed before being used as input, which involved cleaning the data to remove hyperlinks and non–English-language words and converting the text to the vector representation format expected by the model (adapting the scripts provided by Tigunova et al [36,38]). Both submissions and comments were used as input to the model provided that the content was between 10 and 100 words in length and that users had at least 10 posts that matched these criteria and using only the most recent 100 posts for each Redditor as input. The inference methods for gender that were used in this study were designed only to detect binary genders

XSL•FO
RenderX

(man and woman), the implications of which are discussed further in the Discussion section.

Geolocation

We used a pretrained model presented by Harrigian [37] to infer location identifiers for each user in the dataset at the country level. This model was trained using the distribution of words, posts per subreddit, and posts per hour of the day for Reddit users. When applying this model to our data, we included only users with >50 posts and up to 250 posts as specified in the documentation for the package to improve the accuracy of predictions [39]. The global model provided by Harrigian [37] was used, which achieves 35.6% accuracy, and as reported by Jagfeld et al [34], the accuracy is generally higher for users with more training data (95.1% for the United States, 65.1% for Canada, 82.8% for the United Kingdom, 44.1% for Australia, and 41.1% for Germany).

Developing the HiB-RC

After implementing the inference models, any users whose posting history did not satisfy the criteria for the pretrained models were removed from the dataset. This resulted in a snapshot corpus that contains data that span 13 years, with the earliest post dating back to June 2009 and the latest submission date in August 2022.

To detect posts with content related to hypersexuality, we created an initial set of seed terms to generate a subcorpus (the HiB-RC) of users with a self-reported history of hypersexuality. To develop this vocabulary of seed terms, we identified the keywords and phrases related to hypersexuality from a previous study that used lived experience interview data [3] and trained both word2vec (Google AI) [40] and fastText (Facebook's Artificial Intelligence Research laboratory) [41] embedding models on the Talking About Bipolar on Reddit Corpus (TABoRC) to find synonyms (words and phrases) and misspellings of these keywords and phrases. The fastText algorithm produces character-level embeddings that find numeric representations of words by looking at their character-level compositions, thus enabling us to detect common typographical errors for the hypersexuality seed terms. Traditional word- and character-level embeddings were deemed to be sufficient for this task as the embeddings were not being used as part of a predictive algorithm and, thus, there was a cost benefit in terms of lower computational and environmental cost for training these simpler models versus fine-tuning a contextual large language model. The final list of seed terms used to collect posts related to hypersexuality is presented in Textbox 1.

Textbox 1. Hypersexuality keywords used to create the Hypersexuality in Bipolar Reddit Corpus. These keywords were generated by finding the most similar terms to the input keywords using word2vec (Google AI) and fastText (Facebook's Artificial Intelligence Research laboratory) embeddings trained on the Talking About Bipolar on Reddit Corpus.

Input keyword to the word2vec and fastText models

- "Hypersexual"
- "Hypersexuality"
- "Hyper-sexual"
- "Hyper_sexual"

Output—*most similar* keywords

- "Hypersexual"
- "Hyper sexual"
- "Hypersexuallity"
- "Hypersex"
- "Hyper sexualised"
- "Hyper sexuality"
- "Oversexual"
- "Hyposexual"
- "Hyper sexualized"
- "Hypersexualized"
- "Overly sexual"
- "Hyper sexualization"
- "Hypersexualization"
- "Hyposexuality"
- "Hypersexuality"

XSL•FO
RenderX

At the early stages of data collection, we used a much longer list of seed terms to search for posts related to hypersexuality, including phrases such as "hook up with strangers," "high sex drive," and "threesomes." This list of vocabulary was generated using the same word embedding methodology but included a more diverse set of keywords as input when using the models to search for similar words and phrases. This resulted in a much noisier dataset where it was apparent after manual inspection that a large number of the posts were not written in the context of experiencing hypersexuality as a symptom but rather in the context of people sharing and discussing sexual experiences. Due to the infancy of this field of work and to avoid compounding the stigma regarding sex or incorrectly categorizing diverse sexual experiences as hypersexuality, we chose to refine the keyword list used as input to the word embedding models to words and phrases that directly related to the notion of "hypersexuality." We considered it more ethical to collect data from instances in which individuals self-reported the symptom of hypersexuality rather than inferring hypersexuality through more nuanced descriptions of sexual behavior. The result was that there was less ambiguity and greater reliability in the dataset of posts, with the disadvantage that we filtered out an unknown amount of data related to hypersexuality that talked about the topic in more nuanced ways. We refer in this paper to the concept of a corpus being "acceptably representative," whereby "we have to make do with studying merely a sample of the language use, or variety, as a whole" due to restrictions on time and resources and, in this case, ethical considerations [42].

After we had generated the final seed list of hypersexuality terms, we created a filter and applied this to the TABoRC. After preprocessing the returned posts to remove duplicates and only include posts that were >30 words in length, we manually annotated this dataset using the doccano tool to verify a post's inclusion in the corpus, with the posts annotated as confirming a hypersexuality report forming the HiB-RC. The corpus was annotated in full by DH, and circa 10% of the corpus (300 posts) was annotated by second and third annotators (SJ and PR). Interannotator agreement achieved a Krippendorff α score of 0.77 [43], and majority voting was used to solve annotator disagreements. Disagreements primarily occurred in cases in which an experience of hypersexuality was described but there was ambiguity on whether the author of the post was the one who had experienced the symptom. The annotation guidelines are presented in Multimedia Appendix 1.

Analysis Methodology

Interpreting the HiB-RC

To begin the exploratory analysis of our dataset, we produced descriptive statistics to detail the user and posting characteristics of the corpus. These analyses were conducted using Python, and the results are presented in the Results section to show demographic characteristics, the number of new users posting in the HiB-RC each year and the number of new posts referencing hypersexuality each year (using the TABoRC as a comparison dataset), and the top subreddits to which posts about hypersexuality were posted.

Linguistic Inquiry and Word Count

After exploring the Redditor characteristics of our dataset, we used LIWC-22 [28] to understand the key psychological domains within the HiB-RC.

LIWC-22 is a text analysis application that maps psychosocial constructs to words, phrases, and linguistic constructions [28]. Linguistic Inquiry and Word Count (LIWC) processes text using software and a dictionary, where the dictionary contains groups of words that relate to a particular domain (eg, positive or negative tone). Documents of interest (the input text) are analyzed by the software to map the domains to the text, calculating the percentage of each document that comprises words in these dictionary domains. LIWC was designed on the premise that the words that people use tell us about "their psychological states: their beliefs, emotions, thinking habits, lived experiences, social relationships, and personalities" [28]. The LIWC-22 dictionary is based on >12,000 words, phrases, and emoticons, and the authors describe that "in the advent of more powerful analytic methods and more diverse language samples, we have been able to build more internally consistent language dictionaries with enhanced psychometric properties" in this latest release of the software [28]. Modern text analysis has been influenced by >100 years of psychological research [44], and previous research has demonstrated how language analysis can provide insights into cognitive mechanisms, with "an increasing number of studies [which] demonstrate, [that] the ways in which people use words is reliable over time" [45].

LIWC domains have been used in various existing studies that explore how language is used by people living with bipolar, including as input for prediction and classification models [31-33,46-53] and exploratory analysis of mental health datasets [54,55]. In this research, we used LIWC to identify psychological domains that appear significantly more or less by comparing the HiB-RC to a control corpus formed of the same users' entire posting history across Reddit.

Modeling Hypersexuality

Egger and Yu [56] describe that social media data have opened up new pathways for scientific research but that the short and unstructured nature of the documents within social media datasets can cause methodological issues for analysis. The authors describe that topic modeling has increasingly been applied to the topic of social science, where topic models are defined as "probabilistic models for uncovering the underlying semantic structure of a document collection" [57].

Topic models seek to identify patterns between similar documents to add structure to an otherwise unstructured collection of text to facilitate exploration and understanding. Latent Dirichlet allocation (LDA) is one of the most widely used traditional methods for topic modeling and is a generative statistical model introduced by Blei et al [58]. Despite the popularity of LDA, the reliability and validity of the results have been criticized because there is no definitive method of model evaluation and there is a lack of guidance related to fine-tuning. The efficacy of LDA for analyzing social media data has been further criticized because the noisy and sparse

XSL•FO
RenderX

datasets generated in social science research often do not contain enough features for statistical learning [56].

More recent topic-modeling algorithms that have been implemented as an alternative to LDA [56] include embedding models [29,59] that rely on the vectorization of text data to locate semantically similar words and documents. BERTopic [29] is an algorithm that uses pretrained embedding models to create word and document embeddings so that documents that occupy similar vector space can be grouped together to form topics. By default, BERTopic incorporates Bidirectional Encoder Representations From Transformers embeddings and a term frequency–inverse document frequency algorithm, which compares the importance of terms within a cluster and creates term representation based on this [60]. This means that the higher the value is for a term, the more representative it is of its topic. Due to the sparse nature of social media data, BERTopic also includes a default module for dimension reduction using uniform manifold approximation and projection, which enables these dimensions to be reduced to the extent that hierarchical density-based spatial clustering of applications with noise can be used to identify dense regions in the documents [56,59].

On the basis of the comparison of topic-modeling methods presented in the work by Egger and Yu [56], BERTopic presents a number of advantages that influenced our decision to use this method in our research. These include its ability to perform well across multiple domains due to the use of pretrained embeddings and the fact that little to no preprocessing of text is required before training. There still remain limitations, which are described in the Discussion section.

BERTopic Setup

BERTopic was adapted for this study from the code provided by Grootendorst [61]. The parameters that had a significant impact on the topic output included the following:

First, KeyBERTInspired as the main representation input to the model. KeyBERTInspired [62] extracts representative keywords for topics using word embeddings, ensuring more context-aware representations. First, document embeddings are generated to capture the overall meaning of a document. Word embeddings are then created for N-gram words and phrases. Finally, cosine similarity is used to identify the words and phrases that are most similar to the document embedding. Textbox 2 shows the difference in representations produced using the default term frequency–inverse document frequency and KeyBERTInspired representation models.

Second, the use of *mxbai-embed-large-v1* sentence embeddings [63] as the pretrained embeddings for the model, which demonstrate very high performance for low memory use (ranked 13 in the Massive Text Embedding Benchmark leaderboard at the time of writing). We also tested topic generation using MentalBERT embeddings that have been trained on Reddit data within the mental health domain, but the resulting topic representations were less defined and noisier [64].

Third, a custom list of stop words were provided to the CountVectorizer module and, thus, excluded from clusters after training. This list included generic English stop words (eg, “and,” “or,” “this,” and “was”) as well as frequently occurring words such as “hypersex*” and “bipolar”—keywords that appeared in nearly every post due to the seed list of vocabulary used to generate the corpus or the topic domain.

Textbox 2. Default versus KeyBERTInspired representation of the example topics generated by BERTopic.

Default representation

- “Ve,” “manic,” “feel,” “really,” “don,” “mania,” “time,” “people,” “sleep,” and “know”
- “Age,” “years,” “sexual,” “older,” “csa,” “remember,” “trauma,” “know,” “young,” and “happened”

KeyBERTInspired representation

- “Hypomanic,” “manic,” “mania,” “depressed,” “depressive,” “depression,” “disorder,” “psychiatrist,” and “mood”
- “Abuser,” “abused,” “abuse,” “sexual,” “trauma,” “memories,” “rape,” “therapy,” “touched,” and “older”

After our model setup had been finalized, we manually merged similar topics after inspecting the posts included within each topic using the *merge_topic()* method of the model. Finally, we manually assigned topic labels for our topics to be used in visualizations and saved the model as a pickle file for future analysis. As noted when describing the limitations of BERTopic, the topics produced by the model may change each time the model is run. After altering the parameters of the model, implementing *mxbai-embed-large-v1* as the sentence embedding model, and using KeyBERTInspired as the main representation model, we found the generation of topics to be relatively stable with each iteration.

Ethical Considerations

We recognize the importance of developing an ethical framework when working with sensitive data that describe personal lived experience, especially when collecting data from a public site such as Reddit. We outline in this section our considerations regarding consent, anonymization, the right to be forgotten, and dataset retention. Our framework was informed by multiple sources, including institutional resources from the British Psychological Society, the British Sociological Association, and the UK government [65-67] as well as sources from academic research and guidelines [34,68-72]. This study was conducted as part of a PhD thesis on the topic of risk-taking behaviors in bipolar, and we consulted a panel of lived experience advisors through Lancaster University Spectrum Connect at the early stages of design. We also engaged with

XSL•FO
RenderX

Bipolar UK on a webinar on hypersexuality in 2024 [73] and sought invaluable guidance from lived experience researchers who coauthored this paper. Ethics approval was granted for the project by Lancaster University in December 2021 (FHMREC21042).

Reddit is colloquially known as "the front page of the internet," with >50 million daily users and 100,000 *active* subreddits in 2024 [74,75], and research has shown that the anonymity afforded by social media sites enables users to self-disclose on sensitive topics that they may otherwise find difficult to talk about [76]. As researchers, we wholly acknowledge that the Reddit posts used in our study contain sensitive information and that the forum users were not aware that their discussions would be used for research. We did not seek informed consent from the Redditors whose posts we collected due to the impractical nature of this task considering that the posts of >5000 Redditors were included in the TABoRC, but we note that Reddit users are made aware that their posts are publicly accessible through Reddit's terms and conditions. From a legal perspective, although Reddit is by nature an anonymous platform, we cannot know that Redditors do not use the same username across other social media sites or platforms, and therefore, we treat the information collected from the site as personal data. In accordance with the Data Protection Act 2018 and General Data Protection Regulation, an exemption for conducting research for "special purposes" would be relevant for nonconsent as we intend to publish our research and are confident that the publication of any research associated with the collection of these Reddit data "would be in the public interest" [67]. Further to the legal grounding of work conducted in the public interest, the motivation for this study was to learn more about experiences of a typically stigmatized symptom to identify how people experiencing hypersexuality could be better supported. There is existing evidence from lived experience suggesting that data on this topic can be difficult to access within a health care setting, so we acknowledge the limitations of using data sourced from the web but also recognize the unique insights that the analysis of such data can provide [3,27,77].

Following previous guidance [65,68,69], as we did not rely on consent for this study, we masked the usernames in this dataset (created alternative alphanumeric usernames for each Redditor in the dataset) and have only included paraphrased and depersonalized quotes in research outputs. We have also minimized the amount of qualitative data reported by using computational methods such as topic modeling and LIWC, which enable us to present key themes and insights from the data in an aggregate format without needing to rely heavily on quotes. Where we presented paraphrased quotes, we verified that Redditors could not be reidentified based on an internet search of the reworded quotes. Using these methods, we strived to maintain the privacy of the Redditors included in our corpus as much as possible.

We would also like to draw attention to the demographic inference methods that we used. Performing inference of such data enables us to offer predicted demographic information about the study population, which may allow for comparison to other domains, for example, clinical populations. Reporting on aspects such as gender also contributes toward more ethical natural language processing data collection as these predictions can suggest how experimental results might be generalized and also highlights where the data include bias [78]. However, inferring demographic information adds an extra level of personal data to the corpus, and we acknowledge that this comes with its own risks. The demographic data that we inferred are not intended to be used for identification or targeting of users in any way, and we understand that these inferred statistics are not 100% accurate, nor have they been used as features in any predictive models. The demographic data were only reported in aggregate format and will not be publicly released, although the code used is available open source. We would also like to strongly emphasize that any analysis reported using the demographic data indicates correlation and not causality.

Using Reddit as a primary data source is not "wholly problematic or must be ceased," but "careful handling and anonymization of such materials is of paramount importance for maximising ethical research practice going forward" [71]. We have decided to only publish redacted versions of both the TABoRC and HiB-RC with the UK Data Service, as requested by the funder of this research (the Economic and Social Research Council). The redacted versions of the datasets will include only the IDs for the posts that form the corpora. The corpora will be disseminated upon request on a case-by-case basis to researchers with an institutional email address, and future researchers will be required to access the content of the posts using an API. This complies with Article 17 of the UK General Data Protection Regulation and an individual's rights to data erasure because any content that has been removed since the creation of our datasets will appear as "[removed]" upon retrieving the post ID using an API.

Results

Posting Characteristics on Reddit

The TABoRC comprises 6,679,485 posts from 5177 users, and the HiB-RC comprises 2146 posts from 816 users. The demographic statistics for the TABoRC and HiB-RC corpora are presented in Table 1. The data suggest that >15% (816/5177, 15.76%) of the users in the TABoRC reported experiences of hypersexuality.

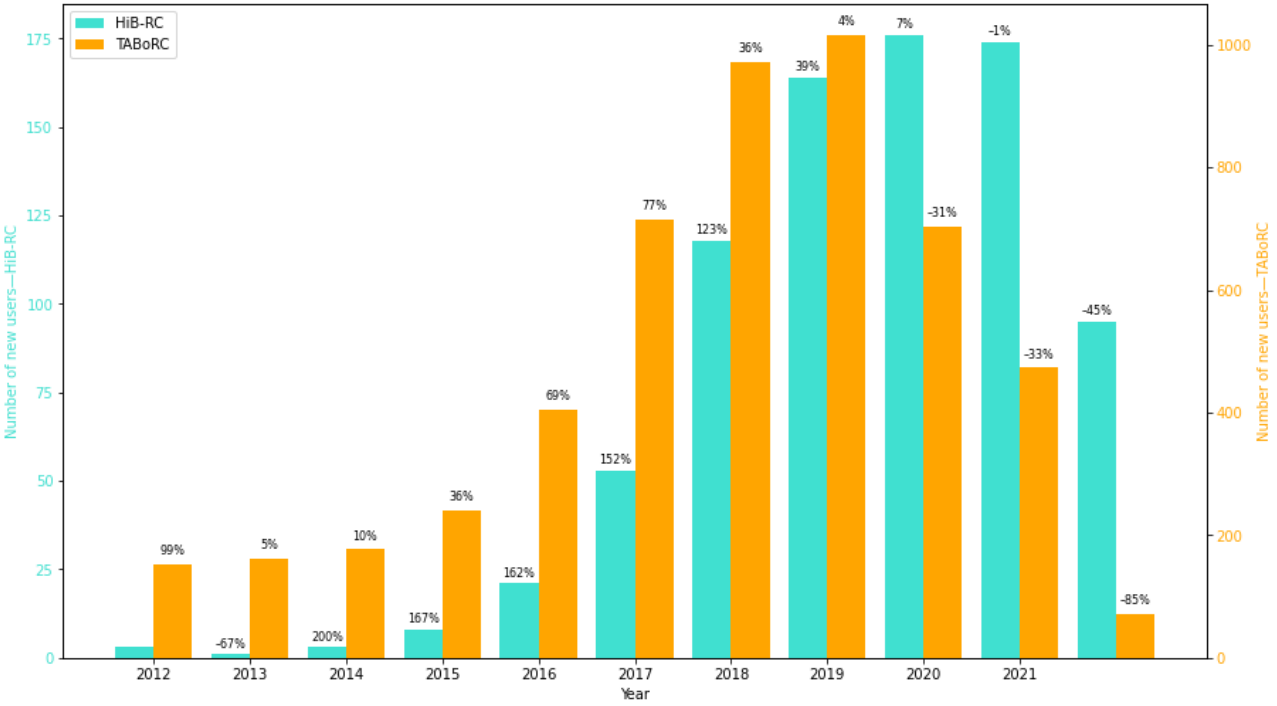
[a]The pretrained model [2] included an additional age category of 0 to 13 years (child). For any users who were manually or automatically included within this age group, we removed their data from the dataset as Reddit requires a minimum sign-up age of 13 years.



[b]Original data values were not provided with the dataset, so we have only presented percentages in this section.

[c]Not available.

Figure 1 compares the number of new users between 2012 and 2021 in the HiB-RC and the TABoRC, with an average yearly increase of 86.97% (SD 93.8%) and 27.17% (SD 38.7%), respectively. Figure 2 compares the number of new posts between 2012 and 2021 in the HiB-RC and the TABoRC, with an average yearly increase of 91.65% (SD 119.6%) and 48.14% (SD 51.2%), respectively. The bars represent the raw number of posts and the labels demonstrate the yearly percentage increase compared to the previous year. Table 2 shows how many posts that reference hypersexuality are made by each user.

Table 3 shows the top subreddits where posts related to hypersexuality were made within the HiB-RC (where >5 posts were made to the same subreddit), with the most visited subreddits including r/bipolar, r/BipolarReddit, r/bipolar2, r/AskReddit, and r/BipolarSOs.

Figure 1. Comparing the number of new users each year in the Hypersexuality in Bipolar Reddit Corpus (HiB-RC) and the Talking About Bipolar on Reddit Corpus (TABoRC). There is no percentage increase reported for the HiB-RC in 2012 because the first post in the HiB-RC was reported in 2012. Data collection ended in July 2022, so the observed trend in user growth may not fully reflect subsequent changes.

LIWC Results

Table 4 presents a selection of LIWC domains that were statistically significant when comparing the HiB-RC to a control corpus from the same users. The control corpus contains all posting history from each user in the HiB-RC across Reddit after removing the posts that are included in the HiB-RC. The total word count of the HiB-RC is 344,786, and the total word count of the control corpus is 69,495,570. We built the control corpus based on the hypothesis that these data would be representative of more general language use across Reddit by the same group of users based on manual inspection of a sample of the data. After identifying a nonnormal distribution in most LIWC domains based on paired scores using the Shapiro-Wilk test [79], we determined statistical significance using a paired Wilcoxon signed rank test [80] to identify significant differences in domain scores between the control and hypersexuality corpora. All domains included in Table 4 are significant at a *P* value of <.001. The table presents the Wilcoxon score and associated *P* value together with the effect size (Cohen *d*, with directionality represented by the minus sign [–]), which ranges between small (0.01 to 0.2) and huge (≥2) [81]. The methodology for the LIWC analysis was adapted from the work by Cohan et al [33].

[a]LIWC-22: 2022 version of Linguistic Inquiry and Word Count

[b]Positive direction indicates that the domain is more prevalent in the HiB-RC than the control corpus. Negative direction indicates that the domain is less prevalent in the HiB-RC than the control corpus.

BERTopic Results

Our implementation of BERTopic initially yielded 14 topics and 1 outlier class (which contained posts that were determined to be too noisy to accurately cluster into one of the topics by the algorithm). After manual analysis of these topics, we merged a number of similar clusters using the inbuilt function in BERTopic to produce 9 final topics (shown in Table 5).

Figure 3 shows how the representation of hypersexuality topics has changed over time, with all topics showing an increase in representation since the inception of the dataset.

XSL•FO
RenderX

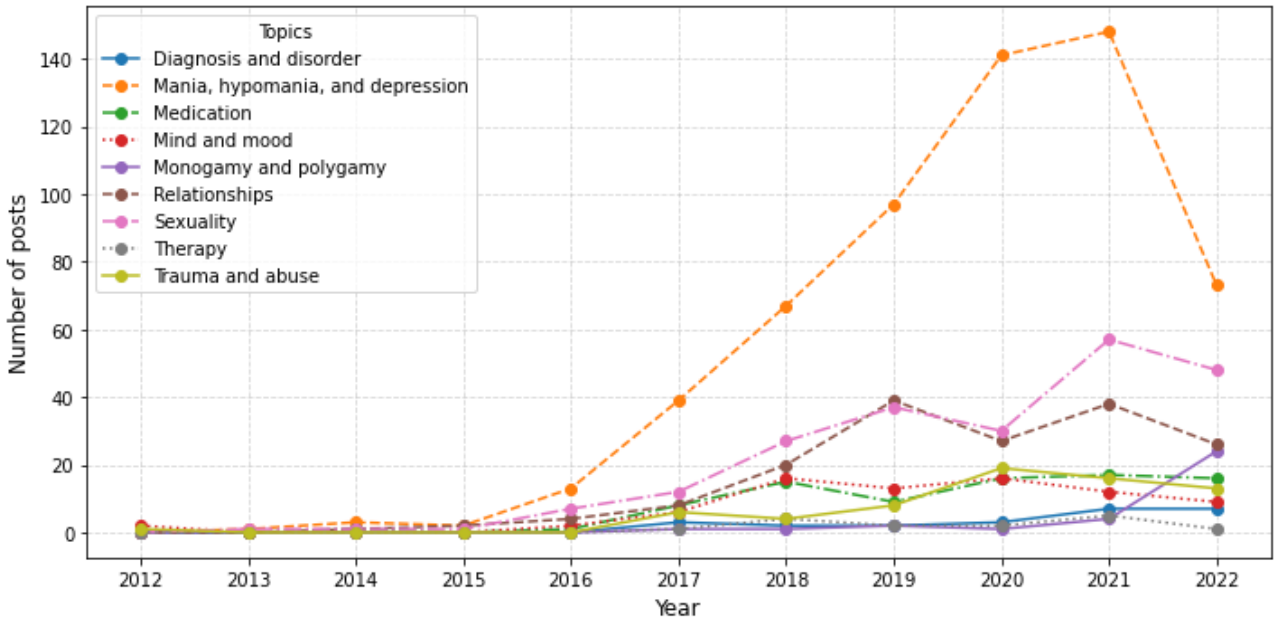

Table 5. Topics produced by BERTopic (with the manually inferred topic name), the top 10 keywords for each cluster, and paraphrased excerpts from the most representative post for each topic. Additional examples for each topic are provided in Multimedia Appendix 1 (n=2146).

Topic name (inferred)	Posts, n (%)	Top 10 keywords in the cluster	Extract from the most representative post for each topic (paraphrased)
__[a]	878 (40.91)	Outliers	—
Mania, hypomania, and depression	584 (27.21)	"Hypomanic," "hypomania," "manic," "mania," "disorder," "depressive," "depressed," "depression," "diagnosed," and "psychiatrist"	"Over 3-4 months, I left home, almost divorced, and indulged in reckless sexual encounters due to hypersexuality, hurting my family and behaving poorly. Reflecting on my manic episode, I now see the embarrassment and realize it's a common experience for many. As I came down, I recognized my strange behavior."
Sexuality	221 (10.3)	"Sexuality," "sexually," "sexual," "relationship," "feelings," "manic," "bisexual," "aroused," "feeling," and "boyfriend"	"I define myself as demisexual because I only experience attraction towards those I'm emotionally connected to, none of whom share the sentiment. Despite this, I have a strong sexual drive, feeling intense arousal monthly, and occasionally endure extended periods of hypersexuality lasting days or weeks."
Relationships	165 (7.69)	"Relationship," "relationships," "manic," "boyfriend," "disorder," "sexuality," "mania," "dating," "mental," and "diagnosed"	"I'm a challenging partner due to my manic episodes, leading to outbursts, bouts of hypersexuality (increasing the temptation to cheat), excessive drinking, and impulsive life-altering choices. Also, I believe I haven't completely healed from my previous abusive relationship."
Medication	83 (3.87)	"Hypomanic," "hypomania," "lamictal," "manic," "wellbutrin," "seroquel," "antipsychotic," "lithium," "zoloft," and "psychiatrist"	"In the last two months of taking it, there's been no improvement. Even after a week on 200mg, I'm still stuck in a severe mixed episode. I'm overwhelmed with hypersexuality, impulsivity, late nights, and a complete lack of motivation. My mood appears to be cycling rapidly, possibly even faster than before."
Mind and mood	76 (3.54)	"Hypomanic," "manic," "mood," "mania," "lithium," "feeling," "anxiety," "days," "thoughts," and "mind"	"I'm beginning to understand that although I experience cycling, my episodes often extend beyond a few days. Recent weeks of mood tracking reveal durations of a week or even two, with my current mood episode already lasting four days. In this most recent episode I've been feeling hypersexual, and like my head is full of thoughts. I'm also anxious and I've been focusing a lot on work."
Trauma and abuse	67 (3.12)	"Abuser," "abused," "abuse," "sexual," "raped," "trauma," "feelings," "memories," "therapy," and "touched"	"I started having cyber-sex with men in their 20s when I was 13, I would have online sex with anyone who was there, I wasn't thinking about their age. After this hypersexuality, I became very anxious and scared of men, and now I become very triggered when the topic of sexual abuse comes up."
Monogamy and polygamy	33 (1.54)	"Polyamory," "polyamorous," "monogamy," "monogamous," "relationship," "relationships," "poly," "married," "spouse," and "boyfriend"	"Following almost two decades of monogamous marriage, I divorced due to manic hypersexuality from bipolar, finding monogamy challenging. For five years, I explored different non-monogamous arrangements, aiming to find a new partner for monogamy. However, after another failed attempt, I encountered a married polyamorous man and chose to explore that avenue instead."
Diagnosis and disorder	24 (1.12)	"Disorder," "sexually," "sexual," "addiction," "manic," "adolescence," "mania," "psychological," "addicts," and "diagnosed"	"At 32, I was diagnosed with BP2, prompting reflection on missed signs in my childhood and adolescence. Back then, mental health wasn't a focus in my large family, and I concealed much of my struggles. With a BPD diagnosis too, distinguishing between disorders complicates understanding my experiences and symptoms. I completely relate to the hypersexuality. I have been very sexual since my early teens with a boyfriend who was years older than me."
Therapy	15 (0.7)	"Therapist," "therapy," "therapists," "counseling," "psychologist," "relationship," "intimacy," "psych," "helped," and "talking"	"I always remember them saying to never underestimate libido although that may not be the best advice for someone who's hypersexual."

Discussion

Posting Behaviors

The results demonstrate that natural language processing methods were successfully used to create a corpus of Reddit posts from users who had self-reported a diagnosis of bipolar and who created content that relates to hypersexuality. There were 816 users in the dataset who posted to Reddit about hypersexuality, forming a corpus of >2000 posts. While most of the users (453/816, 55.5%) in the HiB-RC had only posted about hypersexuality once (within the data that we collected), 44.5% (363/816) of the Redditors did post repeatedly about hypersexuality—which could indicate repeat episodes of hypersexuality or sharing the same experience across multiple threads. The data demonstrate that there has been a substantial increase in the discussion of hypersexuality in terms of both the number of posts and the number of users when comparing the HiB-RC posts to the TABoRC, suggesting that this is a salient topic being discussed on Reddit.

The data suggest that the HiB-RC encompasses approximately 15% of the Redditors from the TABoRC (816/5177, 15.76%), although the number of Reddit users who talk about hypersexuality more widely on Reddit is likely to be much higher than this. We make this assumption based on the fact that we used a restrictive set of keywords and phrases to retrieve posts related to hypersexuality, as discussed in the Methods section, and based on reports that 63% of women in a recent survey on experiences of bipolar reported hypersexuality as a symptom of bipolar [27,82]. Our dataset relied on Redditors who had self-reported a diagnosis and were already aware of the terminology of "hypersexuality," but we recognize that there is a large number of people who may be sharing their hypersexual experiences on the web before receiving a diagnosis using nonclinical terminology without knowing that this is a symptom of bipolar [27,77,82]. This is an important area of exploration for future research.

When comparing the demographic inference of the HiB-RC to data from a study that profiled Reddit users with a self-reported diagnosis of bipolar [34], our statistics for age and geolocation correlate. Most Redditors in the HiB-RC were based in the United States, the United Kingdom, Canada, Germany, and Australia (768/816, 94.1%) and were between the ages of 24 and 45 years (531/816, 65.1%). However, the inferred gender data for the TABoRC suggest that most Redditors were women (3668/5177, 70.85%), which is an interesting observation compared to findings that most Reddit users in general are men [83] and previous research on bipolar that identified a more equitable distribution of Redditors who present as men and women [34]. One interpretation could stem from different methodologies of data collection; we initially sourced our Redditors from subreddits that were specific to bipolar, whereas Jagfeld et al [34] sourced Redditors across Reddit from the outset. This notion correlates with research that Redditors who present as women are 33% more likely to post in mental health–related subreddits than Redditors who present as men [55] and, thus, we would assume are also more likely to self-report a diagnosis of bipolar in these subreddits. This gender inequality is further conflated in the HiB-RC (626/816, 76.7% of the dataset presented as women). While the interpretation of this statistic requires consideration of a number of sociological perspectives and a full understanding of this topic is beyond the scope of this study, existing research reports on the "sexual double standard" [84,85]. It is well documented that "behaviours associated with high sexual activity [are] expected more and evaluated more positively" [84] in men than in women, and therefore, it is conceivable that women could feel more stigmatized about hypersexual experiences and may be more likely to post in an online "safer" space [76]: "women must strike the right balance between what society deems to be too

XSL•FO
RenderX

much sex or not enough; men suffer from the pressure of performance" [77].

Finally, when considering where Redditors in the HiB-RC posted, we can observe that 77.82% (1670/2146) of the content was posted in subreddits associated with bipolar (r/bipolar, r/BipolarReddit, r/bipolar2, and r/BipolarSOs), suggesting that most of the Redditors in the dataset were aware that this is a symptom that is linked to bipolar. As described previously, this corpus is unlikely to be fully representative of the multiple and nuanced ways in which hypersexuality could be described on the web, and therefore, we should not misrepresent this statistic and assume that the wider population of people with a diagnosis of bipolar are aware of hypersexuality as a symptom. We also note that 7.88% (169/2146) of the posts appeared in the r/bipolar2 subreddit, which has typically been ignored in academic literature related to hypersexuality in bipolar [27,86].

LIWC Analysis

The significant LIWC domains presented in the HiB-RC yielded a number of interesting insights, of which we will only discuss the most salient in this section.

With reference to the *cognition* domains, posts in the HiB-RC were more likely to demonstrate *negative tone* and *negative emotion* and less likely to present *positive tone* and *positive emotion*. This is logical when we consider the potential impact that the symptom of hypersexuality can have on a person's life and correlates with the significantly higher presence of the *mental health* domain, which matches words such as *depressed*, *suicide*, and *trauma*. It is also logical that the *sexual* domain was significantly more frequent in the HiB-RC, where Redditors focused on sharing sexual experiences. For the domains of *reward* and *wellness*, we observed huge effect sizes of >−2, indicating that words such as *healthy*, *supported*, *gain*, and *benefit* (from the LIWC-22 dictionary) were significantly less prevalent in the HiB-RC, suggesting that Redditors do not view hypersexuality as a rewarding behavior. Finally, the domain of *past focus* was significantly more prevalent in the HiB-RC, whereby manual analysis of posts suggests that Redditors were primarily recounting histories and past experiences of hypersexuality. The significantly lower presence of the *future focus* domain correlates with this finding, as well as signifying the impulsive nature of hypersexuality that has been documented in the literature [77,86].

BERTopic Analysis

The clusters produced by BERTopic included 9 topics and 1 outlier class, and each topic was presented alongside a text excerpt from the most representative post (determined by BERTopic). Holistically, the model provided what we consider to be fairly distinct and identifiable topics, which is impressive considering the relatively small corpus and the niche domain of the dataset. Although topic modeling is not capable of capturing every nuance of the data, the model output provides a good starting point for understanding the data without needing to train a supervised model. The number of posts that were clustered into each topic by the model does not mean that these were the only posts that referenced a specific topic as some posts talked about more than one topic, and it is also likely that insightful data may have inadvertently been clustered into the outlier category. We can see that there was an increasing trend for all identified topics since 2017, which was especially pronounced for the topics of *sexuality* and *monogamy and polygamy* since 2020.

Evidence from the existing literature correlates with some of the topics identified by the automated model, including the onset of hypersexuality during an elevated mood [4,5,86], sexuality and sexual orientation [4,87], managing hypersexuality within a relationship [4,17], hypersexuality and medication [88-90], the role of child sexual abuse in hypersexuality [91-93], and vulnerability to sexual assault due to hypersexuality [27,77,82].

The Utility of a Computational Linguistic Framework

Current evidence from lived experience underscores the severe and multifaceted consequences of hypersexuality. These include risks such as sexual assault, unplanned pregnancies, vulnerability to sexually transmitted infections, traumatic abortions, and significant disruptions in personal relationships [82]. Findings from a Bipolar Commission survey involving >1500 individuals reveal that 88% of respondents experienced hypersexual behaviors, highlighting the symptom's prevalence and potential to impact thousands of people across the United Kingdom [27,94]. Over half of the participants reported experiencing ≥8 episodes of hypersexuality during their lifetime. Furthermore, 54% reported putting themselves in dangerous situations, 54% experienced relationship breakdowns, and 22% reported being raped during a period of hypersexuality. In total, 1 in 5 respondents attempted suicide due to hypersexual behavior or its consequences, aligning with previous findings that link hypersexuality in bipolar to increased suicidal ideation [95]. The data reveal a troubling gap in clinical practice, with 60% of respondents reporting that health care professionals had not addressed hypersexuality as part of their care [82]. This disconnect between the prevalence of hypersexuality and its clinical recognition underscores an urgent need for a more comprehensive understanding of hypersexual behaviors, particularly from the perspective of those with lived experience. The development of the HiB-RC and exploratory analysis using computational linguistic methods highlights the potential of this framework in advancing our understanding of hypersexuality as a symptom experienced by individuals with bipolar. The HiB-RC represents a significant resource for future research, enabling deeper exploration of the complex relationship between hypersexuality and bipolar to help bridge the gap between clinical knowledge and practice. The use of Reddit as a data source provides unique advantages, offering insights from real-time, user-generated narratives that are free from the constraints of predefined categories typically observed in self-report questionnaires or controlled laboratory settings [76]. This approach captures an authentic and dynamic perspective, reflecting the lived experiences of individuals as they occur. Future research using this dataset will use a corpus-assisted discourse analysis to explore key thematic concepts discussed by Reddit users and describe how these findings can inform and improve clinical practice for people with bipolar.

Additional avenues for future research could build on the exploratory nature of this study using alternative methodologies

XSL•FO
RenderX

to verify the findings and deepen insights. For instance, ethnographic or participatory studies could provide a more immersive understanding, whereas large-scale qualitative studies using interviews could triangulate the results. Applying the same computational methods to clinical datasets would offer valuable cross-validation. Collecting more detailed demographic information, such as relationship status, could also shed light on how hypersexuality manifests across different life contexts, enriching our understanding of this complex symptom.

Strengths and Limitations

This study offered a unique insight into the presentation of hypersexuality within a Reddit population who self-reported a professional diagnosis of bipolar. This is the first study to observe hypersexuality in such a population, and we endeavored to not only contribute to the literature on hypersexuality but also provide a rigorous and ethical framework for doing this. We used novel computational methods to identify salient patterns in the language used by Redditors, which signpost to common experiences shared by people who experience the symptom of hypersexuality. It is also important to consider the limitations of research conducted using social media data and predictive models, and these are outlined in this section.

First, as referenced in the Methods section, we relied on self-reported diagnoses of bipolar. As is the risk with any analysis conducted using social media data, we are assuming that the posts within our corpus are truthful. As described by Coppersmith et al [49], due to "the stigma often associated with mental illness," it seems unlikely that Redditors would post about symptoms of a mental health condition that they do not have. We also tried to reduce false-positive reports of a bipolar diagnosis in the dataset by using pattern matching to capture self-reported diagnoses by Redditors.

Second, we also acknowledge limitations associated with demographic inference. The first limitation is that the gender inference model was restricted to the binary prediction of men and women as there is no tool currently available that predicts beyond these two genders, and this is a limitation of the demographic predictions. A tangential avenue for further research could involve the development of a multiclass predictive model to avoid binary classification. Future research that involves the collection of primary lived experience data (eg, through interviews) should also focus on inclusive data collection to encompass a broader set of gender identities. The second demographic limitation that we would like to address is that most of the inferred geolocations were based in America, and although the data that we report are consistent with existing literature on hypersexuality and bipolar, we cannot assume that these findings will be fully representative of international experiences. For example, Redditors worldwide are likely to be affected differently by varying health care provisions, which could have an impact on experiences with access to psychosocial support and medication costs.

Third, there are a number of limitations associated with using an unsupervised topic model, including the generation of a large number of outliers and a lack of objective evaluation metrics (which is consistent across topic-modeling methodologies). The interpretation of the topic models generated by BERTopic also still relies on human interpretation and domain knowledge, but BERTopic does provide an option to use an "auto" parameter in the setup of the model, which reduces the number of topics by merging similar clusters after the model has been trained to produce the "optimum" number of topics (as opposed to defining *k* number of topics in LDA). Finally, due to the stochastic nature of uniform manifold approximation and projection (the dimension reduction algorithm used by BERTopic), the resulting topics produced by the BERTopic model may differ when running the same code multiple times [29].

Finally, as we have acknowledged throughout this paper, we used a restrictive set of keywords to search for posts that contained references to hypersexuality, and therefore, the data presented in this paper are not definitively representative of all experiences and understandings of hypersexuality in bipolar across Reddit. Future research could use word embeddings on the HiB-RC to identify words and phrases that appear in a similar context to variants of the lemma *hypersexual* and then search for these words in the TABoRC to return a large corpus of posts that potentially describe hypersexuality. To avoid confusing hypersexuality with experiences of increased sex drive or discussion of nonnormophilic sexuality [16], these posts would need to be manually verified for inclusion, and strict coding guidelines would need to be developed.

Conclusions

This paper has presented a novel methodology for generating a corpus of data related to experiences of hypersexuality in bipolar—inferring demographic information for these data—and 2 computational linguistic methods for exploratory analysis. We demonstrated that hypersexuality is an important symptom that is discussed by people living with bipolar, with significant associated factors suggested by the topic model, including the impact on relationships, discussion of medication, sexual assault, and correlation with an elevated mood. Our LIWC analysis demonstrated that posts describing hypersexuality were significantly more likely to include language that denoted mental illness and negative emotions, and we signposted to areas of further research that could be informative in guiding future clinical interventions. This study not only fills a critical gap by providing a dataset of experiences of hypersexuality within the context of bipolar but also highlights the potential of computational linguistic methods in mental health research. The findings underscore the importance of using innovative methodologies to bridge the gap between anecdotal experiences and empirical evidence, providing data that can help develop more informed and impactful psychosocial interventions in the future.

Acknowledgments

This study was completed as part of an Economic and Social Research Council Collaborative Studentship Competition PhD studentship (grant ES/P000665/1). The funder had no role in the study design; collection, analysis, or interpretation of the data; writing of the manuscript; or the decision to submit the paper for publication.

Data Availability

A redacted version of both the Talking About Bipolar on Reddit Corpus and Hypersexuality in Bipolar Reddit Corpus are available from the UK Data Service.

Authors' Contributions

DH designed this study, collected the Reddit data, and conducted the analysis. SJ, PR, FL, JP-C, CD, and AC provided comments and guidance throughout this study and provided valuable insights for the manuscript draft. PR and SJ performed second annotations for 10% of the Hypersexuality in Bipolar Reddit Corpus, and all the authors approved the final manuscript.

Abstract

Background: The rapid emergence of artificial intelligence–based large language models (LLMs) in 2022 has initiated extensive discussions within the academic community. While proponents highlight LLMs' potential to improve writing and analytical tasks, critics caution against the ethical and cultural implications of widespread reliance on these models. Existing literature has explored various aspects of LLMs, including their integration, performance, and utility, yet there is a gap in understanding the nature of these discussions and how public perception contrasts with expert opinion in the field of public health.

Objective: This study sought to explore how the general public's views and sentiments regarding LLMs, using OpenAI's ChatGPT as an example, differ from those of academic researchers and experts in the field, with the goal of gaining a more comprehensive understanding of the future role of LLMs in health care.

Methods: We used a hybrid sentiment analysis approach, integrating the Syuzhet package in R (R Core Team) with GPT-3.5, achieving an 84% accuracy rate in sentiment classification. Also, structural topic modeling was applied to identify and analyze 8 key discussion topics, capturing both optimistic and critical perspectives on LLMs.

Results: Findings revealed a predominantly positive sentiment toward LLM integration in health care, particularly in areas such as patient care and clinical decision-making. However, concerns were raised regarding their suitability for mental health support and patient communication, highlighting potential limitations and ethical challenges.

Conclusions: This study underscores the transformative potential of LLMs in public health while emphasizing the need to address ethical and practical concerns. By comparing public discourse with academic perspectives, our findings contribute to the ongoing scholarly debate on the opportunities and risks associated with LLM adoption in health care.

KEYWORDS

large language models; sentiment analysis; natural language processing; structural topic modeling; social media discourse; ethics, medical; health knowledge, attitudes, practice

Introduction

Artificial Intelligence (AI)-based large language models (LLMs) have sparked extensive discussions within the academic community since their 2022 emergence. The rhetoric is multifaceted, with rapt users touting the highly sophisticated chatbots' potential to assist in writing tasks. Critics caution, however, that the cultural and ethical ramifications associated with such reliance on LLMs may be a burden too costly to bear. Thus far, literature assessing ramifications of LLMs spans multiple fields, including finance [1], education [2], software programming [3], public health [4], and environmental studies [5]. These studies often focus on overlapping themes, that is, appropriate integration of LLMs, their analytical performance, and practical benefits for users. What seems to be missing is an examination of the nature of such deliberations. LLMs' societal impact ultimately relies on these users' verdicts, as warring technophile and luddite factions set the stage for successful technological adoption. To this end, our study assessed public opinion and perception regarding the most popular LLM widely available: OpenAI's ChatGPT.

This study specifically focused on health care, analyzing tweets that discussed the impact of ChatGPT on the health care sector since its inception and examined how ChatGPT interacts with various public health domains, including health care management, public health, digital health, clinical medicine, and nursing science [6-8]. We reviewed the opinions and sentiment shared on X (formerly known as Twitter) in order to answer the key question: Where does public and expert sentiment lie on ChatGPT's use in health care? Health care as LLMs technology has drawn recent accolade for the potential use, in part due to ChatGPT's recent accomplishment of passing the US Medical Licensing Exam [9]. Key concerns raised by the scientific community thus far include consequences of potential biases introduced in the LLM algorithm training

XSL•FO
RenderX

process, which may exacerbate the existing health disparities [10], spreading misinformation [11], and medical record breaches and cyber security [12]. In our current work, we aimed to understand how public opinions and sentiment about LLMs contrast with the opinions shared among academic researchers and other field experts to gain a broader view for the future direction of LLMs in health care. Through opinion mining, we identified 8 topics that represent general concerns and optimisms toward ChatGPT in health care. For the analysis and classification of twitters sharing positive and negative sentiments, we implemented 4 algorithms, determining their accuracy based upon a manual review of the tweets themselves conducted by our research team. We find our novel enhanced method that combines Syuzhet and GPT 3.5 had an 84% accuracy rate, 12 percentage points better than other classification algorithms used in our analysis.

The remaining article is ordered as follows: first, we state our research goal and key question underlying our analysis. Next, we state out our statistical methods. We then present our findings and discuss the implications for future research.

Methods

Ethical Considerations

To protect the privacy and confidentiality of study data, all IDs, usernames, and tweets have been deidentified. Additionally, any full tweets cited in the paper have been paraphrased to prevent them from being traced back to the original user.

Data Source

We used the academic Twitter API to retrieve tweets with search terms "ChatGPT AND (health OR healthcare OR hospital OR physician OR nurse OR nursing OR patient)" [13,14]. This data collection process was executed for the period between December 1, 2022, the day after ChatGPT became publicly available, and March 20, 2023. After removing duplicates using the Jaccard Similarity score [15], there were 6138 unique tweets authored by 4837 distinct accounts. The Jaccard Similarity is expressed as:

$$J(A,B)=|A\cap B||A\cup B|$$

where A and B are 2 sets, $|A\cap B|$ represents the number of common words between them, and $|A\cup B|$ represents the total number of unique words across both sets. The Jaccard score ranges from 0 to 1, where 0 indicates no similarity and 1 indicates identical sets.

It is worth noting that the academic Twitter API can be used to collect all tweets instead of just sampled tweets. Academic researchers are granted special access to the Twitter V2 API, which provides access to X's real-time and all historical public data (unbiased tweets). This API is no longer supported by X Corporation. However, users can still obtain full access to X through a paid subscription.

Sentiment Classification and Analysis Procedure

Our analysis consisted of three phases: (1) human-labeled sentiment tweet classification, (2) algorithm-based sentiment tweet classification; and (3) structural topic modeling (STM) to distinctly group tweet content. Each phase is detailed below.

Human-Labeled Sentiment Classification

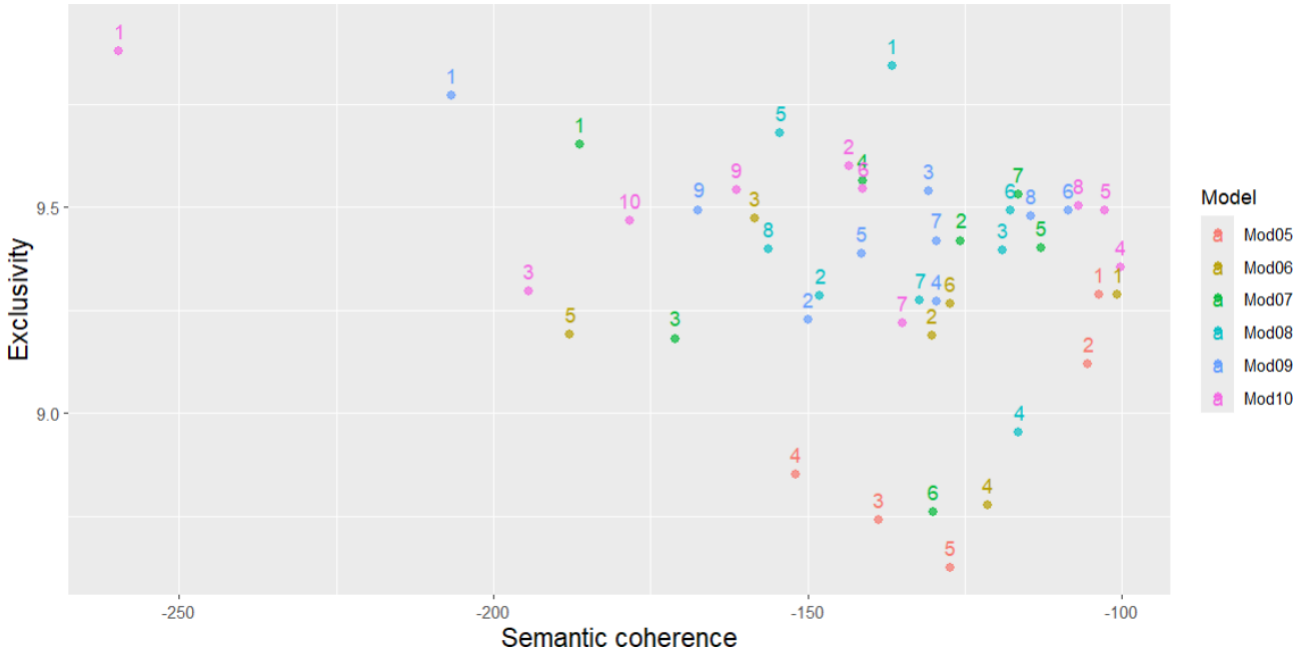
A team of 2 public health faculty members and two PhD students first reviewed each tweet and classified them into 3 mutually exclusive sentiment categories: positive, negative, and neutral. The team categorized tweet sentiment based on lexical content, context, emojis (eg, for positive, for negative), and tone. Positive tweets typically use words like "happy" or "love," while negative tweets include "terrible" or "hate"; neutral tweets lack strong emotions, informative contexts or advertisements. Each tweet was reviewed by 2 reviewers. If the 2 reviewers disagreed, the team discussed how to label the tweet in order to reach a consensus. Of the 6138 tweets, the majority of tweets were classified as neutral sentiment (4359/6138, 71%), while only a small percentage of tweets were classified as positive (1350/6138, 22%) and negative sentiments (460/6138, 7.5%). However, sentiment analysis models typically struggle with neutral context. Most of the collected tweets with neutral sentiment were those that included both positive and negative sentiments, potentially leading to misinterpretation of the results. Due to the inherent challenges associated with accurately interpreting neutral tweets, we excluded them from the analysis [16]. After removing neutral sentiment tweets, our final dataset contained 1806 tweets authored by 1586 distinct accounts.

Algorithm-Based Sentiment Classification

Next, we compared sentiment classification between 3 ML algorithms and those derived from the research team's manual review. These ML algorithms consisted of 2 of OpenAI's API models, Gpt-3.5-Turbo-0301 and Gpt-4.0, and the conventional dictionary-based Syuzhet method [17]. Both GPTs and Syuzhet can be used for sentiment classification, although they serve distinct purposes within this domain. GPT, generating text based on extensive pretraining text data, has a better understanding of context and is suitable for various tasks. In contrast, Syuzhet is specifically designed for sentiment analysis tasks and provides predicted labels based on its training on sentiment-labeled data. We used the Syuzhet package in R to evaluate the textual content extracted from the X data, tokenize the input text into words, then mapping them to predefined sentiment scores based on the chosen lexicon. For example, Syuzhet assigns a positive word (eg, love or happy) a+1and a negative word (eg, bad or terrible) a −1 and then adds them together for the sentence.

We explored the potential for enhancing the performance of algorithms by combining predictions from the Syuzhet and OpenAI GPT algorithms. Here, we identified the GPT algorithm with the superior performance, either GPT 3.5 or GPT 4.0, and then compared the GPT predictions with the Syuzhet predictions. If both the GPT and Syuzhet predictions exhibit the same direction, the predictions are retained and compared with the ground truth values. Each true match (ie, a tweet with the same algorithm and human labeling result) was considered a success, while contradictory results were considered an inaccurate algorithm classification. The accuracy rate was calculated as:

$$\text{Accuracy} = \frac{\text{True Positive} + \text{True Negative}}{\text{True Positive} + \text{True Negative} + \text{False Positive} + \text{False Negative}}$$



XSL•FO
RenderX

Application of STM

We used a STM to classify the tweets into distinct content topics discussing ChatGPT [18]. STM is a natural language processing and text analysis statistical technique that builds upon traditional topic modeling approaches, such as Latent Dirichlet Allocation [19]. Rather than simply identifying content topics, STM analyzes both the overall structure of the documents (eg, the arrangement of sentences, paragraphs, and other textual components) as well as the associations with other metadata (covariates). The approach allows for a more nuanced understanding of the topics, as well as how the topics relate to each other and to other contextual covariates. In this study, we incorporated 2 specific covariates, namely our human-labeled sentiment (positive and negative) and opinion leader status. The opinion leader covariate is defined by the number of followers associated with a given X account [20,21]. We categorize an "opinion leader" as an account in the top 10% (159/1586) of followed accounts, requiring at least 10,048 followers.

The STM method itself was an elaborative process. Initially, researchers arbitrarily determined the appropriate number of topics to batch the corpus content. We experimented with 5 to 10 topics (Figure 1). Once the number of topics was established, the STM algorithm proceeded to randomly assign topics to each word in every document within the corpus. The algorithm then refined these initial assignments iteratively by analyzing both the frequency of each topic's appearance in a document and the distribution of words within each topic. This dynamic process resulted in ongoing adjustments to the topic assignments for each tweet, while taking the probabilities of topic occurrences and word distributions into consideration. Two key measures determined the optimal number of STM topics: semantic coherence and exclusivity. Semantic coherence assesses how frequently words co-occur within a topic, reflecting the strength of their thematic connection. Topics with high semantic coherence contained words that often appear together, indicating a strong thematic link. Exclusivity quantified the distinctiveness of words within a topic, indicating how unique they are to that topic compared to others. Topics with high exclusivity contained words that are specific to that topic and rarely appear in other topics [18].

Figure 1. Comparison between exclusivity and semantic coherence.

After finalizing the topics, we evaluated each topic closely in order to assign a specific label to the topic. Further, we descriptively compared the opinion leaders' and nonopinion leaders' tweets.

Results

Comparison of Sentiment Classification Algorithms

Table 1 presents the results of sentiment analyses performed using: (1) human labeling; (2) Syuzhet; (3) OpenAI GPT 3.5; and (4) GPT 4.0. True positive and true negative cases are presented in bold in the table. As seen in the table, the model performed far better in predicting positive cases with the accuracy rates of 47% (Syuzhet) and 55% (OpenAI GPT 3.5 and 4.0). For the negative cases, OpenAI GPT 3.5 performed far better than the other algorithms with the accuracy rates of 9% (Syuzhet), 18% (OpenAI GPT 3.5) and 10% (OpenAI GPT 4.0). Consequently, for the overall accuracy, OpenAI GPT 3.5 outperformed GPT 4.0 and Syuzhet with the accuracy rates of 72.04%, 65.23%, and 55.82% respectively.

XSL•FO
RenderX

Table . Human labelling versus sentiment classification algorithms.

	Syuzhet			GPT3.5			GPT4.0		
	Negative	Positive	Neutral	Negative	Positive	Neutral	Negative	Positive	Neutral
Ground Truth									
Negative, n (%)	163 (9.03)[a]	165 (9.14)[b]	135 (7.48)[c]	316 (17.50)[a]	17 (0.94)[b]	130 (7.20)[c]	178 (9.86)[a]	15 (0.83)[b]	270 (14.95)[c]
Positive, n (%)	73 (4.04)[c]	845 (46.79)[d]	425 (23.53)[c]	43 (2.38)[c]	985 (54.54)[d]	315 (17.44)[c]	20 (1.11)[c]	1000 (55.37)[d]	323 (17.88)[c]

Evaluation of Structural Topic Model Results

Figure 1 demonstrates how these topics were assessed using semantic coherence (x-axis) and exclusivity (y-axis). This evaluation guided our decision in selecting the most appropriate models for clustering the tweets. Topics positioned near the upper right corner represent higher semantic coherence and exclusivity. The evaluation indicates the “Mod08” model, which consists of 8 topics, demonstrates both high semantic coherence and high exclusivity. In other words, Mod08 best embodies a strong thematic grouping with distinctive and closely related words compared to other STMs. The corpus was therefore divided into 8 topics for the subsequent analysis.

Table 3 lists the top 20 words with the highest probabilities that appear in the tweets classified under each of the eight topics. While most tweets focused on ChatGPT’s utility in the health arena, some tweets referred to the utility of ChatGPT in multiple sectors or industries, including the health sector. These tweets were classified under Topic 1. The tweets under Topic 2 predominantly focused on the potential and plausible future roles of ChatGPT in our daily lives with significant optimism. Under Topic 3, there were a number of tweets referring to the limitations of ChatGPT due to its sole reliance on data in making decisions. The tweets under Topic 4 referred to the utility of ChatGPT as an existing mental health service provider. Tweets classified under Topics 5 and 6 focused on plausible near future transformation in health care system (Topic 5) and services (Topic 6) triggered by ChatGPT. Topic 7 tweets also commented on future roles of ChatGPT in healthcare services, but the discussions were more on the concerns stemming from biases and inaccurate information identified in ChatGPT’s responses. Finally, Topic 8 contained tweets expressing positive sentiment about ChatGPT’s capability in improving clinical documentation’s effectiveness and precision as well as its availability to respond to medical questions around the clock, many of which referred to the possibility of physicians and other healthcare professionals being replaced in the near future.

XSL•FO
RenderX

Table . Top 20 words with the highest probabilities of each topic.

Topic	Top 20 words
Topic 1	health care, industries, industry, revolutionize, finance, applications, customer, revolutionizing, exciting, impact, possibilities, various, healthtech, development, efficiency, efficient, forbes, save, lets, delivery
Topic 2	potential, technology, improve, education, future, like, care, openai, artificialintelligence, new, see, ways, way, health, medicine, innovation, service, outcomes, world, work
Topic 3	time, tool, data, one, like, human, better, see, much, hospital, able, read, responses, day, school, never, imagine, dont, far, next
Topic 4	health, mental, can, support, using, advice, issues, used, people, chatbot, mentalhealth, users, public, provide, app, openai, chat, gpt, company, ethical
Topic 5	will, use, just, think, great, going, well, writing, already, take, amazing, change, cases, example, interesting, things, tech, field, many, cant
Topic 6	can, medical, patient, used, patients, language, treatment, tools, diagnosis, professionals, clinical, chatbots, intelligence, provide, help, artificial, models, accurate, data, large
Topic 7	can, help, even, care, get, people, may, information, doctor/s, patient, better, system, made, make, replace, way, want, wrong, like
Topic 8	asked, write, google, questions, patient, good, physician, answer, ask, still, using, lot, work, now, medical, best, doctors, say, need, asking

We reviewed all of the tweets under each of the topics and used these words as a supplement to label the eight topics as mentioned in Textbox 1:

Textbox 1. Eight topics.

- Topic 1: ChatGPT's potential in advancing various industries
- Topic 2: ChatGPT's potential in improving our daily lives
- Topic 3: Concerns related to ChatGPT's reliance on data
- Topic 4: ChatGPT in mental health services
- Topic 5: ChatGPT as text generator
- Topic 6: ChatGPT as an analytical tool
- Topic 7: Fairness in ChatGPT responses
- Topic 8: ChatGPT's potential in replacing healthcare professionals

Representative Tweets

We summarized each of the 8 topics identified via opinion mining and provided several representative tweets under each topic to demonstrate key points and discussions surrounding each topic.

Topic 1: ChatGPT's Potential in Advancing Various Industries

The 49 tweets under Topic 1 highlighted ChatGPT's potential to trigger significant transformations across various sectors, such as retail, health care, and entertainment, through real-time applications. Approximately 90% (44/49) of these tweets expressed a positive outlook. These tweets provided concrete examples of how these industries could benefit from advancements in AI and state-of-the-art technologies.

> *Across sectors like retail, healthcare, and entertainment, visual ChatGPT offers a range of real-time applications poised to transform entire industries.*
>
> *With advances in AI and other cutting-edge technologies, ChatGPT is steadily gaining traction in the market. Its integration into the healthcare industry? Absolutely possible.*
>
> *The impact of #ChatGPT across industries is already unfolding—from healthcare to finance, its potential is immense. As conversational AI continues to evolve, it'll be exciting to see what the future brings.*

Topic 2: ChatGPT's Potential in Improving Our Daily Lives

Topic 2 contained 355 tweets, with about 97% (344/355) expressing a positive sentiment. These tweets highlighted the

XSL•FO
RenderX

role of innovative technologies, such as ChatGPT, in improving various aspects of our lives, including health care and transportation. Well known figures, such as Bill Gates, have emphasized ChatGPT 's significance in revolutionizing office operations, health care, and education for better outcomes and efficiency. ChatGPT is seen as a pivotal innovation with the potential to reshape diverse domains and create numerous opportunities for innovation ecosystems. In summary, these tweets emphasize the transformative impact of AI technologies, particularly ChatGPT, in enhancing our daily lives and addressing pressing challenges, underscoring the opportunities they offer for innovation ecosystems.

> *It's exciting to see how #AI is enhancing our lives across the board—from healthcare to transportation. With technology on our side, the future is looking brighter than ever.*
>
> *Bill Gates believes AI—especially tools like #ChatGPT—is currently the "most important" innovation. AI technology offers powerful opportunities to boost efficiency and outcomes in workplaces, healthcare systems, and educational settings.*
>
> *In conclusion, ChatGPT is as a versatile AI tool with the potential to significantly improve many areas of our lives—from personal productivity and education to health, career growth, financial planning, customer service, and even virtual events.*

Topic 3: Concerns Related to ChatGPT's Reliance on Data

The 136 tweets under Topic 3 placed an emphasis on concerns related to the utilization of ChatGPT in health care applications. Approximately 43% (58/136) of these tweets conveyed a negative sentiment. A primary concern pertained to the feasibility of integrating ChatGPT into health care scenarios with limited patient data and the fiscal constraints imposed by insurance companies, thus underscoring the financial considerations associated with data acquisition. Another worry centered around the security of sensitive medical data, and risks associated with disclosing such information on public domain. In addition, doubts were expressed regarding ChatGPT's ability to offer appropriate medical advice. In summary, these tweets collectively highlighted concerns about the adoption of ChatGPT in health care services and advocated for a more cautious approach in handling sensitive medical data.

> *Feeding ChatGPT data equations, flowcharts, and calculations? That's the easy part. Now put it in a patient room—with a poor historian and limited information—and expect a clear answer? Good luck. Oh, and by the way—insurance doesn't always approve more tests. Data isn't free.*
>
> *Y'all, what are you doing? Treat any data you give to OpenAI like it's going on your public Facebook feed. Would you post patient info on FB? Then don't put it in ChatGPT. Would you share your company's financials on FB? Then don't feed them to ChatGPT either. Come on—this is rookie league stuff.*
>
> *I've been steering clear of (chat)gpt's hype—and turns out, I was right. Don't rely on ChatGPT for health advice. Tools like https://t.co/z0nixzpowi are far better for lit reviews and won't mislead you with false hope or questionable treatments.*

Topic 4: ChatGPT in Mental Health Services

Topic 4 encompassed 387 tweets, with approximately 52% (201/387) of them conveying a negative sentiment. These tweets shed light on the debates surrounding the utilization of ChatGPT in mental health applications. Supporters argued that ChatGPT could offer a valuable alternative to traditional therapy for individuals who face financial constraints or prefer remote interactions, thereby enhancing the accessibility of mental health services. Furthermore, health apps using ChatGPT as an AI health coach can provide personalized and round-the-clock assistance, potentially revolutionizing the field of health coaching. However, ethical concerns were raised, particularly in terms of informed consent. Some view experiments like Koko's use of ChatGPT for mental health support as ethically questionable. In conclusion, although ChatGPT shows promise in addressing mental health needs, it is imperative to carefully navigate ethical considerations and consent issues to ensure its responsible implementation in this domain.

> *ChatGPT has the potential to serve as a digital therapist for those who can't afford counseling or prefer to avoid in-person sessions. It could help expand access to mental health support for people who need it the most.*
>
> *A health app now uses ChatGPT to take the place of human health coaches—giving users round-the-clock access to an AI coach that offers clear, helpful support and advice based on their needs.*
>
> *I honestly don't see how an experiment like this could be exempt from informed consent requirements. It's flat-out #unethical. A company using #ChatGPT for mental health support without proper safeguards brings serious ethical concerns to the table.*
>
> *Here we go—Koko, a nonprofit focused on peer mental health support, ran a test using ChatGPT on its users without getting their consent. That's a serious breach of trust.*

Topic 5: ChatGPT as Text Generator

Topic 5 contained a total of 169 tweets, with the majority (132/161, 82%) reflecting a positive sentiment. These tweets highlight the growing recognition of ChatGPT's remarkable applications in various domains, particularly for remote health care delivery and summarizing virtual meetings. Its automation capabilities and ability to provide insightful summaries generated positive feedback from users, suggesting its potential to disrupt conventional industries such as consulting and academia. In short, ChatGPT is demonstrating its transformative potential across multiple domains, reshaping our approaches to writing, summarizing, and decision-making.

> *At our organization, we're currently experimenting with ChatGPT in the healthcare space—especially in delivering remote care globally. It's been helpful for*

XSL•FO
RenderX

> *generating automated summaries and transcripts of virtual sessions. At this point, its usefulness is hard to deny.*
>
> *The tools coming out of OpenAI are already shaking up the overpriced consulting world—and honestly, good! Just yesterday, a friend told me their buddy, who's on the hunt for a nursing job, was amazed at how much ChatGPT helped them craft a strong resume.*
>
> *Truly impressive—I asked ChatGPT how the #healthcare system might evolve after COVID-19, and it delivered a thoughtful response in just 3–5 seconds. It's clear that #academia needs to start engaging with this tool in a smart, thoughtful way.*

Topic 6: ChatGPT as an Analytical Tool

Topic 6 contained a total of 288 tweets, with the vast majority (268/288, 93%) conveying a positive sentiment. These tweets emphasized the crucial role of ChatGPT in health care decision-making and highlighted several key aspects. ChatGPT assists physicians with analyzing patient symptoms and medical history, facilitating diagnoses, and personalized treatment recommendations, and helping physicians make more informed decisions. Finally, ChatGPT serves as a valuable resource for lay people to understand medical conditions, drug interactions and treatment options, supporting decisions based on individual needs.

> *One way ChatGPT can support the medical field is by helping professionals consider possible diagnoses and treatment paths. By reviewing patient symptoms and medical history, it can suggest options that aid doctors in making more informed choices.*
>
> *ChatGPT can support healthcare by delivering fast, accurate responses to medical questions, aiding in clinical decision-making, and offering suggestions that reflect each patient's individual needs and situation.*
>
> *ChatGPT can assist doctors by offering information on medical conditions, potential drug interactions, and available treatment options—helping support their work in diagnosing and treating patients.*
>
> *Conversational AI can play a role in telemedicine by helping patients reach healthcare professionals and offering useful information about their health along the way.*
>
> *ChatGPT could serve as a source of reliable, up-to-date information on a wide variety of health topics—from common illnesses to available treatments and therapies.*

Topic 7: Fairness in ChatGPT Responses

There were 176 tweets categorized under Topic 7. Approximately 35% (62/176) of the tweets expressed negative sentiments. The negative tweets highlighted concerns about biases seen in ChatGPT's responses in health-related conversations. When requesting stories involving doctors and nurses, the AI often portrays nurses as women and doctors as men. Similarly, some professions are likely to be portrayed with a specific sex and performance reviews generated by ChatGPT tend to be more critical for female employees, exhibiting possible gender as well as role biases. In addition, some tweets acknowledged that small errors generated by ChatGPT could potentially cause serious harm to patients.

> *I asked ChatGPT for ten stories involving a doctor and a nurse. Only one featured a female doctor and a male nurse. Every story had a heterosexual pairing, and the names were overwhelmingly Anglophone—doctors named Alex, Jack, and Rachel; nurses with similar naming patterns. AI is still echoing bias, not representing reality.*
>
> *AI often mirrors the biases in its training data. Ask for a picture of a nurse, and you'll probably see a woman. Ask for a doctor, and chances are you'll get a man. This isn't just coincidence—it's a reflection of long-standing stereotypes baked into the data.*
>
> *ChatGPT tends to write longer and more critical performance reviews when it assumes the employee is a woman. It associates roles like nurse, receptionist, and kindergarten teacher with women, while seeing mechanic as male, and banker or engineer as male or neutral. These patterns show how gender bias can still surface in AI-generated content.*
>
> *The issue with ChatGPT is that it can still make mistakes—even in basic essays, including historical or factual ones. Sure, it might get 95% of the information right, but that remaining 5%? In medicine, that margin of error could cost a life. We're still years away from trusting chatbots in the operating room.*

Topic 8: ChatGPT's Potential in Replacing Healthcare Professionals

Topic 8 consisted of 266 tweets, and 29% (77/266) of them expressed negative sentiments. These tweets offered a glimpse into the various perspectives on ChatGPT's potential in substituting health care professionals. Some individuals believed that ChatGPT has demonstrated promising prospects in the health care arena and has the ability to generate text of human-like quality. For example, ChatGPT could transcribe patient audio and produce medical correspondence, possibly improving clinical documentation's effectiveness and precision. However, it is critical to acknowledge that ChatGPT is not a substitute for human expertise at this point. While ChatGPT can offer valuable assistance, particularly in generating high-quality human-like text, its performance in certain areas, such as health care real estate, is still inadequate. This implies that more refinement and development is required before it can completely replace human expertise in every aspect of health care.

> *Using OpenAI's open-source Whisper to transcribe patient audio, then running it through ChatGPT for responses—it's a setup that could be built at low cost and, frankly, might outperform your average BetterHelp therapist.*

XSL•FO
RenderX

I just fed some brief (fictional) patient notes into ChatGPT and asked it to draft a medical letter—the outcome was surprisingly solid. Honestly, it's getting close to dictation-level quality.

ChatGPT is out here solving problems we didn't really have. What I actually need is a system that makes healthcare affordable. Or a robot that can clean my place. Not a faster version of Google.

I ran some detailed healthcare real estate questions by ChatGPT—stuff I already knew the answers to—and it came back with a vague, off-the-mark response. Safe to say, my job's not going anywhere anytime soon.

Comparison Between Public and Opinion Leaders

Table 4 presents the number and percentage of tweets by opinion leader status. Overall, both groups exhibited similar tweeting patterns. Opinion leaders were, however, more likely to discuss: (1) ChatGPT's potential in improving our daily lives (Topic 2: 22.48% vs 18.01%); and (2) the possibility of ChatGPT replacing health care professionals (Topic 8: 20.18% vs 13.98%). In contrast, nonopinion leaders expressed more concern about the use of ChatGPT as an analytical tool in their daily lives (Topic 6:16.75% vs 10.09%). These findings illustrated the diverse perspectives and priorities within the ChatGPT discourse, underscoring the importance of considering multiple viewpoints when evaluating its impact on industries and daily lives.

Table . Comparison between opinion leaders' and nonopinion leaders' tweets.

	Opinion leader, n (%)	Nonopinion leader, n (%)
Topic 1: ChatGPT's potential in advancing various industries	2 (0.92)	47 (2.96)
Topic 2: ChatGPT's potential in improving our daily lives	49 (22.48)	286 (18.01)
Topic 3: Concerns related to ChatGPT's reliance on data	19 (8.72)	117 (7.37)
Topic 4: ChatGPT in mental health services	46 (21.1)	341 (21.47)
Topic 5: ChatGPT as text generator	16 (7.34)	153 (9.63)
Topic 6: ChatGPT as an analytical tool	22 (10.09)	266 (16.75)
Topic 7: Fairness in ChatGPT responses	20 (9.17)	156 (9.82)
Topic 8: ChatGPT's potential in replacing healthcare professionals	44 (20.18)	222 (13.98)

Discussion

Principal Findings

This study performed public sentiment analysis regarding ChatGPT's impact on health care. The findings provide several implications for both the deployment of LLMs in healthcare and the need for broader understanding of public opinion towards AI technologies in medical contexts.

The predominance of positive sentiment toward ChatGPT indicates a general optimism amongst X or Twitter users about the integration of AI into the field. This optimism was notably strong in discussions surrounding ChatGPT's potential to enhance patient care and health care decision-making, perhaps an acknowledgment of AI's capacity to process and synthesize large amounts of medical information quickly and accurately, which can support medical professionals in diagnosing and treating patients more effectively. In addition, users were excited about ChatGPT's availability to respond to questions.

Conversely, the areas of concern highlighted by the negative sentiments—primarily around mental health support and patient communication—point to critical ethical and practical challenges. Concerns of the reliability of AI-generated advice, the management of patient data, and the potential for perpetuating biases within AI algorithms are prevalent across topics. This suggests while there is readiness to embrace AI for certain technical tasks within health care, cautious public concern remains regarding the limits of AI's role in sensitive aspects of health care. Empathetic human interaction can and should play a crucial role in these areas.

The added sentiment classification accuracy of the enhanced ML approach is also worthy of note. Combining Syuzhet and OpenAI GPT 3.5 algorithm predictions resulted in an 84% accuracy rate, by far the best performing classification strategy we tested for our analysis. We theorized that by integrating the Syuzhet approach, which focuses on extracting the underlying emotional trajectory of a narrative with the predictive power of OpenAI's GPT 3.5. The model's synergy allowed for a more robust interpretation of data. Future researchers should iterate our approach with more sophisticated LLM models, like ChatGPT 4.0 or ChatGPT 4.5, to further enhance accurate sentiment analysis. The high accuracy rate implies that using both the GPT models and the Syuzhet package, researchers or policy makers can efficiently monitor public sentiment on emerging health crises and quickly analyze public health sentiment and meaningful insights on Twitter (or other social media) without extensive expertise in natural language processing. Also, recent studies on sentiment analysis of ChatGPT tweets typically use machine learning approaches for classification and require researchers to manually label tweets to create a training set [22-24]. The human labelling process is labor-intensive and time-consuming. In our study, we

XSL•FO
RenderX

demonstrated that pretrained LLMs are a potential tool to classify tweet sentiment without the need for manual labeling, significantly reducing the time and effort required by researchers.

Overall, public sentiments towards AI adoption in health care mirrored opinions found in academic literature. In particular, an abundance of literature has been published on ChatGPT's utility as a text generator (Topic 5). Here, a number of academic publications focus on the use of ChatGPT in scientific publications, which has led many journals and publishers to set new restrictions on the use of ChatGPT in generating manuscripts [25-28]. The main rationales for such restrictions are ChatGPT's "artificial hallucination", particularly in generating references that do not exist [29] as well as potential plagiarism for which non-human authors cannot be held accountable [30]. On the positive side, ChatGPT's usefulness as a generator of patient clinical notes and discharge summaries has also been explored and discussed by academics and health professionals [31-33] which corresponds to many tweets found under Topic 5. Racial or ethnic and gender biases as well as misinformation in ChatGPT's responses (Topic 7) are also noted in academic literature [34,35], and there is a general consensus in the literature that the challenge is likely to persist despite the use of more training data and novel algorithms [36].

Both academic literature and public tweets commented on the overconfidence of ChatGPT's responses in providing misinformation. Topic 6 (ChatGPT as an Analytical Tool) has also been widely discussed in academic and health professional communities as a potential diagnostic tool and a recommender and a potential decision maker of treatment regimens [37-39]. These studies conclude that ChatGPT's responses are mostly accurate on common, nonspecialized, topics, while, for specialized topics, the accuracy remains subpar. This aspect was not discussed in the tweets from the general public. Discussions about the negative consequences of limited training data (Topic 3) were seen ubiquitously as the major limitation of the currently available LLM in academic literature [36]. And the literature often perceived this issue as a long-term challenge. The literature unanimously states that health care workers cannot be replaced by AI (Topic 8), highlighting the importance of human-AI collaboration [40-42], while the general public was more likely to emphasize that human replacement is likely in the near future.

Finally, there is abundant literature on ChatGPT and mental health (Topic 4). Most of the academic literature on this topic focuses on the risks involved in mental health patients relying on ChatGPT. This was somewhat in contrast with the many tweets found on Topic 4 that highlighted the availability of ChatGPT as a provider of human-like interactions and personalized advice around the clock. The negative consequences discussed by the academicians and other professionals included escalation of self-isolation, which is known to lead to suicide or self-harm [43,44], risk of exposing sensitive personal information about themselves and their caregivers, which could lead to privacy violations [44,45], and ChatGPT's failure in capturing nonverbal cues and subtle human signals and its tendency to underestimate the suicide risk [44,46]. The literature suggests that ChatGPT is particularly not equipped to serve younger generation and children who are more likely to rely on the LLM applications [44,47]. Also, ChatGPT in childcare can easily provide false information. The collection of data from children raises significant concerns regarding privacy, security and the risk of potential data misuse [48]. Furthermore, informed consent is a fundamental ethical requirement for AI-driven mental health apps, as outlined in WHO's Regulatory Considerations on Artificial Intelligence for Health [49], which emphasizes the need for privacy and data protection, such as the General Data Protection Regulation (GDPR) in Europe and the Health Insurance Portability and Accountability Act (HIPAA).

In summary, we found that the general public is clearly privy to the main opinions raised by the academic community and health professionals, while the discrepancy in opinions was more notable in ChatGPT's capability as a mental health service provider as well as its potential as an analytical tool. For both topics, the general public was somewhat more optimistic or less specific in providing negative opinions. However, it is important to note that academic literature, which provides a more authoritative and evidence-based perspective, holds greater significance and value than public opinion in evaluating these aspects. Public opinion, while informative, often lacks the depth and rigor that scholarly analysis offers in these domains.

This study acknowledges several limitations. First, tweets often express a mix of positive and negative sentiment and may also contain advertisements. This complexity can challenge both LLMs and human analysts in accurately classifying them. Future research could address this by developing methods to categorize each tweet based on percentages of positive and negative sentiment, and by training LLMs to predict the likelihood of advertisements. Second, the vast number of LLMs (over 10,000) makes it impractical to test them all within a single study. Future work could involve building a centralized platform that stores LLM parameters and facilitates the replication of research findings. Third, the previously free academic Twitter API for collecting census data is no longer available. This necessitates exploring paid alternatives for future studies involving census tweets. Fourth, besides X or Twitter, other social media platforms such as Facebook, Instagram, and Threads can also serve as valuable sources of public opinion. However, accessing data from these platforms presents significant challenges due to strict privacy policies and data access restrictions. Unlike X or Twitter, where public data is more accessible, these platforms impose restrictions that limit large-scale data collection and analysis. More resources are required to collect data and analyze such variations in pattern. Finally, studying X or Twitter users may not fully reflect general public opinion, as the characteristics of X or Twitter users may not be representative of the general population. X or Twitter users from different backgrounds may exhibit varying behaviors. Also, our data do not allow us to assess differences in sentiment and opinion between health care professionals and patients. A comparative study focusing on these differences would be valuable to capture a full spectrum of perspectives. Thus, the generalization of our results to the general population should be approached with caution.

XSL•FO
RenderX

Conclusion

The public's cautious optimism serves as a call to action for both technological developers and regulatory bodies to prioritize transparency, ethical standards, and the safeguarding of patient data as integral components of AI development in health care. Ensuring these measures should not only build public confidence but also enhance the efficacy and acceptance of AI in the health care sector overall. Further, divergent opinions across different healthcare AI topics indicate further research is warranted to better understand where AI can best add value without compromising ethical standards. Future studies should continue to track such public sentiment discussion and its correlation with real-world AI integration outcomes in healthcare. Over time, deeper insights into how public perceptions will evolve, effectively guiding successful LLM adoption in the health care space.

Abstract

As we move beyond the COVID-19 pandemic, the risk of future infodemics remains significant, driven by emerging health crises and the increasing influence of artificial intelligence in the information ecosystem. During periods of apparent stability, proactive efforts to advance infodemiology are essential for enhancing preparedness and improving public health outcomes. This requires a thorough examination of the foundations of this evolving discipline, particularly in understanding how to accurately identify an infodemic at the appropriate time and scale, and how to distinguish it from other processes of viral information spread, both within and outside the realm of public health. In this paper, we integrate expertise from data science and public health to examine the key differences between information production during an infodemic and viral information spread. We explore both clear and subtle distinctions, including context and contingency (ie, the association of an infodemic and viral information spread with a health crisis); information dynamics in terms of volume, spread, and predictability; the role of misinformation and information voids; societal impact; and mitigation strategies. By analyzing these differences, we highlight challenges and open questions. These include whether an infodemic is solely associated with pandemics or whether it could arise from other health emergencies; if infodemics are limited to health-related issues or if they could emerge from crises initially unrelated to health (like climate events); and whether infodemics are exclusively global phenomena or if they can occur on national or local scales. Finally, we propose directions for future quantitative research to help the scientific community more robustly differentiate between these phenomena and develop tailored management strategies.

KEYWORDS

infodemic; information spreading; infodemiology; misinformation; artificial intelligence; information virality; public health; multidisciplinary; data science; AI; difference; challenge

Introduction

The definition of infodemic has evolved over the years. It started from being an "epidemic of information," as defined by Rothkopf in 2003 [1] in the context of the severe acute respiratory syndrome (SARS) outbreak, to then include the element of misinformation [2-4], especially when the concept gained momentum during the COVID-19 pandemic. Since then, thanks to the efforts of the World Health Organization (WHO) and collaboration with academics, infodemiology, that is, "the science of distribution and determinants of information in an electronic medium, specifically the Internet, or in a population, with the ultimate aim to inform public health and public policy" [2,5], has evolved from a primarily descriptive discipline into a more comprehensive field [6]. This transformation has integrated insights from behavioral, medical, and complex systems sciences, leading to a more comprehensive understanding that encompasses a broader range of phenomena and challenges.

From the earliest WHO reports on the COVID-19 infodemic and the global technical consultation of April 2020 [7], the infodemic was defined as "an overabundance of information—some accurate and some not—that occurs during an epidemic." Later definitions introduced the concept of information overflow [8], emphasizing the difficulty individuals face in identifying trustworthy information during crises. This broader conceptualization acknowledges that an infodemic extends beyond misinformation, as it is shaped by public concerns, information voids, and digital transformation processes that amplify content circulation.

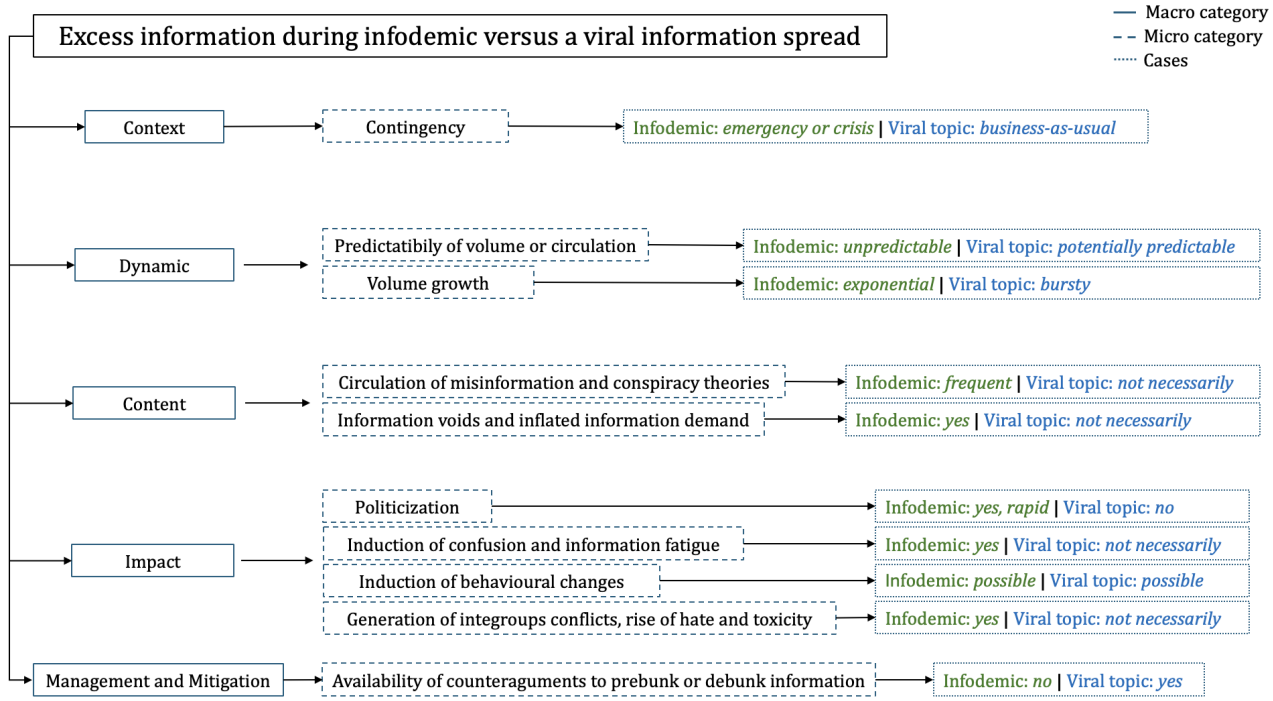
Recent discussions, including those from the Fifth WHO Infodemic Management Conference [9], have further refined this perspective, by highlighting the layered and multifaceted nature of infodemics. The conference underscored how infodemics emerge from a confluence of structural, behavioral, and technological factors, including the characteristics of the information ecosystem, the role of digital platforms in amplifying or mitigating information spread, the psychological

XSL•FO
RenderX

and social drivers of user engagement, and the dimension of trust in public institutions.

As digital platforms continue to evolve, new technological advancements further complicate the landscape: after the COVID-19 pandemic, the release of large language models to the general public raised discussions on the potential role of generative artificial intelligence in fueling future infodemics [10], adding another dimension to the challenge of managing information flows during crises.

While acknowledging this complexity, in this paper, we focus on one specific dimension of the infodemic phenomenon: the quantification of information production. By narrowing our analysis to this aspect, we aim to clarify how excess information during an infodemic differs from a general viral information spread. A more precise characterization of the quantitative aspects of information overabundance can help differentiate infodemics from other forms of information dissemination, guiding efforts to improve detection methods and to ensure that public health strategies can respond to crises in an even more informed manner.



The concept of an overabundance or excess of information, which underpins the current definition of infodemic, could be better described quantitatively by focusing on different aspects of information production and circulation. First, to our knowledge, there is broad recognition that individuals are continuously exposed to vast amounts of information, raising the question of how to benchmark overabundance. In other words, should it be measured with respect to content production regarding different topics of discourse or with respect to the same topic (assuming it was present in the debate) in a previous time window? Additionally, are different time windows comparable on social media, given the high turnover of users within digital communities? Second, should a spike in interest or a heated public discourse about a health-related issue happening on the web automatically be labeled as an infodemic or can it "just" be considered a noteworthy episode? And, further, can we provide estimates of the minimum lasting time for information overabundance to become an infodemic? In this scenario, we believe that understanding the differences between excess information during an infodemic and information virality can be useful to advance our understanding of infodemic processes. This distinction can inform the development of more precise indicators for enhanced infoveillance systems, enabling better monitoring and intervention strategies.

For these reasons, in what follows, we will list a set of key points that, building upon recent literature, differentiate excess information during an infodemic from a viral process of information diffusion and that could be turned, in certain instances, into viable measurements, with the aim of pointing towards new research directions. Instrumental to our purpose is to clarify what we mean by a viral process of information spread: a viral information spread or virality refers to the rapid and widespread dissemination of information or content, often through social networks and web-based platforms [11]. It follows that a viral process also generates an "overabundance" of information that, in theory, should be distinguishable from that generated by an infodemic in many respects.

Differences Between an Infodemic and a Viral Information Spread

In this section, we list a set of differences between the excess information observed during an infodemic and a viral information spread, considering up to 5 characterizing dimensions used for classification. Categories and differences are presented in a conceptual map in Figure 1.

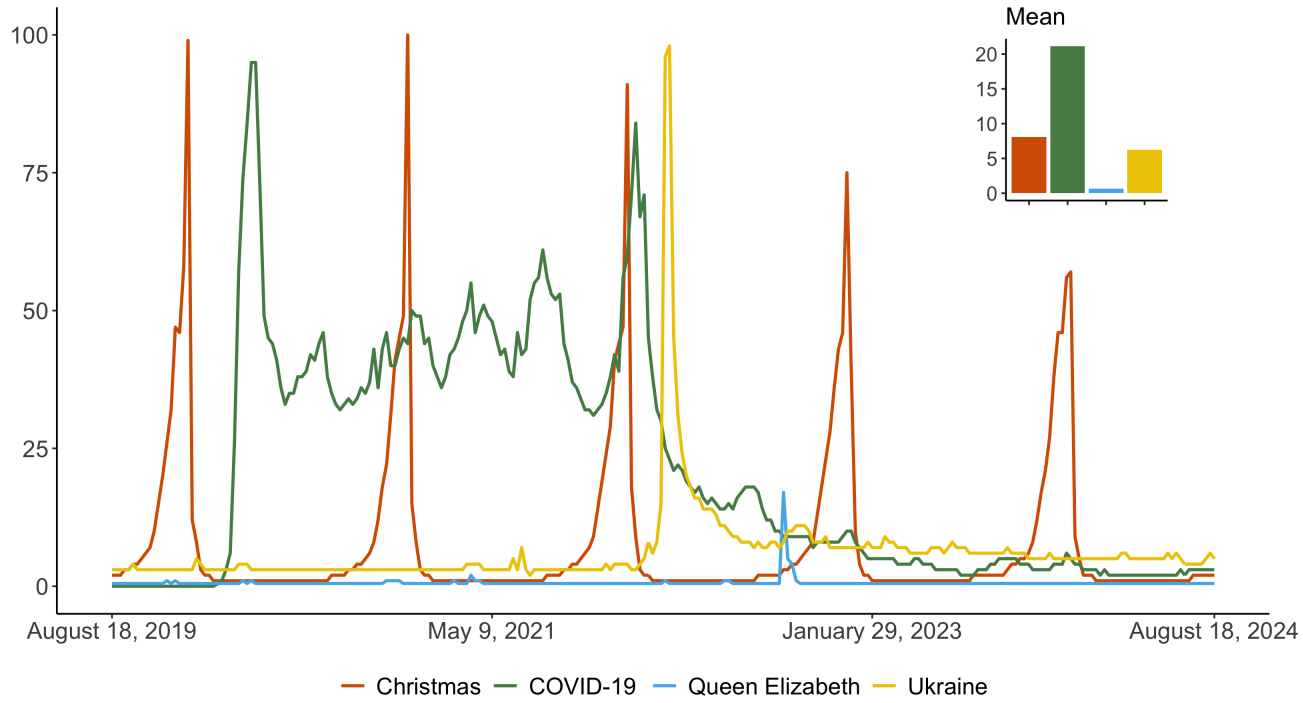
Figure 1. Summary of differences between excess information during an infodemic and a viral information spread.

XSL•FO
RenderX

Context and Contingency

An infodemic is associated with a (health) emergency or crisis, occurring in contexts where there is a heightened need for timely information and leading to an increased need for information dissemination to the public. In contrast, a viral topic may emerge during periods of "business-as-usual," meaning it does not necessarily coincide with any crisis or emergency. The timing and context of these events are crucial for differentiating an infodemic from a viral topic, with infodemics being crisis-driven and viral topics being more routine. However, in some cases, the initial magnitude of a health crisis may not be immediately clear, making it difficult to distinguish between a transient viral circulation of information and an evolving infodemic that could escalate in magnitude and impact.

Dynamic: Volume Growth and Predictability



The dynamics of how information spreads during infodemics differ significantly from those of viral topics. The production of information during infodemics is characterized by its unpredictable volume and spread. Content volume often grows exponentially during an infodemic and remains steady over extended periods. On the other hand, specific topics characterized by a certain seasonality or scheduled events of great resonance (eg, elections), that fall into the definition of virality, tend to have more predictable patterns. A similar reasoning holds for topics displaying sublinear, superlinear, or wavy behaviors in their volume growth, whose evolution, unlike in the case of infodemics, can be inferred by precise mathematical models [12,13]. However, any output by a forecasting model would require some initial input data, meaning that no predictions can be made until some pieces of content are released. It is also worth reminding that any expectation or prediction related to events in the social sphere carries a degree of uncertainty that depends on the contingency of exogenous events. Such uncertainty can lead to significant fluctuations in the phenomenon being studied, potentially rendering model predictions unreliable. This is a fundamental characteristic of complex systems and a key challenge in studying a constantly evolving society.

An example of the differences between viral topics and infodemics can be observed by comparing 4 cases or events that have gained substantial collective attention, namely the COVID-19 pandemic, the Russo-Ukrainian conflict, the death of Queen Elizabeth II, and Christmas. To illustrate this, and under the hypothesis that search interest in a topic correlates with content production [14], we used Google Trends data [15], which provide weekly time series of worldwide searches on Google over a 5-year period. We analyzed the search volumes for the following topics: "COVID-19," "Queen Elizabeth," "Ukraine," and "Christmas," though similar results were obtained when substituting "Russia" for "Ukraine." The weekly search volumes for these 4 terms were normalized on a scale of 0 to 100, where 100 represents the highest recorded search volume across all 4 terms, and 50 indicates half of that peak. A score of 0 indicates insufficient data.

From Figure 2, we can observe a clear difference between the 4 terms. While the death of Queen Elizabeth II gathered significant attention and became a viral event, its trajectory is markedly different from the other cases. COVID-19 shows a trend that takes about 6 weeks to peak, after which it continues to receive a high volume of searches over an extended period. The Russo-Ukrainian conflict presents a different pattern, falling somewhere in between the other 2 cases. Search volume peaks within approximately 3 weeks, followed by a decline to much lower, though still notable, levels—perhaps suggestive of an infodemic (note also that the situation in Ukraine is listed among the WHO's health emergencies [16]). Lastly, the case of Christmas serves as an example of a seasonal and thus predictable topic, which still falls within the definition of virality.

XSL•FO
RenderX

Figure 2. Time series of relevant topics including 1-time virality (Queen Elizabeth), seasonal virality (Christmas), infodemic (COVID-19), and infodemic-like (Ukraine). Data were obtained by searching keywords on Google Trends. The inset shows the average value of normalized searches for each keyword.

Content: Circulation of Misinformation and Information Voids

Content-wise, infodemics are frequently associated with a flood of mis- or disinformation and conspiracy theories, which is not necessarily the case with viral topics. During infodemics, the increased production of content co-occurs with the presence of information voids and inflated information demand [17,18], where gaps in credible information contribute to the uncontrolled spread of both accurate and misleading content. In contrast, viral topics do not necessarily involve such voids or demands, and the spread of misinformation may not be as prevalent.

Impact: Politicization, Confusion, Behavioral Changes, Social Cohesion, and Toxicity

The impact of an infodemic can be far-reaching. Infodemics tend to become rapidly politicized [19,20], with misinformation being shared and consumed as it aligns with the views of specific social and political groups. This rapid politicization is less likely with viral topics. Furthermore, infodemics can induce confusion and information fatigue [21-23] (sometimes referred to as information overload or infoxication), contributing to significant behavioral changes among individuals [24]. Viral topics, while they may also influence behavior [25], do not necessarily lead to such widespread confusion or fatigue.

An infodemic can erode social cohesion [26] by generating intergroup conflicts and increasing levels of toxicity in the public discourse [27]. This is a significant consequence of infodemics, fueled by the spread of divisive misinformation. Viral topics, while they may stir debate, do not typically lead to the same level of social disruption or rise in toxicity. At present, no systematic research has examined the correlation between topic virality and toxic speech usage. However, in the case of infodemics, researchers have observed a consistent association with toxic speech, starting with Sinophobia at the onset of the COVID-19 pandemic [27] and continuing with heated debates over vaccines in later stages [28], whereas in the case of viral topics, such occurrences have been limited to only a few instances [29,30].

Management and Mitigation: Availability of Counterarguments

When it comes to managing and mitigating the effects of infodemics and viral topics, a stark contrast emerges. During an infodemic, there is often a lack of established counterarguments, making it challenging to pre- or debunk misinformation [20]. In such situations, the scientific community may need to rely heavily on the best evidence available at the time due to the absence of consensus statements or previously established facts. On the other hand, for viral topics related to public health, such as vaccines, there is often an abundance of counterarguments from past debates that can be employed to address mis- or disinformation. These resources can also be effective in crafting prebunking strategies.

For instance, in recent years, a decline in coverage rates for the human papillomavirus (HPV) vaccine has been documented in Ireland [31], Denmark [32,33] and Colombia [34], primarily due to the viral circulation of web-based and social media content questioning the vaccine's safety profile. While one could argue that the spread of misinformation in these cases can be described as an infodemic, this characterization remains debatable due to insufficient data for measuring information overabundance in digital and physical environments. Instead, it can be more accurately hypothesized that these incidents represent a viral spread of misinformation. In some cases, the impact of this misinformation has been long-lasting. However, in most instances, the availability of robust safety data on the HPV vaccine has enabled public health agencies to conduct

XSL•FO
RenderX

communication campaigns that effectively restored public confidence in the HPV vaccine. By contrast, during the COVID-19 pandemic, public health agencies faced a tougher challenge in countering vaccine hesitancy, as they initially lacked real-world safety data to support their efforts.

Discussion

Open Points

As a concluding step, moved by the reasoning on the difference between excess information in an infodemic and a viral information spread, we discuss certain open points regarding the infodemic phenomenon.

Is an infodemic solely associated with a pandemic? Not necessarily; other health emergencies, as in the case of abortion [35], may generate an infodemic. Furthermore, health emergencies can arise from various factors beyond the spread of communicable diseases. For instance, the WHO includes events such as conflicts in Sudan and the neighboring countries [36] and other health and humanitarian crises [37] in the list of present and past health emergencies.

Is an infodemic limited to health-related issues? It is probable that future infodemics will arise during crises initially unrelated to health. For example, the increasing likelihood of extreme climate events over time may trigger prolonged (infodemic-like) debates fueled by various factors such as disasters or government interventions. In such cases, as crises are likely to touch every societal layer and health emergencies are deeply interconnected with socioeconomic and environmental factors, the health community would be anyway involved. Recent examples include the Israeli–Palestinian and the Russo-Ukrainian conflicts. On a related note, an infodemic might have also occurred following the launch of ChatGPT, an event that engaged a broad audience in the artificial intelligence debate, raising concerns and causing confusion about the role of this new technology in our future.

Is the infodemic exclusively a global phenomenon? Given that health emergencies and topics of public concern are not necessarily international (ie, they are not public health emergencies of international concern), an infodemic may occur at a national level or even at a more local scale. For instance, not all countries may be subject to an overabundance of information at the same time, switching in turn from an infodemic regime to a noninfodemic one. An example regarding the limited geographical reach of an infodemic may be represented by the previously mentioned case of the contagion of psychogenic reactions and the consequent HPV vaccine drop in Colombia due to the spread of videos, published on social media platforms, documenting false adverse reactions post vaccination [34].

Conclusion

In this paper, we have established a list of key differences that distinguish the excess information production during an infodemic from viral episodes of information diffusion. One key point is that the primary distinctions often become apparent in the medium to long term, including the overabundance of information, the protracted virality over time, the confusion of individuals, and the clear consequences for society. It follows that, in the shorter period, the two phenomena may appear somewhat indistinguishable, most likely as in the case of the transition from an epidemic to a pandemic. However, considering the vast amount of data and early signals potentially detectable on web-based and social media platforms, a significant phenomenon such as an infodemic cannot be regarded as something one realizes is happening as it occurs. This conceptual work aims to contribute to a better understanding of infodemics and information virality and may serve as a baseline for developing improved measures of information overabundance to support the multilayered process of infoveillance. In practice, possible efforts to measure the circulation of information during an infodemic could include developing causal models of infodemic evolution based on a series of independent variables, both epidemiological and nonepidemiological, to understand how non–health-related factors contribute to its progression. Establishing and utilizing appropriate baseline models to measure information overabundance across topics of similar and different natures would also be crucial. Additionally, leveraging the wide availability of viral web-based phenomena to create a set of case studies could help to compare the growth rates characterizing the initial waves of information diffusion of a new potential infodemic, thus providing reliable early warnings. While this may not be a primary concern for public health, it is valuable to highlight how different information-spreading processes may share certain characteristics (eg, overabundance) with the infodemic. Recognizing these commonalities could allow research to incorporate insights and practices developed in the study of infodemics into other contexts and vice versa, thus enhancing an always relevant multidisciplinary debate around this domain of knowledge. Future research efforts could shift the focus on how the dynamics of information consumption differ in infodemic versus viral contexts, as health-related content tends to have even less impact on behavior when individuals are not experiencing a personal, family, or social event that alters their need for information.

Finally, beyond serving as a checklist for infodemic recognition, the listed differences account for observations in the data regarding the COVID-19 infodemic and other topics, providing a challenging perspective that the public health community could employ to enhance existing infodemic management frameworks.

Abstract

In recent years, artificial intelligence (AI) has seen rapid advancements, with innovations such as large language models and generative AI evolving at a rapid pace. While this progress offers tremendous opportunities, it also presents risks, particularly in the creation, consumption, and amplification of information and its impact on population health and health program delivery. Thoughtful approaches are necessary to navigate the consequences of advances in AI for different health care professionals and patient populations and from a policy and governance perspective. Through a collaboration between the World Federation of Public Health Associations working groups, this Viewpoint article brings together perspectives, concerns, and aspirations from young adult professionals across 5 continents and from diverse backgrounds to explore the future of public health and AI in the context of the changing health information environment. Our discussion is divided into 2 parts, specifically examining aspects of disinformation and AI, and also the role of public health and medical professionals in a growing AI-driven health information ecosystem. This Viewpoint concludes with 5 key recommendations on how to potentially address issues such as information and disinformation overload; misinformation propagation; and resultant changes in health practices, research, ethics, and the need for robust policies that can dynamically address current and future challenges.

Introduction

Position Statement of the Authors

The World Federation of Public Health Associations (WFPHA) serves as a crucial global network uniting public health professionals and organizations committed to improving health outcomes and well-being worldwide. As a leading voice in global health, the WFPHA promotes public health advocacy, influences policy, and advances professional education across diverse regions. Within the WFPHA, the Young Working Group for the WFPHA (Young WFPHA) acts as a collection of medical and health professionals focused on empowering the next generation of public health leaders. Dedicated to fostering leadership, expanding career opportunities, and driving innovation, the Young WFPHA facilitates global collaboration among emerging professionals committed to advancing health and well-being. The group's vision is to ensure that young professionals are integral to building equitable and high-performing public health systems. The Young WFPHA, consistent with the mission of the WFPHA, is dedicated to equipping emerging public health professionals with the requisite skills and networks to address contemporary public health challenges, including in the context of new and emerging technologies. The Young WFPHA is also active in collaboration with various stakeholders and implements its mission through active engagement in prominent international health forums, including the World Health Assembly. In 2023, the Young WFPHA group conducted a detailed survey aimed at identifying the challenges encountered by early-career public health professionals. The findings identified major obstacles and concerns about the ability to navigate the expanding role of generative artificial intelligence (GenAI) in public health and health care design, delivery, and practice. This next generation of artificial intelligence (AI) tools presents both opportunities and challenges, requiring professionals to adapt and innovate in response to this rapidly evolving landscape. In response, the Young WFPHA partnered with the WFPHA Working Group on Global Health Equity and Digital Technology that focuses on research, education, training, and capacity building to ensure that digital technologies include health equity principles in their design, validation, implementation, and assessment. In this Viewpoint article, the 2 working groups bring together and elevate the diverse perspectives, concerns, and aspirations of young adult public health and medical professionals across 5 continents to explore the future of public health and AI in the context of the changing health information environment. GenAI can be defined as follows [1]:

> *Generative AI is artificial intelligence (AI) that can create original content, such as text, images, video, audio or software code, in response to a user's prompt or request.*

The Emerging Role of Generative AI

The area of AI, which is broad in scope and generally comprises technologies and a field of science that focuses on building computers and machines that can reason, learn, and act in a way that normally requires human intelligence, has seen significant advancements with the introduction of large language models (LLMs) and GenAI applications that are becoming increasingly accessible worldwide. GenAI is aggressively being incorporated by Microsoft, Google, and Apple across their products and services—concomitantly, Meta launched the largest open-source LLM, Llama 3.1. Subsequently, GenAI is being integrated into many aspects of daily life, from content creation (text, images, and music) to productivity tools (automation of tasks, customer service, and coding), data analysis (insights, reports, and trend predictions), and agentic AI models (chatbot agents) transforming our daily lives. Furthermore, GenAI has been shown to be promising in incorporating technically complex knowledge, as exemplified by OpenAI's ChatGPT's 98% score on a US Medical Licensing Examination Step 3 mock exam [2].

On the other hand, GenAI is, in essence, modes that generate output based on the patterns of content and types of language in the datasets that were used for its training. Therefore, the quality and accuracy of the model's outputs depend on the format, strategy, language, and knowledge base used in their training processes—when users use expert domain vocabulary, apply domain frameworks, and leverage domain context, they obtain better LLM outputs [3]. In specialized knowledge domains such as medicine, the implementation of LLMs in workflows is still nascent and will require improved evaluation approaches, consideration of prompt engineering, and understanding of human-computer interaction with the systems that incorporate GenAI, among other considerations specific to ensuring patient safety and improved health outcomes [3-6].

On the regulatory front, the G7 AI Principles and Code of Conduct have been established to guide the responsible and safe global use of AI. The European Union (EU) led the way with its comprehensive AI Act, positioning itself between China's strict regulatory controls and the more innovation-friendly, self-regulatory approaches of the United States and United Kingdom. In the United States, the "Safe, Secure, and Trustworthy Development and Use of Artificial Intelligence" executive order originally set the framework for regulatory approaches complemented by state-level and industry-specific regulations but has since been revoked by the new administration through an executive order in an effort to remove barriers to AI development [7-10]. Together, these emerging data and AI governance frameworks will be important to assess in the context of their implications for applications in medicine and public health.

The GenAI transformation will arguably impact all levels of society. McKinsey & Company [11] estimates that GenAI could add US $4.4 trillion annually to the global economy, although there are concerns about potential loss of employment across multiple industrial sectors. However, less understood is how GenAI could impact health information systems and broader information ecosystems already at significant risk from a trust and integrity standpoint following the global COVID-19 pandemic that was accompanied by an equally complex "infodemic." Tackling the challenges associated with infodemics during crises will be critical, particularly in the context of how infodemics in the age of polycrises can be mitigated or exacerbated by established or emerging technologies. We must also consider the broader challenge of the information

XSL•FO
RenderX

ecosystems and how diverse types of information—unclear, outdated, conflicting, and low-quality health information; misinformation; and disinformation (defined later in this Viewpoint)—impact health information seeking, understanding, and use, as well as health behaviors.

Infodemic refers to an overabundance of information, accurate or not, that occurs during a mass acute health event such as an outbreak, epidemic, or event of mass importance. It can lead to confusion, risky behaviors, and mistrust in health authorities [12].

Outside of the health emergency context, the work and impact of public health systems and health professionals is influenced by the structures and dynamics of the information ecosystem. The *information environment* refers to the dynamic set of *ecosystems* of all the communication channels, platforms, actors, narratives, and interactions that influence how individuals receive, process, and use and act upon information. With the digitization of information exchange and the ubiquitousness of information consumption, these rapidly changing information ecosystems are straining the capacity of public health agencies and programs to provide credible and accurate health information to clinicians, patients, and the public [13,14].

LLMs, GenAI, and other emerging AI technologies and computational systems (eg, quantum computing) present both challenges and opportunities for public health but are rarely designed or implemented with the priorities of public health outcomes, health, and well-being in mind or adequate governance of potential for "dual use" (ie, they could be directly misapplied for threats with potential consequences for public health and safety) [15]. Accordingly, a balanced approach to adopting the tools supported by AI advancements, ensuring that these are both innovative and responsible, is necessary and should be informed from diverse perspectives [16].

To address this complex topic, this Viewpoint article gathers perspectives from young health professionals who represent stakeholders who are crucial in shaping the future of how the public health community assesses, responds to, and introduces into practice these technology changes. Specifically, this Viewpoint will explore the specific opportunities and risks posed by GenAI in the health and information sectors through a collaborative consensus-making process and then conclude with a discussion of essential steps in education, training, research, innovation, policy, and ethics to better ensure the consideration of responsible AI advancements that benefit public health.

Approach Description

An initial draft outline of the manuscript concept was developed, followed by an open call for contributors based on the outlined topics. This call was disseminated among members of the Young WFPHA, leading to the purposeful selection of authors to ensure diverse representation in terms of geography and professional backgrounds. The participating contributors and coauthors came from Portugal, the United States, Nepal, Nigeria, New Zealand, Italy, Germany, and Brazil, representing diverse fields such as medicine, public health, medical informatics, and social psychology.

A collaborative approach toward generating consensus on main findings was used, with biweekly meetings where authors shared insights, proposed improvements, and agreed on new goals. For the 5 questions in part 2, each participating responding author independently and anonymously drafted and submitted their responses to the lead and first author. The latter then synthesized these responses into unified answers, which were then reviewed and refined by all authors until consensus was reached.

For the remainder of the manuscript, while all authors were encouraged to contribute to each subsection, each author was assigned the responsibility of compiling and integrating the content for their respective sections.

Part 1: The Dynamics of Information Ecosystems in Health Through the Critical Lens of AI Innovation

In the first part of our Viewpoint article, we assess the threats and opportunities presented by GenAI tools and applications, specifically concerning disinformation overload, AI-generated misinformation, and societal impacts.

Disinformation

Disinformation is deliberately promoted false information and can include hoaxes, conspiracies, and propaganda. Spreading health disinformation often exploits people's vulnerabilities for profit or political or ideological influence and inconsistencies in accuracy, relevancy, and context of the information. This can be driven by harmful commercial industries, fraudsters, or profiteers in sectors such as the tobacco, alcohol, food, wellness, and health supplement industries. Some actors spread disinformation to gain influence and monetize their audiences, advancing political or ideological agendas. For example, antivaccination groups use strategies such as donations, membership fees, advertising, and merchandise sales to fund their activities [17]. In addition, geopolitical actors use disinformation to weaken political opponents. Attacks on health systems through propaganda or cyberattacks undermine both the quality of health care and public trust in institutions, eroding people's sense of safety and social cohesion [18].

In today's digital age, people are bombarded with vast amounts of information daily through many channels and devices, leading to *information overload*—a state in which the sheer volume of information becomes overwhelming for people, making it difficult to process and make well-informed decisions. To manage this complexity, the brain uses *cognitive shortcuts* (or heuristics)—quick mental strategies that allow individuals to make judgments without needing to analyze all details [17-20].

Both information overload and cognitive shortcuts contribute to analysis paralysis—when people feel overwhelmed and avoid engaging with information critically. Political, economic, or cultural agents can exploit this unbalanced information environment to advance their agendas with limited transparency, taking advantage of trust erosion and belief confirmation bias—where individuals prioritize information that confirms preexisting views and dismiss contradictory evidence, therefore

XSL•FO
RenderX

making it harder to reach people with credible, accurate information [19-23].

In the *modern information environment*, human attention is treated as a scarce and valuable resource, which is sometimes called the *attention economy*. Platforms, content creators, and media outlets compete to capture the attention of their users, shaping how information is produced, distributed, and consumed to influence their users' behaviors and keep them on their platforms as long as possible to derive advertising revenue [24-31].

As public health strongly relies on the acceptance and adoption of evidence-based health behaviors by the broader population, dynamics arising from information overload–related phenomena can be particularly harmful—these dynamics impact not only individuals' health behaviors and the interpersonal and community relationships but also the health workforce, the health system, and the sociopolitical environment within which public health systems operate [32]. Regarding the latter, the politicization of health information also leads users to avoid critical thinking for selectively biased media content that can be amplified by platform algorithms [33-39].

AI-Generated Misinformation

Comparatively, disinformation may be understood as a subset of misinformation, distinguished primarily by its intentionality, which often makes it more insidious and damaging to public trust [40]. Misinformation can be defined as follows [41]:

> *Misinformation is when false information is shared, but no harm is meant.*

In the context of health-promoting behaviors and designed environments, understanding the continuum of elements in the information environment is essential to contextualize public health actions that aim to prevent harms to health and well-being [42]. This continuum starts with *questions* and *concerns*, the natural inquiries that people have during health crises. When these are not addressed, it can lead to *information voids* in which people search for answers but find none from credible sources. These information voids are situations in which people are especially on the lookout for health information, and when they fail to find it from credible, accurate sources, this creates fertile ground for exposure and susceptibility to *misinformation* (unintentional falsehoods) and *disinformation* (deliberate falsehoods), which can resonate with a person's innate values or preexisting attitudes or perspectives. People may share information online because it is aligned with their beliefs, values, and experiences, which they want others to see, and therefore, these prevailing beliefs can snowball into prevailing narratives that can undermine trust in public health systems.

The rise of AI-generated media and content (eg, deep fakes, news articles, statistics, photos, and infographics) makes it increasingly difficult to understand health information objectively and its relevance and trustworthiness, ultimately complicating communication of health guidance, health risks, and benefits of health interventions and programs [43,44]. Reflecting this risk, there has been a rise in low-quality AI-generated content on the internet, which has been referred to as *digital sludge* or *the funkification of the internet*, adding to concerns that low-quality AI-generated content will be further incorporated into general-use commercial LLMs, thereby diminishing the quality of LLM outputs over time [45].

Generating digital sludge is a strategy used by health-harming industries in marketing their products, with the alcohol industry being just one example [46]. Finally, the concept of disinformation itself might need to be re-evaluated given the challenges of attributing intentionality in the context of AI-generated content that may be mediated by user-led prompts, impacted by model hallucination, influenced by underlying training data or AI guardrails (eg, responsible AI frameworks or lack thereof and curated knowledge bases), or facilitated by agentic AI models that focus on achieving goals versus outputs. Inherently, these features of GenAI technologies make it harder to discern intentionality without understanding the intent of the human users who use these tools for engaging in health communication and information dissemination.

In addition to being used for content creation, GenAI models are being built into many web portals, internet platforms, apps, and devices, therefore impacting the quality of the information to which individuals are exposed. However, these applications often prioritize popularity or relevance over accurate data sources, potentially reinforcing the imprecisions of the algorithm or of the user's own preferences (which can be harmful, such as the promotion of ineffective treatments, amplifying health myths) as results are tailored to similarly situated users. An example of this challenge is the memory function of widely used GenAI platforms (eg, ChatGPT and Claude), which may skew a user's information knowledge base over time without the user noticing [47]. This can lead users to reinforce inaccurate perceptions of health information and become more likely to share disinformation, which, over time, can lead to greater communal exposure to conflicting or false information that can erode trust in public health authorities and exacerbate existing societal divisions [23,43,44,48-50].

This emphasizes the need to understand how the integration of AI technologies into our information environment without appropriate public health safeguards can skew users' perceptions and source accuracy, which demands a more nuanced approach to address not only the potential explicit harms of inaccurate narratives but also how the built information environment shapes people's understanding of health and well-being.

To mitigate the potential impact of GenAI-generated misinformation and in the interpretation of the built information environment, we propose a comprehensive approach:

1. Technological solutions; development of advanced algorithms to detect and flag deep fakes and inaccurate information [48].
2. Public awareness; promoting critical thinking and digital literacy to recognize misinformation among the public.
3. Regulatory frameworks; implementing regulations to hold the full chain of dissemination of false information accountable (eg, the recently approved EU AI Act mandates disclosure when interacting with AI) [49].
4. Collaboration; engaging with technology companies, media, health care professionals, and governments to identify and mitigate the impact of misinformation [51].

XSL•FO
RenderX

Societal Impacts

Mis- and disinformation are estimated to comprise 5% to 25% of the information environment and have wide-ranging impacts: psychological, physical, social, economic, and political [52-56]. Accordingly, these previously described information ecosystems—where sensationalist reporting, conflicting expert opinions, and slow issuance of health guidance create confusion among the public—undermine trust and enable misinformation exposure, endangering public health campaigns aimed at improving health outcomes [12,57,58]. For example, during a pandemic, this brings risks such as vaccine hesitancy and disregard for public health measures [58-60]. In addition, the health information system can lead to other behavior changes, with patients self-diagnosing more, requiring unnecessary and potentially harmful examinations and treatments, and possibly forgoing preventive or care options [61,62]. Finally, it is important to note that vulnerable communities (eg, those with low digital or health literacy or those who lack adequate access to health care services or coverage) are particularly susceptible to the deleterious impact of infodemics [63].

On the other hand, when combined with other strategies to strengthen public health surveillance, health promotion and education, and health informatic systems, GenAI has the potential to be an ally in the detection and mitigation of misinformation. For example, initiatives such as the health-related misinformation detection framework, SimSearchNet by Meta, and SynthID from Google DeepMind have the potential to act as agents for detecting health misinformation and AI-generated content, therefore being able to support the spread of accessible and accurate information [64-69]. In addition, GenAI may also be useful to understand geographical and temporal patterns of information and misinformation, analyze large datasets quickly for prevailing misinformation narratives that emerge from specific communities of interest, and better predict new trends and forecasts as health emergencies arise [70]. Furthermore, it has the potential through chatbots and other tools to enhance health literacy; accelerate information dissemination; support treatment adherence; enable early diagnosis; and contribute to disease surveillance, risk assessment, and mental health support if used appropriately and gated and guided by evidence-based information and ethical principles [71-74]. An example is the *digital health promoter prototype* Sarah, a GenAI chatbot and digital health promoter assistant developed by the World Health Organization (WHO) that provides guidance on healthy habits, mental health, noncommunicable diseases, and misinformation handling through online *face-to-face* conversations [75-82]. Examples of public health surveillance and health informatic systems include SIRVD-DL (Susceptible, Infected, Recovered, Vaccinated, and Deceased–Deep Learning) prediction model for COVID-19 surveillance, the WHO's Global Influenza Surveillance and Response System, and AI for Pandemic and Epidemic Preparedness, which could benefit from integration with AI tools to tackle global health challenges, including in the context of identifying and contextualizing the impact of misinformation on health outcomes [83]. Other uses of GenAI aimed to support health behavior change have focused on improving literacy, access, and operational efficiency in projects spread across low- and middle-income countries in both Asia and Africa (Jacaranda Health, Viamo, Girl Effect, Audere, and Noora Health) [84]. However, the utility of GenAI tools to carry out shared public health objectives and goals lacks sufficient evidence and requires additional research. The overuse of such tools may lead to an overestimation of their actual value as current evidence does not yet support their widespread implementation. Nevertheless, many enterprises are already integrating GenAI functionalities into everyday activities.

While technological innovation can help shape healthier information environments, it is crucial to address these challenges holistically considering the broader, governance, regulatory, social, and informational contexts that can be informed by young professionals, who will arguably be most impacted by the implementation of these technologies in current and future public health and medical settings [85].

Part 2: The Role of Public Health and Medical Professionals in LLMs and Information Ecosystems in Health

As discussed previously, the impact of the information ecosystem and mis- and disinformation on health and well-being in the GenAI era is vast and ever-evolving, with constantly new versions of LLM tools and systems that use them. Hence, it is crucial to take into account the views of young health professionals across various fields and regions to better understand current and future opportunities and challenges. We consulted medical doctors, public health professionals, and other health experts (researchers and psychologists) from 5 continents. The following sections present their perspectives through a unified response developed from the intersection of their individual blind answers.

What Roles Do LLMs Currently Play in Your Professional Area, and How Can They Enhance the Propagation of Safe and Reliable Health Information?

LLMs are transforming health care by automating administrative tasks; enhancing clinical, public health, and administrative data management; and supporting health education and research. Examples of solutions under development that integrate LLMs include patient education, automated medical record writing, and providing suggestions for patient diagnosis and management [86]. In public health, LLMs can aid in data treatment, contributing to predictive analysis and response strategies during health emergencies and conducting rapid contextualized analysis of community sentiment and health behaviors to generate infodemic insights and inform adaptive delivery of public health responses, programs, and communications. Despite these advancements, the integration of LLMs into health systems and public health practices faces significant regulatory and ethical challenges. For example, Health New Zealand – Te Whatu Ora has specifically advised against the use of GenAI in health due to concerns over privacy, accuracy, and ethics. To address these issues, the WHO has called for stronger evidence on the design, training, and validation of AI-supported applications, yet global regulatory frameworks remain insufficient to oversee the full life cycle of AI in health care and public health [87].

XSL•FO
RenderX

How Is the Integration of AI and LLMs Transforming Patient Communication and Overall Health Outcomes in Your Field?

AI and LLMs can transform patient-clinician communication not only in the consultation process but also by extending this communication beyond traditional consultation boundaries. These technologies can collect clinical information before appointments, handle administrative tasks such as record writing, and facilitate follow-up communications. If AI and LLMs can reduce the nonclinical workload of clinicians, this could allow health care providers to spend more time interacting with patients, thereby enhancing efficiency and quality of care. However, this productivity gain may only increase the number of patients seen without necessarily improving the quality of care.

In addition, if their current limitations and risks are overcome, GenAI tools have the potential to contribute to health promotion, risk communication, health education, and social behavior change efforts in public health systems. These technologies can personalize messaging, analyze real-time health data, and automate responses, enabling more targeted health education and behavior change interventions. AI can enhance risk communication by providing tailored, timely health warnings and support behavior change through internet-based counseling and interactive tools.

Furthermore, AI-powered tools are being tested to contribute to virtual counseling, adapted health information systems, and treatment adherence (eg, medication reminders) [88-90]. This can improve the patient-clinician communication and the care continuum, ensuring that patients receive comprehensive and continuous care. To facilitate this, such technologies could be integrated into previously developed digital solutions to make health care more accessible in rural areas, for example, through remote diagnostics and consultations in New Zealand and Brazil [91].

How Do You Plan to Integrate LLMs Into Your Practice, and What Specific Applications Do You Foresee?

LLMs' ability to process enormous amounts of data presents an opportunity to aid health care systems in managing patient outcomes. LLMs can transform previously unused data into actionable insights, enabling more effective management of patient outcomes. They can support clinical decision-making by providing clinicians with insights about patients in similar situations or generating concise patient summaries. If we can eliminate biases and other current limitations, LLMs can potentially identify patterns in patient data that may indicate a risk of developing certain conditions (digital twins), enabling early diagnosis and interventions, and remind patients and health professionals about regular checkups and screenings [92]. In this case, by analyzing and organizing large volumes of data, LLMs may facilitate regulated, accountable, and auditable data interoperability, increasing clinicians' effectiveness and accelerating access to patient information when necessary.

Furthermore, LLMs can improve resource management. For example, in Germany, one of the authors is working on a project that is exploring the integration of LLMs into nonemergency urgent care to help with patient navigation—this system determines whether a patient needs an in-person urgent care appointment, a telemedical consultation, or over-the-counter medication from a pharmacy or can wait until normal business hours for their general practitioner.

What Policies and Ethical Guidelines Do You Think Are Necessary to Responsibly Integrate GenAI Into Health Practices Worldwide (and Locally)?

The responsible integration of GenAI into health care requires robust global policies to avoid health risks, privacy issues, and biases (a study of a large US hospital database suggests that eliminating racial bias in triage algorithms would increase the percentage of Black patients who receive additional help from 17.7% to 46.5%) [93]. Thus, formulation of relevant policies and guidelines is urgently needed. Adherence to existing standards such as the General Data Protection Regulation (EU), HIPAA (Health Insurance Portability and Accountability Act; United States), and Lei Geral de Proteção de Dados (Brazil) is foundational. However, people living in countries without consumer protections are disproportionately affected by how commercial actors use their communities to develop, test, and deploy AI-supported tools, which may further exacerbate health and well-being inequities worldwide. Given the international nature of AI data markets, regional and national strategies should seek to align with global guidelines, with international organizations such as the WHO respecting the sovereignty of countries and the agency of individuals. Policies should balance innovation with patient safety and respect, ensuring practical implementation. The EU AI Act, for example, aims to create a comprehensive regulatory framework for AI, addressing risks and promoting ethical AI development and use within the EU.

Integration of these technologies must provide patients with easy options to opt out of data sharing without facing adverse consequences. In addition, specific consumer protection against deceptive marketing to vulnerable populations (eg, children), protection against hate speech, and protections of freedom of expression are essential. Furthermore, addressing the risk of propagating biases from training data is crucial as it impacts the fairness and accuracy of AI outputs. Ensuring inclusive and representative datasets is essential for equitable treatment of all patient groups. In addition, GenAI systems must be continuously validated in a transparent manner to increase data reliability, avoid issues related to copyright and intellectual property rights, and maintain trust and efficacy. In line with the Global Digital Compact, AI governance must be anchored in human rights and international law, with ethical guidelines, regular compliance reviews, and data security ensuring that these technologies benefit all [94-96].

What Future Impacts of GenAI in Health Care and Public Health Are Underexplored or Underestimated, and How Should the Health Professional Community Prepare for These Changes?

The future impacts of GenAI in health care are promising but need to be further evaluated for key public health areas: disease surveillance, prediction of disease outbreaks, assessment of

XSL•FO
RenderX

individual health risks, and suggestion of preventive measures. These advancements could lead to lower health care costs and better patient outcomes. In addition, GenAI has the potential to aid medical education through personalized learning experiences, virtual simulations, and real-time feedback. It can also streamline administrative tasks such as scheduling, billing, and resource allocation. Furthermore, in direct patient care, information from different centers remains highly fragmented worldwide. Patients often forget details about their medications, medical history, and previous treatments or surgeries. GenAI could help by securely integrating and condensing these data, reducing both missing and overlapping information, similar to what is being developed in the European Health Data Space.

While future health professionals will not need to be technology experts, they must effectively communicate with technology specialists. Therefore, every health degree should include GenAI training, including risks and limits, to prepare students for this integration. There will also be a growing need for professionals who can bridge management, technological, and health competencies to manage these complex systems, which can lead to work overload.

However, significant risks and challenges must be addressed. Public and ethical oversight, equity, and social participation are essential to prevent biases and ensure fair treatment for all patient groups and communities. Adequate resourcing of public communication; social participation; health promotion and health education capacities; and multilevel building of health, digital, information, and media literacies in communities and in the workforce is crucial. In addition, data sovereignty of peoples and nations (including indigenous communities experiencing inequities) is a crucial but underdeveloped area with important implications as AI progresses [97].

Policies must respect the data sovereignty of communities to ensure the ethical and equitable use of AI. These steps are necessary to foster acceptance and understanding of AI in health care.

Part 3: Discussion and Call to Action

In the third part of this Viewpoint article, we focus on summarizing the potential impacts of GenAI in various areas of society, with a specific emphasis on education and training, research and innovation, and policy and ethics.

While we are not specifically prescriptive, allowing for contextualized implementation and locally defined metrics, we aim to inspire actionable advancements across these areas. We also highlight that networks such as the WFPHA are well positioned to support these efforts, whether through capacity building, literacy initiatives, or collaboration on the responsible integration of GenAI into public health.

Education and Training

GenAI transformation is happening, and therefore, comprehensive training to future generations as well as to the current workforce is necessary. A commitment to maturation of AI literacy is necessary not only to improve the productivity of GenAI models and agents but also to ensure that consumers of GenAI-generated content are aware of its potential risks and biases and how to mitigate them [80]. In addition, health presents particular needs and serious implications for individual and community health, and therefore, specific continuous training for health and public health professionals should be prioritized.

Educational efforts must be comprehensive, addressing areas that continue to be debated in the GenAI space, including data privacy, policy implications, and algorithmic bias, while also promoting transparent and ethical design of GenAI systems and applications that are based on them. As previously discussed, promoting digital, media, and health literacy is central to infodemic resilience. This must be embedded into training programs for both the current workforce and future generations [29,54,98-103].

Therefore, we propose the following call to action: *increase health literacies (health, media, information, and science) and specifically AI literacy starting as early as preuniversity levels* to prepare future generations for the AI-driven health care landscape, as well as offering courses on AI use, risks, biases, and management of AI-generated information in all health degree programs. Similarly, we recommend integrating health topics into fields such as computer science, ethics, and technology governance.

Research and Innovation

While we understand the importance of research frameworks that address AI interventions, such as CONSORT-AI (Consolidated Standards of Reporting Trials–Artificial Intelligence), SPIRIT-AI (Standard Protocol Items: Recommendations for Interventional Trials–Artificial Intelligence), and the WHO's guidelines, we call attention to higher-level research needs that AI should support. Accordingly, we believe that AI research and innovation in health should prioritize three key areas: (1) ensuring universal and equitable access to accurate and high-quality health information (recognized by some organizations as a fundamental human right) by developing innovative strategies and digital solutions that promote informed decision-making and improve access to health care; (2) supporting preventive health programs using AI tools to enhance early detection, risk assessment, and health promotion efforts; and (3) combating polarization and bias in health information, ensuring that content delivered to diverse populations is trustworthy, inclusive, and culturally sensitive. Furthermore, while GenAI can significantly enhance research capabilities through advanced writing and data analysis, interdisciplinary collaboration is essential to prevent the spread of appealing yet inaccurate research results and misinterpretation or misrepresentation [104-106].

Therefore, we also introduce a call to action for *incorporation of AI and ethics experts within public health organizations* to ensure accurate and ethical AI application.

Policy and Ethics

Effective GenAI adoption in health care and public health requires collaboration among patients, civil society, and policy makers to establish ethical frameworks, regulatory oversight, and effective data governance. The Global Digital Compact,

XSL•FO
RenderX

annexed to the United Nations Pact for the Future, is the first global commitment to data governance—in addition to calling attention to the need to take local action by 2030, it incentivizes a global policy approach on AI governance and clarifies the need of this space to respect human rights and international law [96]. This urgent need for greater transparency and accountability is recognized by stakeholders from different backgrounds, from nongovernmental to corporate and philanthropic backgrounds (as exemplified by the Partnership on AI) [107-111].

A responsible transition depends on comprehensive yet flexible policy development (such as the EU AI Act), robust ethical guidelines (such as the WHO's "Ethics and governance of artificial intelligence for health: Guidance on large multi-modal models"), and a strong commitment to ensure health equity [49,112]. These are vital to avoid biases in AI models and ensure that GenAI benefits are distributed fairly.

Regarding ethics, the WHO has outlined 6 ethical principles to guide AI development in health: protecting autonomy, promoting well-being and safety, ensuring transparency, fostering accountability, ensuring inclusiveness and equity, and promoting sustainability [112]. WHO ethics guidance will soon extend to provide help and capacity building to public health authorities to establish infodemic management practices, policies, and strategies [113]. These guidelines emphasize the importance of fairness, transparency, and accountability, addressing critical concerns such as data privacy, algorithmic bias, and health equity to prevent AI from deepening existing health disparities. Finally, the recent adoption of the WHO Pandemic Agreement, aimed to set a global standard for pandemic prevention, preparedness, and response, does not contain specific reference to infodemics or dis- or misinformation but does recognize the importance of trust and transparency in communications on the topic [114]. This further emphasizes the need for continued international cooperation and coordination on using GenAI as an objective tool to enhance health communication.

Therefore, we also make a call to action for *international collaboration* to develop AI-related legislation that ensures global standards and practices respecting regional and national autonomies, with clear definition of high-risk applications in medicine and public health, and the *development of equitable ethical and regulatory guidelines and codes* to guide all sectors in the responsible use of AI in health care and public health that prioritizes health equity and human rights.

Conclusions

GenAI integration in health care and public health presents both significant opportunities and substantial risks, especially as it intersects with the complex dynamics of health information ecosystems. The main threats involve exacerbating information overload and disinformation and AI-generated misinformation exposure, all of which can negatively impact individual and collective health behaviors. However, through responsible, participatory, and evidence-based AI development, we can mitigate these risks and enhance the accuracy and accessibility of quality health information.

As emerging leaders in public health drawing on the experiences of professionals from diverse backgrounds across 5 continents, we recognize this dual nature of AI technologies. To harness GenAI's potential responsibly, we must prioritize AI literacy among health professionals and the public, integrate AI education into health curricula, and establish robust ethical guidelines and regulatory frameworks that promote equity and protect patient privacy. By taking proactive steps in education, research, and policy, we can leverage GenAI to enhance global health while safeguarding against its risks.

Acknowledgments

This paper used large language models (ChatGPT; OpenAI) with the purpose of improving the language. Large language models were not used for content development. In line with the "Best Practices for Using AI Tools as an Author, Peer Reviewer, or Editor," [115] the authors assert that they are aligned with the guiding principles of accountability, transparency, and confidentiality in what regards the use of AI tools.

Authors' Contributions

A Bandeira and TM developed the outline of the manuscript. A Bandeira, LHG, FH, JUS, MLG, RP, and SP equally contributed to the writing of the Viewpoint content, whereas A Berionni, TDP, and TM contributed with significant reviewing insights. All authors except for A Bandeira, A Berionni, TDP, and TM answered individually to the questions at the beginning of part 2; A Bandeira collected all answers and wrote a joint answer to each question that was later reviewed and approved by all authors. All authors reviewed and agreed to the final version of the manuscript.

Conflicts of Interest

TDP is an editorial board member for *JMIR Infodemiology*. TM, the editor-in-chief of *JMIR Infodemiology*, is a coauthor of this manuscript. To mitigate any potential conflict of interest, the authors clarify in the Authors' Contributions section that he did not participate in responding to part 2 questions or in the development of the core content of the manuscript. His contributions were limited to assisting with the development of the paper outline and providing final expert review based on his extensive subject matter expertise. The authors remain committed to maintaining transparency and adhering to the journal's policies regarding conflicts of interest.
