Abstract

Background: Health disparities persist and are influenced by digital transformation. Although digital tools offer opportunities, they can also exacerbate existing inequalities, a problem amplified by the COVID-19 pandemic and the related infodemic. Health equity audit (HEA) tools, such as those developed in the United Kingdom, provide a framework to assess equity but require adaptation for the digital context. Digital determinants of health (DDoH) are increasingly recognized as crucial factors influencing health outcomes in the digital era.

Objective: This editorial proposes an approach to extend HEA principles to create a specific framework, the digital health equity audit (DHEA), designed to systematically assess and address health inequities within the design, implementation, and evaluation of digital health technologies, with a focus on DDoH.

Methods: We propose a cyclical DHEA model based on existing HEA principles, integrating them with digital health equity frameworks. The DHEA cycle comprises six phases: (1) scoping the audit and mobilizing the team (including community members); (2) developing the digital health equity profile and identifying inequities (assessing DDoH at individual, interpersonal, community, and societal levels); (3) identifying high-impact actions to address DDoH and inequities; (4) prioritizing actions for maximum equity impact; (5) implementing and supporting change; and (6) evaluating progress and impact, and refining. This method emphasizes multilevel interventions and stakeholder engagement.

Results: The main result is the articulation of the DHEA framework: a structured, 6-phase cyclical model to guide organizations in the analysis and proactive mitigation of digital health–related disparities. The framework explicitly integrates the assessment of DDoH across multiple levels (individual, interpersonal, community, societal) and promotes the development of targeted interventions to ensure digital solutions promote equity.

Conclusions: The DHEA model offers an integrated approach to consider social, epidemiological, health, and technological variables, aiming to reduce health inequities through the conscious use of new technologies. It is emphasized that digital technologies can be the cause or the solution to inequalities; DHEAs are proposed as a tool to foster equity. Its systematic adoption, along with a collaborative approach (co-design) and trust building, can help ensure that the benefits of health digitization are equitably distributed while strengthening trust in institutions. Continued attention is needed to manage emerging challenges such as infodemiology in the era of big data and artificial intelligence.

(JMIR Infodemiology 2025;5:e75495) doi:10.2196/75495

Introduction

The concept of a health equity audit (HEA), as part of guidance issued by Public Health England (PHE) in the context of their Health Equity Assessment Tool, updated in May 2021, helps to articulate a clear framework to address health inequalities and has potential to be extended to the broader field of digital health [1]. Specifically, the PHE guidance defined how the objective of HEAs is to evaluate whether resources are distributed equitably with respect to the health needs of different population groups; they systematically examine health inequalities and access to services for particular groups or areas. Audits also ensure that actions to address health inequalities are incorporated into planning decisions, prioritizing actions to address health inequalities, and addressing how they can evaluate the impact of the actions on reducing inequalities.

These tools, despite having been widely used in the United Kingdom since the 2000s and subsequently neglected due to organizational changes in the British health care system, are currently recommended by PHE, which following the inequalities evidenced during the COVID-19 pandemic, renewed interest in adopting the tool for health care purposes; the tool could also be adapted for various applications of digital health technologies [2,3].

As the field of health disparities has matured to reach a crucial element of health care management and quality, we have simultaneously witnessed the effects of digital transformation on health status as well as health care [4-7]. This necessitates the need for a reexamination of the utility of HEAs in the design, implementation, and evaluation of digital health technologies. These inequalities have amplified during the COVID-19 pandemic, especially due to the misinformation caused by the infodemic, which pushed the World Health Organization to call a conference on the topic. Importantly, the convergence of factors such as volume and speed of information, misinformation, and disinformation flow, combined with political polarization, requires the forging of a community for the evidence-based practice of infodemic management [8].

Different Definitions of Digital Health

According to the National Institutes of Health, digital health refers to the use of information and communication technologies in medicine and other health professions to manage diseases and health risks and promote well-being [9]. For the European Union, digital health and care refers to tools and services that use information and communication technologies to improve the prevention, diagnosis, treatment, monitoring, and management of health-related problems, and to monitor and manage lifestyle habits that affect health. Digital health and care facilitates the use of emerging and innovative technologies, and has the potential to improve access and the quality of care, as well as increase the overall efficiency of the health care sector [10].

The World Health Organization [11] has three key objectives to promote the adoption and expansion of digital health and innovation:

1. Promote data sharing and support the implementation of digital solutions that contribute to informed decision-making
2. Improve knowledge through the best scientific communities
3. Assess and connect countries' needs with the supply of innovations

Access to digital technologies in health, including the internet, technological tools, digital agendas and systems, digital literacy, etc, has also become an increasingly important determinant of health and has a special relationship with social determinants of health. Emerging evidence from the scientific literature recognizes that access to digital technologies is now a determinant of health outcomes [12,13]. As digital determinants of health (DDoH) become increasingly recognized [14,15], a framework for digital health equity audits (DHEAs), including the evaluation of key DDoH, is needed.

Opportunities to Extend HEA Tools

In this editorial, we propose an approach to extend HEA tools to address shared international objectives of synergistically promoting both health equity and digital health adoption and access, framed as a DHEA. This strategy is rooted in the World Health Organization's objectives of equity and digitalization as described above and involves the synthesis of a tool that combines HEA concepts with stated goals of digital health equity, as published in other academic literature, and modeled based on proposals by the Agency for Healthcare Research and Quality in a comprehensive framework [16]. We support the implementation of a similar approach also focusing on improving the health status of the population in relation to the use of technologies and the context of health technology assessments. However, we must consider that new digital "approaches have the potential to address some of the structural challenges for marginalized populations.... Yet the digitalization of health care can also harm health equity if this digitally enabled ecosystem moves forward without proactive engagement, planning, and implementation" [5]. As discussed in the recent literature, the evidence linking inequality in health care to misinformation exposure and mitigating strategies is a complex area where further research is needed [17-19].

The DHEA Cycle

Overview

Building upon standard HEA principles, the DHEA cycle integrates the Framework for Digital Health Equity to specifically address how digital technologies impact health disparities. It emphasizes understanding and acting on DDoH across multiple levels (individual, interpersonal, community, societal) to ensure digital health solutions promote equity rather than widen gaps.

The DHEA cycle phases are shown in Figure 1.

XSL•FO
RenderX

Figure 1. Digital health equity audit (DHEA).

Scope the Audit and Mobilize the Team (Phase 1)

Action

A diverse working group is formed including community members (especially from disparity populations), clinicians, IT specialists, designers, policy makers, and public health professionals.

Integration

The specific digital health tool, service, or system being audited (eg, a new patient portal feature, a telehealth service) is defined. Priority populations and potential equity concerns are agreed on, explicitly considering the Framework for Digital Health Equity [15] and its emphasis on populations adversely affected by health differences (racial/ethnic minorities, those with low-income, those who live in rural areas, sexual and gender minorities, or individuals with disabilities).

Example

When auditing a new telehealth platform for primary care, the team can include patient representatives from low-income neighborhoods, accessibility experts, primary care physicians, and IT developers, prioritizing equitable access and usability for seniors and nonnative speakers.

Develop the Digital Health Equity Profile and Identify Inequities (Phase 2)

Action

Data is gathered to create a profile of the target population's interaction with the specific digital health tool/service and the broader digital environment, using surveys, interviews, use data, population health data, and community assessments.

Integration

This profile must assess relevant DDoH across the four levels:

XSL•FO
RenderX

- Individual: digital literacy, technology access (device/internet), digital self-efficacy, attitudes/trust toward technology
- Interpersonal: implicit technology bias from providers, patient-provider communication via digital tools, family/caregiver technology interdependence
- Community: broadband availability/affordability, local technology support resources (libraries, community centers), health care system's digital infrastructure quality, relevant community technology norms
- Societal: technology policies (reimbursement, privacy), data/design standards (accessibility, language), algorithmic bias, social norms around technology

Action Continued

The profile is analyzed to pinpoint specific inequities—where are there avoidable unfair differences in digital access, use, experience, or outcomes between population groups?

Example

The profile for the telehealth platform reveals that seniors have lower adoption rates. An analysis identifies key DDoH barriers: lower digital literacy and lack of affordable broadband (individual/community), coupled with clinician assumptions about seniors' ability/interest (interpersonal implicit technology bias). An inequity is identified: seniors face avoidable barriers to accessing telehealth compared to younger higher-income groups.

Identify High-Impact Actions to Address DDoH and Inequities (Phase 3)

Action

Potential interventions are suggested to address the specific DDoH barriers and inequities identified in phase 2, reviewing the evidence for effective strategies.

Integration

The focus is on developing multilevel interventions that target "upstream" determinants (community and societal levels) where possible, as these often have a broader and more sustainable impact on equity, as highlighted by the summarized text. Actions addressing individual skills, interpersonal interactions, community resources, and systemic policies/design should be considered.

Example

The following actions can be taken to address the telehealth inequity:

- Individual: offer digital literacy training tailored for seniors; provide loaner tablets
- Interpersonal: train clinicians on identifying and mitigating implicit technology bias
- Community: partner with local libraries or senior centers for technology support hubs; advocate for expanded community broadband initiatives
- Societal: Advocate for policies ensuring telehealth platforms meet high accessibility standards (Web Content Accessibility Guidelines)

Prioritize Actions for Maximum Equity Impact (Phase 4)

Action

The potential actions are evaluated based on criteria such as potential impact on reducing the identified inequity, feasibility, cost, community acceptability, and alignment with organizational goals.

Integration

Actions most likely to address root causes (upstream DDoH) and benefit populations disproportionately are prioritized, ensuring the prioritization process involves stakeholders, especially from affected communities.

Example

Partnering with senior centers for training/support (community/individual: high impact, feasible) and advocating for better broadband (community/societal: high upstream impact, longer term) can be prioritized over simply providing tablets without support (individual: less sustainable).

Implement and Support Change (Phase 5)

Action

An implementation plan is developed, allocating necessary resources (funding, staffing, partnerships) and executing the prioritized actions.

Integration

Resources need to specifically address the DDoH barriers (eg, funding for digital navigators, accessible design implementation, community infrastructure partnerships). Synergy needs to be fostered between the implementation team, decision makers, and the target community through ongoing communication and feedback loops, adapting based on initial rollout experiences.

Example

The following actions can be taken during this phase: secure funding for trainers at senior centers, deploy accessible platform updates, launch clinician training modules, or establish a feedback channel with senior users.

Evaluate Progress and Impact, and Refine (Phase 6)

Action

The implementation process is monitored, and the impact of the actions is evaluated against the initial objectives and the identified inequities.

Integration

Specific, measurable indicators are defined that track changes in DDoH (eg, digital literacy scores, broadband access rates, device ownership) and health equity outcomes related to the digital tool (eg, telehealth use rates stratified by age/income/race, patient satisfaction scores by demographic group, changes in relevant health metrics for disparity groups). Evaluation findings need to be used to refine actions, inform future DHEA cycles, and demonstrate accountability.

XSL•FO
RenderX

Example

Telehealth appointment completion rates can be tracked to analyze seniors versus other groups, pre- and postscores for the digital literacy assessment for participants, qualitative feedback on usability, and number of broadband sign-ups through advocacy efforts. If senior use remains low, phases 2 and 3 can be revisited to identify potentially missed DDoH barriers.

Conclusions

The DHEA model is an integrated model that takes into account social, epidemiological, health, and technological variables. The integration of knowledge and resources, together with the involvement at the institutional and the population levels, should produce a health gain for the majority of the population, reducing health inequities thanks to new technologies and strengthening trust in government institutions and health care. The systematic adoption of integrated and digitized tools for reading the system could certainly contribute to the evaluation of the effectiveness of interventions [20]. However, the digitization of health services in 2025 is increasingly important and its massive implementation is expected in the following years. The large amount of data that we will have to manage—fueled by the continuous flow of information—is converging and will converge with artificial intelligence all over the world, leading to a rapid and proportionally difficult-to-control diffusion of infodemiology. The increased convenience, accessibility, and penetration of internet services have significantly transformed how people obtain information on health-related issues. The rapid proliferation of information and communication technology tools has led to an era of unprecedented accessibility to vast repositories of information, especially through online communication channels and social media platforms [21]. In summary, we could therefore affirm that new technologies can be the cause of inequalities or the solution to health inequalities. We would like the DHEA tool to help increase equity at all levels so that one day everyone can benefit from the advantages of technologies and, through them, be in control of their health and well-being. Facilitators include building trust (eg, providing evidence for health messages), while barriers include user reluctance to accept support. The main recommendations are adopting a collaborative working approach (involving users, developers, health care professionals, policy makers, etc, often through co-design) and using effective advertising to raise awareness of available support.

Being aware of the great advantages of the widespread, adequate, and fair use of continuous technological and digital innovations available to science, we must never forget that they are the tool and not the goal.

Conflicts of Interest

Abstract

Background: With the advances in digital information sharing channels, democratization of content, and access, as well as social shifts in information exchange, we live in increasingly complex information environments. How people process and manage this is layered with multiple determinants that can impact information seeking, health behaviors, and public health. Understanding the dynamics of the information environment in priority populations and its impact on communities and individuals is critical for those working in public health and health emergencies.

Objective: This study aimed to provide an overview of the approaches to and implementation of information environment assessments as they relate to public health and health emergencies.

Methods: We conducted a rapid scoping review of the approaches to, and implementation of information environment assessments. The search followed guidance from the Joanna Briggs Institute on conducting systematic scoping reviews, and our reporting is in line with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for scoping reviews. We included both academic and gray literature in the English language. As this is an emerging field, an additional step involved input from an informal expert group to identify any further tools or approaches. Studies that assessed, described, or discussed approaches to assessing the information environment were included. We excluded papers where the information environment was not the primary focus, or the focus was on individual components only. Two authors (BKW and SVM) independently screened results for inclusion.

Results: A total of 17 publications were identified through the structured literature and internet searches, with an additional 5 sourced from the informal expert group. The review highlighted a significant variety in the breadth and number of domains covered in an assessment, including information needs, seeking, access, production, engagement, information quality, and reach. Some assessments adopted a comprehensive, systems-oriented approach, examining factors influencing information beyond the individual level to encompass broader systemic dynamics, while others were significantly narrower in scope.

Conclusions: The COVID-19 pandemic has intensified interest in understanding how the information environment shapes people's access to, engagement with, and ability to act on health information. Assessing the information environment is a critical step in identifying and understanding barriers and facilitators that impact different populations and identifying opportunities for strengthening systems. However, a universally accepted approach for such assessments in public health and health emergencies is currently lacking. This paper contributes to the literature by synthesizing current knowledge on assessment tools and frameworks, providing a foundation for future research and development in this area.

Introduction

With the advances in, and increasing access to digital information sharing channels, democratization of content, and social shifts with high levels of connectivity [1], we live in increasingly complex information environments. Information environments are determinants of health, directly impacting health decision-making and also indirectly affecting health by informing people's choices about other health determinants [2]. In any given day, a person can be exposed to health information through various social media channels, from family and friends, from colleagues, in their workplace, through advertising, through media, and from health care workers—all delivered, amplified, and shared through different platforms, modes, and volumes. Factors in an information environment may also contribute to reducing an individual's exposure and access to health information, also impacting their ability to effectively process and manage health information and make informed decisions. The dynamics shaping the information environment are broad and include structural, organizational, community, and individual factors. Navigating this is layered with multiple determinants such as social and commercial determinants of health.

During a health emergency, health information seeking, exchange, and engagement can be heightened, creating an infodemic. This can make it hard for people to find the information they need, in formats they trust, from locally relevant and appropriate sources. An infodemic is the overabundance of information, accurate and otherwise, in the physical and digital space that accompanies an acute health event [3]. The impact of infodemics on public health has been extensively documented [4-7], yet methods to prevent, assess, and identify early opportunities to mitigate the impact are less well-defined. Understanding the information environment in a priority population is important for those working on public health and health emergencies. It can provide valuable insights to guide risk communication, community engagement, and infodemic management activities, as well as a broader range of public health initiatives and system strengthening. The World Health Organization (WHO) framework for "Strengthening the global architecture for health emergency prevention, preparedness, response, and resilience" has community protection as a core pillar [8]. Initiatives that support assessing the Information environment are a key component in informing strategies to promote and support community resilience.

Mapping the multiple factors impacting an individual's experience in accessing, processing, and engaging with information has been described in several different ways in the literature. There is significant disparity in comprehensiveness between labels and accompanying tools defining the scope. In the literature, the terms "information environment" and "information ecosystem" have been used interchangeably. The Carnegie Endowment for International Peace defines an information environment as "The space where human cognition, technology, and content converge" [9]. Internews, a global media support nonprofit, uses the term information ecosystem and defines it as, "The combination of information providers, channels, platforms and tools that people have at their disposal to access, share and create information. Internews Information Ecosystem Framework maps the available information supply, demand and the complex relationships between the different actors, to make it easier to understand and improve the overall quality of information available in a specific community" [10]. And Radsch [11] states, "A healthy information ecosystem is a well-balanced and diverse system where information is created, shared, and used responsibly."

In a public health context, the WHO has defined an information environment as "The entire universe of information that individuals, communities, health systems, and societies inhabit. This constitutes structures, agents, and systems that influence information seeking, access, sharing, and use. In an infodemic management context, the information environment is overlayed with the considerations of the quality of the health information content and sources, because this affects how the information environment affects people's adherence to health guidance and health behaviors" [12]. This is different from an information ecosystem that is posited to be "more specific to a community that has norms and structures for how information is shared, reacted to and acted on" [12]. For the purposes of this research, we use this definition of information environment, noting that there is not established consensus on these definitions among scholars. Table 1 summarizes the differences between the 2 terms as per this definition. This paper seeks to understand the different approaches to information environment assessments and the domains that are included. It is intended to provide an overview of the current literature, identify strengths and weaknesses in current approaches, and be used to inform the development of comprehensive assessments.

XSL•FO
RenderX

Table . Comparison of terms, information environment, and information ecosystem.

Term	Information environment	Information ecosystem
Definition	The entire universe of information individuals, communities, health systems, and societies inhabit.	More specific to a particular community and its norms and structures for how information is shared, reacted to, and acted on.
Scope	Broader; it includes structures, agents, systems, and processes.	More focused; centers on a specific community and how the community engages with information.
Key components	Structures, agents, and systems influencing information seeking, access, sharing, and use.	Norms, rules, and established practices within a community that govern information sharing and responses.
Application	Applies to large-scale settings (eg, societies, health systems) with an emphasis on access, engagement, and use of information.	Applies within specific communities, emphasizing norms and practices of that group.
Infodemic management context	Concerned with quality and accessibility of health information and how these influence health-related behaviors and adherence to public health guidance.	More relevant to community-level behaviors and practices concerning health information.
Influence on behavior	Affects society-wide adherence to public health guidance and behaviors.	Shapes community-specific responses to shared information.
Example	Global or national health information systems, media landscapes, social media platforms, and their interaction with public health.	Local health organizations, community groups, and small closed social networks (eg, WhatsApp or Viber groups) with established norms.
Assessment	Comprehensive, aiming to evaluate the strength of systems that influence information production, dissemination, and use.	Focused on how specific communities react to, use, and share information.

Methods

Overview

We conducted a rapid scoping review of the approaches to, and implementation of, information environment assessments as they relate to public health. We followed guidance from the Joanna Briggs Institute on conducting systematic scoping reviews [13] and our reporting is in line with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for scoping reviews [14] (Checklist 1). We included both academic and gray literature. As this is an emerging field, an additional step involving input from an informal expert group to identify any further tools or approaches is needed. Experts were invited to participate in the informal group due to their current activities in, and knowledge of, the information environment space.

Review Objective

This study aimed to provide an overview of the approaches to, and implementation of information environment assessments as they relate to public health.

Review Questions

We aimed to seek answers to the following research questions. First, what research questions and phenomena of interest do researchers and practitioners intend to address when assessing information environments? Second, what approaches to defining and assessing information environment have been outlined and implemented? And finally, what domains are covered and how are they assessed?

Search Strategy

The search strategy included both academic and gray literature. To source unpublished literature, including government reports and news articles, the Google search engine was used. Search terms were adapted, and the first 100 results were scanned in each search. The search strategy for academic literature was developed in line with MEDLINE and then adapted for other databases. We initially trialed the search with MEDLINE, testing for keywords. Other databases included in the search include ACM Digital Library, EBSCO, and Embase. The search was carried out in June 2024.

Search Terms

As our rapid review was focused on understanding the different definitions and assessments associated with information environments, our search terms were developed to focus on the core concepts of the information environment (“information ecosystem” OR “information environment” OR “information landscape”) and the assessment component (assessment OR mapping OR analysis OR tool OR scan). These were initially tested in MEDLINE and revised with the initial searching results. We limited search results to the past 10 years (2014-2025). An adapted search was used for Google.

Inclusion and Exclusion Criteria

We included studies, reports, or documents that assess, describe, or discuss approaches to assessing the information environment in the English language. There was no geographical restriction. As the aim was to map the existing tools and approaches across published and unpublished literature, we included reports, perspective and discussion papers, and government and NGO

XSL•FO
RenderX

documents, including reports and presentations, as well as academic publications.

We excluded papers where the discussion of assessing an information environment was not the primary focus or where it contained insufficient relevant content. We excluded any papers that referred only to individual components of the information environment, for example, those looking just at algorithms, social media, or image analysis. While we did include papers reporting on information environment assessments outside of the domain of health (such as military, communication, and so on), those hyperfocused on specific and narrow circumstances, that is, the corporate setting of an educational facility, or where the "information landscape" was defined only as an audit of digital products, were excluded. For the Google search, we were looking for reports or publications by organizations or professional bodies that described approaches to assessing the information environment.

Study Selection

The selection of articles was defined by the inclusion and exclusion criteria. In line with the iterative nature of scoping reviews, these criteria were reviewed as the search progressed. The Rayyan platform was used for deduplication and screening. Two investigators (BKW and SVM) independently screened article titles and abstracts, excluding irrelevant studies. The full text was reviewed for articles deemed possibly relevant, or where inclusion was difficult to ascertain from the title and abstract. Any discrepancies were resolved via discussion.

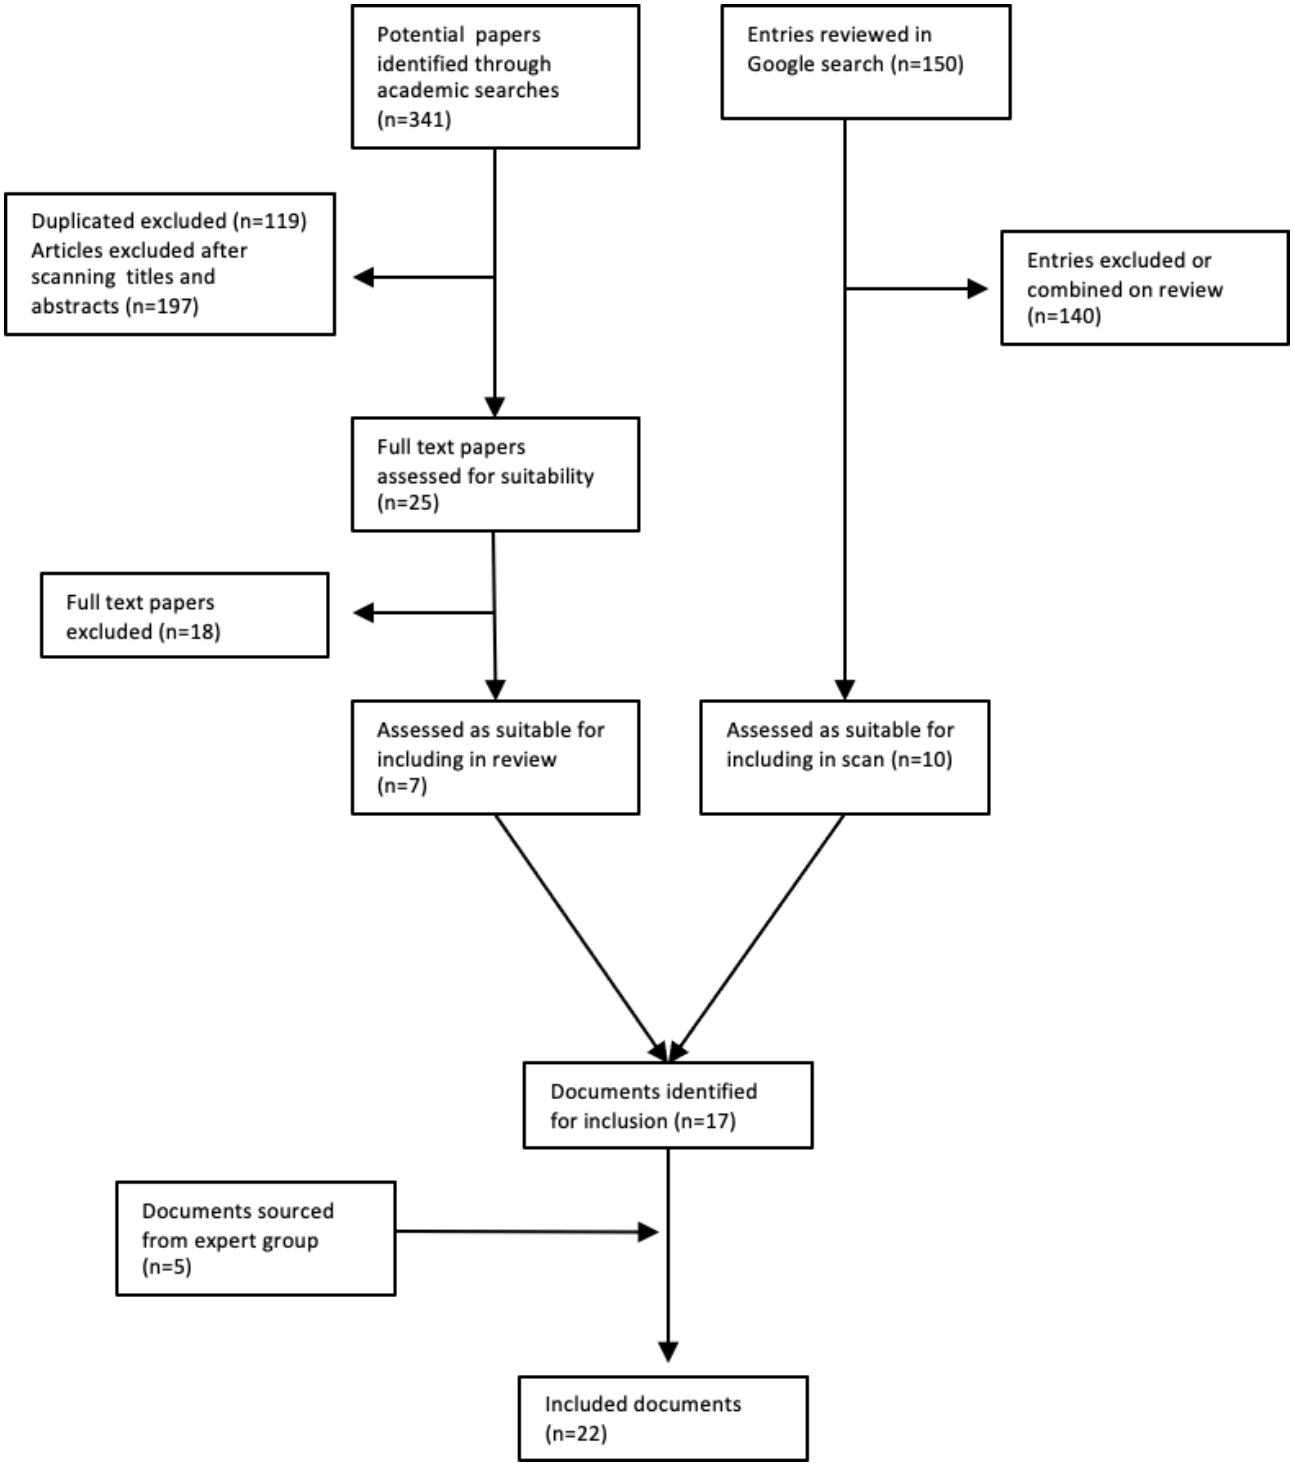
In the Google search, where multiple returns pointed to the same organizational approach or methodology (eg, there were several Internews reports returned that followed similar methods), we combined them into 1 entry.

Expert Input

A virtual meeting was held with an informal group of experts providing an opportunity for identification of any further tools and assessments. These experts were primarily practitioners working in the information environment space and were from a diverse range of countries and organizations. Experts were invited to participate in the informal group due to their current activities in, and knowledge of, the information environment space. Publications were provided to the research team and included after the literature assessment where there was a publicly available version.

Summarizing and Reporting

The data charting method was trialed with the first 3 papers and revised. Data were collected regarding study characteristics, area of focus and publication intent, domains covered and data collection for assessment method.



Results

Overview

A total of 17 publications were identified for inclusion through the structured literature and online searches, and an additional 5 were identified through the expert group. Figure 1 illustrates the study selection process. While we did exclude publications that were overly narrow in their scope (eg, only including social media), we did include those that used a single data collection point (ie, interviews) to measure multiple domains. The selected papers focused on health and emergencies, as well as other areas, such as education, defense, and corporate settings. Where we identified multiple reports using the same methodology from an organization, we combined them into one entry. An example of this is Internews [15], which conducted and published assessments in several geographical settings, as well as the CDAC (Communicating with Disaster Affected Communities) Network [16]. Table 2 describes the characteristics of the included publications, and findings are summarized here. The use of "information ecosystem" or "information environment" in this table reflects the preference of the paper's authors, while the definitions used in the core paper are as explained earlier.

Table . Characteristics of included publications.

Information	Intent or aim	Focus area	Domains	Data use	Notes on approach
Ye and Yang [17] (conference paper)	To provide theoretical guidance for the governance of university network public opinion.	University network public opinion information ecosystem.	Information (quality, type, quantity, security, authenticity, and timeliness), information subject (communication ability, attitude tendency, user situation, and platform function), and information environment (technical, cultural, physical, economic, and institutional and science environment).	—[a]	Proposes analytic hierarchy process to combine qualitative and quantitative data.
Savoia et al [18] (journal article)	To articulate a conceptual framework in support of evaluation activities in emergency risk communications.	Emergency risk communications evaluation framework.	Information environment level: timeliness, news coverage, message content (literacy, framing, transparency, self-efficacy, consistency, and rumors).	—	Proposes information environment as a component of emergency risk communication framework.
Moldovan-Johnson et al [19] (journal article)	To describe and assess how patients with cancer navigate the information environment with regard to their illness.	Information environment of patients with cancer.	Active information seeking, exchange, and engagement with different data sources including digital and community. Media and health care workers.	Literature review, expert consultation, repeated surveys with patients.	Information environment assessment focuses on information seeking and engagement.
Ramírez et al [20] (journal article)	To identify and critically evaluate public sources of information about the causes and controllability of air pollution and its health effects, and potential disparities in information reach and utility.	Environmental health.	Information sources: public, expert, and media; information quality: breadth, depth, and type; and information reach: vulnerable groups, access to technology, and language.	Analysis of existing communicators and communication strategies, interviews with stakeholders, and community residents.	Focus on environmental risk communication. Findings show themes around information quality, sources, and reach.
Estrada et al [21] (journal article)	To describe a participatory multilevel, ecological information inequity intervention in a rural, majority-Latino community.	Rural, Latino community in the United States.	Informational (where health information can be provided), conversational (where residents feel comfortable discussing health issues), and connection (where a relationship exists).	Communication asset mapping: Workshops and interviews with organizations and residents.	Describes a participatory health communication asset mapping research process tailored for rural community.
El Tímpano [22] (NGO[b] report)	To learn what issues are most important to Latino immigrants and what gaps and opportunities exist in connecting them to the news and information they need to be informed and engaged.	Migrant communities.	Structural: health, housing, and safety. Information: access, language, and understandability.	Desktop research, surveys, community conversations, outreach, and immersion.	Community-based assessment conducted by people with significant ties to the local community.
Mazumdar et al [23] (journal article)	To highlight the interconnectedness of different actors in the agricultural communities and the complexities involved in establishing trust of information.	Rural agricultural communities.	Information needs, sources, processes, social context, and knowledge. Skills and knowledge. Use of technology.	Field visits, interviews, focus groups.	The paper includes exploration of different social contexts and power dynamics in the information landscape in rural areas.

XSL•FO
RenderX

Information	Intent or aim	Focus area	Domains	Data use	Notes on approach
Internews [15] (NGO report)	To identify how information flows through communities.	Humanitarian settings, emergency response, and vulnerable communities.	Information needs, information landscape, production and movement of information, dynamic of access, use of information, impact of information, social trust, and influencers in the community.	Interviews with health system stakeholders, media organizations, population and humanitarian organizations.	Broad assessment model across 7 domains. Applied to different settings (including as Listening Post Collective in the United States) such as Columbia, Thailand, and California.
Wanless and Shapiro [9] (report)	To define and understand the conditions within the information environment that can foster democratic societies and encourage active citizen participation.	Global.	Human cognition, technology, and content. Information processing, social norms, access, and platforms.	Social media, political data, education levels, access to technology, press freedom, perception and trust data, media consumption data, and policy and legal data.	The paper proposes how the CERN (European Center for Nuclear Research) model can be used for studying the information environment.
Radsch [11] (network collective report)	To map the multidimensional aspects of an information ecosystem that can be used at various levels of analysis.	Global.	ICT[c] infrastructure (platforms, penetration, resource allocation, commercial impacts, and content moderation), dynamic conditions (access and connectivity, data and digitalization, media system, new media, transparency and accountability, and anchor institutes and keystone species).	—	Proposes model with multiple domains across different levels of analysis.
GAO[d] [24] (government report)	To better inform officials on the use and protection of the information environment including effects on government department mission, threat actors, threat actions, institutional challenges, and emerging technologies.	US National security.	Cognitive dimension: beliefs, norms, vulnerabilities, motivations, emotions, experiences, morals, education, mental health, identities, and ideologies. Physical dimension: human beings, command and control facilities, newspapers, books, communication towers, computer servers, laptops, smart phones, and tablets. Informational dimension: collection, processing, storage, dissemination, and protection of information.	Questionnaires to defense organizations, interviews, and desktop review.	Identifies 3 broad dimensions of the information environment – cognitive (human-centric), informational (data-centric), and physical (tangible and real-world).
RAND [25] (research institute report)	To harness the power of information to increase efficiencies, improve security, and deny access and advantages to adversaries.	US National security.	Information operations; social media; data analytics and big data; intelligence collection and analysis; and information security, privacy, and information-sharing.	—	Bibliography of operational reports in the information environment. Most focused on Dept of defense efforts.

XSL•FO
RenderX

Information	Intent or aim	Focus area	Domains	Data use	Notes on approach
Röttger and Vedres [26] (academic report)	To describe and understand research on the information environment and effects on individuals and groups.	Research.	Exposure characterizes (encounters between individuals and information content). Engagement (interaction between the individual and the information they are exposed to). Digital technologies (including information generation, seeking, and sharing).	—	Interdisciplinary literature review identifies various components.
NATO[e] Strategic Communications Centre of Excellence [27] (simulation platform)	To meet training needs of defense sector for understanding the information environment.	US National security.	Information environment infrastructure (networks), dynamics (processes), and audiences (behavior, opinions, and characteristics).	Simulated platform for training purposes.	Aims to provide dynamic training opportunities through an AI-generated simulation platform across the information environment.
CDAC Network [16] (NGO report)	To provide responders with the evidence needed to adapt and expand their communication, community engagement, and accountability efforts.	Humanitarian settings.	Information needs, media landscape, preferred channels, information sources and verification mechanisms, information access, trust, population, and worker perspectives.	Document review, focus groups, key informant interviews.	Assessment methodology applied to different settings such as Syria and Türkiye.
UNHCR[f] [28] (report)	To identify the information and communication needs of refugees and migrants, as well as the most appropriate channels for information sharing.	Refugees and migrants.	Information needs, channels used, barriers to access, and reliable information sources.	Semistructured interviews.	Assessment focused on information needs and barriers and facilitators in a transit center in North Macedonia.
Canadian Digital Media Research Network [29] (technical report)	To enhance collective understanding of the stable and dynamic dimensions of the Canadian information ecosystem, articulate its vulnerabilities, and characterize current and emerging information threats.	As the Canadian information environment relates to politics, media, and state of democracy.	Vulnerabilities: inequity, toxicity, polarization and insularity, and trust. Threats: misinformation and foreign influence. Engagement: trends in news appetite and online engagement with politicians.	Digital trace data (social media), opinion tracking (monthly surveys), media monitoring.	Monthly assessment reports, first on May 2024.
Fleisher [30] (book chapter)	To describe an environmental scanning process to support corporate strategic decision-making.	Corporate settings.	Institutions: including policy, government, regulatory agencies, and legislation. Stakeholders: key actors that can influence policy. Arenas: (platforms, media, and elections). Issues: (gaps or controversy between stakeholders and actions or behaviors). Processes: (legal processes, judicial bodies).	—	Information on setting up an organizational focused process.

XSL•FO
RenderX

Information	Intent or aim	Focus area	Domains	Data use	Notes on approach
Bridgman et al [31] (book)	To describe the relationship between digital media and democracy by investigating elements of the Canadian information ecosystem.	Canada digital ecosystem.	Digital media focus. Concentration of influence and fragmentation.	Social media data and survey data	Discussion on Canadian information environments and assessments by "Media ecosystem observatory" as part of Canadian Digital Media Research Network.
Ahmad [32] (report)	To identify the various information ecosystems in place among the youths in Malaysia.	Malaysian youth.	Media consumption, media ownership, community access, information and media sustainability, opportunities and needs assessment.	Survey and focus groups.	Assessment and methods by Center for Independent Journalism, supported by Internews.
USAID[g] [33] (toolkits and reports)	To describe an assessment process for the digital ecosystem.	Global.	Framework includes digital economy (trade, e-commerce, financial services, talent pool, and startups), digital infrastructure and adoption (connectivity, security literacy, divide, and affordability), digital society, rights and governance (rights, governance, government, civil society, and media), and cross-cutting (inclusion, cybersecurity, emerging technology, and geopolitical positioning).	Desk research, interviews.	Includes assessment toolkit, factsheets, framework, templates, and country assessment examples.
IPIE[h] [34] (report)	To understand how technology experts perceive the varied features of, and threats to, the information environment in their countries of expertise.	Global.	Top 5 features of healthy information environments: availability of accurate information, diversity, literacy, technical infrastructure, and accountability. Information threat actors: politicians, social media platforms, and governments.	Survey of scientists.	Global survey on information environment components conducted in English, Arabic, Chinese, French, and Spanish.

[f]UNHCR: United Nations High Commissioner for Refugees.

[g]USAID: United States Agency for International Development.

[h]IPIE: International Panel on the Information Environment.

Focus Area and Population Groups

The focus of the publications differed from universally applicable models or approaches, sometimes repeated in different settings, to those developed for, or conducted with, specific communities. Of the total, 3 of the publications focused on national security, with all 3 having a United States focus [24,25,27]. Of those that described assessments designed with specific communities or settings in mind, focus areas included a university network [17], patients with cancer [19], corporate settings [30], environmental health [20], a rural Latino community in the United States [21], a migrant community in the United States [22], rural agricultural communities in Bangladesh [23], Malaysian youth [32], and the Canadian digital ecosystem [29,31]. International organizations described a focus on humanitarian settings and emergency response in a range of countries such as Colombia, Syria, North Macedonia, and Türkiye [15,16,28,33].

XSL•FO
RenderX

Domains Covered

There was a wide approach to the breadth and number of domains covered. Some publications focused on information needs, seeking, access, production, and engagement [18,19,21,22,26,28], while others included indicators on information quality and reach [17,20]. Some publications focused primarily on media, including media consumption and ownership, community engagement, and access [16,32], while others were focused on the digital environment only [31,33]. Most described domains in a neutral manner; however, 2 publications specifically sought to identify "threat actors" or "threats" to the information environment [16,34]. Several publications discussed frameworks or approaches to an information environment assessment that were comprehensive and broad, including factors that look beyond the individual focus to take a systems approach to influencing factors. These included the model proposed by Radsch [11] that emphasized the interconnectedness of different institutions, systems, and sectors. Another example is Fleisher [30] who considered wider arenas, such as elections and media, as well as legal and judicial processes. Trust as a specific domain was evident in 3 publications [15,16,29].

Operational Publications and Tools

Publications included in the review were a mix of proposed models with indicators, research projects, and operational tools. In total, 12 publications described assessments that had been completed. Both Internews and CDAC Network have multiple assessments using similar methods that have been used in several different settings globally. For Internews, this includes Colombia, Thailand, and California [15], while the CDAC network had conducted assessments in countries such as Syria and Türkiye [16]. In 2024, a new technical report was introduced in Canada, issuing monthly Information Ecosystem Situation reports [29]. The United States Agency for International Development Digital Ecosystem Country Assessment has accompanying documents such as a toolkit, templates, framework, and research guide [33]. Most operational tools included a combination of desk research, digital indicators, and community or stakeholder input in the form of interviews or a survey.

Discussion

Principal Findings

This paper outlines the current landscape of both academic and gray literature focused on approaches to assessing and understanding the information environments in which we live. Since 2020, the importance of the information environment in public health has grown significantly with the COVID-19 pandemic underscoring how a poor information environment can hinder people's access to accurate, reliable, and appropriate information. In response, a wide range of methods, tools, research, theory, and practices have emerged [35]. Understanding the dynamics of an information environment is vital in identifying barriers and facilitators and helping to inform action. This could include informing risk communication, community engagement, and infodemic management interventions, as well as providing guidance for policy, health service access, health system strengthening, and health literacy interventions, among others. With this in mind, and to acknowledge the delay that can occur in publishing academic literature, we structured this review to look beyond published papers and incorporate reports, methods, tools, and documents sourced through an internet Google search, and through the input of experts working in the field.

We found significant variation in the domains considered to constitute the information environment and how they were assessed, as well as variation in terminology and how they were described. This presented challenges in comparisons between approaches. Many papers looked at information production, but only a few included consideration of exposure, amplification structures, and consumption. The intention and breadth of scope in each example were different, which guided the individual approaches. Some focused on media environments only and did not include wider health system determinants or consider them only in an emergency context and not in routine work. Few considered the breadth of domains included in the WHO definition of an information environment, such as the structures, agents, and systems that influence information seeking, access, sharing, and use. The model described by Radsch (2022) [11] considered multidimensional aspects across a broad number of domains, such as commercial impacts, platforms, and policy, but there was no description of how this could be implemented. Community-level assessments reported benefit in building on community networks, strengths, and existing relationships [21-23].

While the literature has been maturing, health and humanitarian emergencies, including the COVID-19 pandemic, have highlighted the need for practical, implementable solutions to understand and assess infodemics and information environments for those working on the ground [36,37]. Some of the most comprehensive models in this review were those that had been developed by international nongovernment organizations (NGOs) and deployed in the field. Internews has conducted a number of information environment assessments across a range of settings, including supporting other organizations in their work [15]. Their work has been evolving over time in humanitarian and emergency situations. The CDAC Network has also applied its method to assessments in countries such as Syria and Türkiye [16]. The United States Agency for International Development Digital Ecosystem Country Assessment model included factors such as cybersecurity, geopolitical positioning, and affordability, alongside literacy and media [33]. Interestingly, trust was mentioned as a specific domain in 3 documents we assessed, all of them global operational documents [15,16,29].

How we as individuals navigate our information environment can change daily and is influenced by a range of factors, including the health of ourselves and our families, and the attitudes of a health care worker delivering the information. It is also influenced by things out of an individual's control, such as the availability of information in relevant languages, market factors, trust in institutions and community, commercial and social determinants of health, the regulatory environment, and the media landscape. While individual social determinants of health, such as access to education and social and neighborhood

XSL•FO
RenderX

environments, can impact how individuals navigate the information environment, the broad-ranging impact has led to calls for information environments to be included as an element in social determinants of health models [2].

It has been noted that assessing the information environment is incredibly complex [3]. While we can ask about and ascertain the media that people are exposed to, developing ways to measure the engagement with it over time, the change in consumption and individual processing patterns driven by emotional state, the interaction between media consumption and offline interactions, and conversations remain very challenging. In a similar vein, identifying and defining health system policy, commercial influences, and ethical practices is one thing, but understanding their impact on each other, and on the information environment as a whole, is another. Here, scholars and practitioners can face challenges similar to those who are studying social network analysis in terms of defining and measuring ties and impacts between and within factors over time [38]. As an information environment or ecosystem can change rapidly, particularly in emergency situations, another challenge for assessment tools is likely to be how changes to, and impacts both on and within environments and communities can be measured over time while remaining flexible enough to incorporate changes and the evolution of factors. Here, there may be opportunities to build on systems thinking models that seek to understand interrelationships between complex components in relation to a common purpose [39].

The publications reviewed for inclusion in this paper revealed a gap between the literature and the tools and documents being produced for use in the field and by international organizations to operationalize work rapidly. This could be due to the publishing delay, with time taken for papers to be processed through the peer-review process, but it could also suggest a wider divergence between research and practice. This has been reflected in another recent paper, with the authors noting the diversity of factors needing consideration in an information environment and issuing an urgent call for information scientists to design and guide the development of systems [37]. As these processes and frameworks continue to mature, more targeted collaborative research and partnerships between academia and practitioners are needed to ensure approaches employed on the ground are evidence-based, inform best practice, and that practitioners are supported to document their work and assess relevance and transferability across settings. There is a need for robust models that are comprehensive and based on the best global evidence and practice, as well as the need for them to remain agile to respond to the ever-changing conditions and factors impacting an information environment. In addition, more evidence is needed to understand how we can translate research on these complex interactions into a workable assessment that can be used by national and subnational organizations to inform their work in a way that is rapid, cost-effective, and comprehensive.

Strengths and Limitations

Due to the rapid nature of the review, decisions were made to narrow the scope, which introduced limitations. The first of these is the inclusion of English-language articles only. This limited the breadth of the findings, and it would be valuable to include languages other than English in future research. Although limited to the English language only, the papers included here cover different geographical and cultural contexts.

As our rapid review was focused on understanding the different definitions and assessments associated with information environments, our search terms were confined to those specifically related to reporting on information environments. This narrowed the findings. The terminology in this space is not consistent, and there have been precursor terms. For example, in political and communication science, some researchers have used “media landscape” or “media ecosystem” as broadcast media was the primary contributor to what we now call an information environment. Our search limited findings by not exploring the different ways assessments such as this may have been defined and described previously (eg, “media ecosystems”). In addition, considering the broad nature of the work, many of the findings focused on external factors, rather than individual processing and theory of human interactions with the information environment. The inclusion of assessments beyond the realm of those specifically focused on health was a strength that enabled a broader view.

Conclusion

The COVID-19 pandemic has intensified interest in understanding how the information environment shapes people’s access to, engagement with, and ability to act on health information. Assessing the information environment is a critical step in identifying and understanding barriers and facilitators that impact different populations. However, a universally accepted approach for such assessment is currently lacking. This paper contributes to the literature by synthesizing current assessment tools and frameworks, providing a foundation for future research and development in this area. It aimed to answer questions about approaches to, and the intent of, information environment assessments and the domains covered. Findings showed significant variation, including in the domains considered to constitute the information environment. The reported gaps between research and practice reveal a need for more collaborative projects. Increasing understanding of what constitutes a healthy information environment and the factors that impact this, in both a positive and negative way, can help to ensure individuals and communities are best placed to receive, understand, and act on good accurate health information, to better protect public health, build trust, and improve health outcomes. As the impact of information environments on public health outcomes continues to grow, there is a need for comprehensive tools that can be deployed in a rapid manner, with practical applicability.

Abstract

Background: Digital media memes have emerged as influential tools in health communication, particularly during the COVID-19 pandemic. While they offer opportunities for emotional engagement and community resilience, they also act as vectors for health misinformation, contributing to the global infodemic. Despite growing interest in their communicative power, the role of memes in shaping public perception and misinformation diffusion remains underexplored in infodemiology.

Objective: This integrative review aims to analyze how memes influence emotional, behavioral, and ideological responses to health crises, and to examine their dual role as both contributors to and potential mitigators of infodemics. The paper also explores strategies for integrating memes into public health campaigns and infodemic management.

Methods: A comprehensive literature search was conducted across 3 major databases (MEDLINE, Scopus, and Web of Science), identifying a total of 386 records. Following duplicate removal and eligibility screening, 14 peer-reviewed studies published between 2020 and 2025 were included. An integrative narrative approach was used to synthesize evidence on social media behavior, misinformation dynamics, and digital health campaigns. The analysis was grounded in infodemiological and infoveillance frameworks as established by Eysenbach, incorporating insights from psychology, media studies, and public health.

Results: Memes function as emotionally salient and visually potent carriers of health-related narratives. While they can simplify complex messages and foster adaptive humor during crises, they are also susceptible to distortion, particularly in echo chambers and conspiracy communities. Findings reveal that misinformation-laden memes often leverage humor and disgust to bypass critical thinking, and their viral potential is linked to emotional intensity. However, memes have also been successfully integrated into prebunking strategies, increasing engagement and reducing susceptibility to false claims when culturally tailored. The review identifies key mechanisms that enhance or hinder the infodemiological value of memes, including political orientation, digital literacy, and narrative framing.

Conclusions: Memes are a double-edged sword in the context of infodemics. Their integration into infodemic surveillance and digital health campaigns requires a nuanced understanding of their emotional, cultural, and epistemic effects. Public health institutions should incorporate meme analysis into real-time infoveillance systems, apply evidence-based meme formats in prebunking efforts, and foster digital literacy that enables critical meme consumption. Future infodemiology research should further explore the long-term behavioral impacts of memetic misinformation and the scalability of meme-based interventions.

Introduction

Background

The term "meme" was first conceptualized by Dawkins in 1976 [1] in *The Selfish Gene* as a unit of cultural transmission analogous to genes in biological evolution. Memes, in this sense, are replicable units of information that spread through imitation, adapting and evolving as they traverse social networks.

The integration of digital media into public health discourse has reshaped the way scientific information is communicated to the public. During the COVID-19 pandemic, for example, memes played a dual role: amplifying preventive messages in some cases, while spreading pseudoscientific claims and distrust in others. As noted by the World Health Organization, the COVID-19 crisis has been accompanied by an "infodemic"—an overabundance of information, including deliberate attempts to disseminate misinformation and disinformation, which poses a serious threat to public health communication efforts [2]. Through this period, public health influencers (PHIs) emerged as pivotal figures in bridging the gap between formal medical expertise and public engagement. MacDonald and Wiens [3] argue that these PHIs leveraged memetic bricolage techniques—such as stop motion, collage, infographics, and placarding—to distil complex health information into digestible, shareable content across platforms such as Instagram, TikTok, and Twitter. Their study highlights how this form of science communication not only combated misinformation but also worked toward equitable health advocacy, making public health messaging more accessible to diverse audiences. The role of PHIs in challenging health inequities is particularly notable. Their efforts illustrate that digital advocacy can pressure governmental institutions to enact more transparent, community-driven health policies. By leveraging social media affordances, PHIs were able to redirect the spread of disinformation back toward evidence-based facts, reinforcing the notion that strategic digital engagement is crucial for modern public health interventions [4].

Moreover, MacDonald and Wiens [3] argue that internet memes extend beyond their entertainment value, functioning as strategic communicative tools capable of fostering meaningful engagement with nonexpert audiences on complex topics related to health and science. This perspective is further substantiated by Occa et al [5], who, through a systematic review of online health-related memes, identified these visual-textual artifacts as a promising message strategy for health promotion and education. Their findings indicate that while memes are a promising strategy for health education and awareness, their impact varies significantly based on their content, audience, and context. The review identified that most studies on health memes have focused on the COVID-19 pandemic, with other areas such as mental health, vaccination campaigns, and chronic disease awareness remaining relatively underexplored. Moreover, the review found that only a small fraction of studies has examined the direct impact of memes on behavioral health outcomes, underscoring the need for more experimental and longitudinal studies to assess the efficacy of meme-based interventions. Interestingly, this highlights that memes can serve not only as conduits for health communication but also as mechanisms for reducing stigma associated with certain medical conditions. By integrating humor and relatability, memes may facilitate difficult conversations around health issues, making them particularly useful in areas where traditional communication strategies struggle to engage audiences.

Reynolds and Boyd [6] conducted an exploratory descriptive analysis examining health care workers' perspectives on the use of memes as an implementation strategy in infection prevention. Their findings suggest that memes can serve as effective tools for disseminating evidence-based practices, enhancing knowledge, and improving compliance among health care professionals. This aligns with the concept of memes functioning as "lively data"—dynamic, context-responsive units of digital discourse that adapt to evolving public concerns and sociocultural narratives [6].

The widespread nature of social media ensures that memes reach diverse demographics, but this also raises concerns regarding equity in health communication. In addition, policymakers and public health agencies must consider integrating digital literacy initiatives to equip individuals with the skills needed to critically evaluate meme-based health information before accepting or sharing it [7]. The landscape of health communication has undergone a significant transformation with the advent of digital media. Traditional health campaigns, which historically relied on television, radio, and print materials, are increasingly supplemented or even replaced by digital strategies that leverage the reach and engagement potential of social media platforms. Their effectiveness lies in their ability to engage users emotionally while simplifying complex medical concepts, making them particularly useful in environments where misinformation is prevalent [8].

Virality—the rapid dissemination of content through online social networks—is a key driver of meme efficacy in health communication. According to this, content that is emotionally evocative, novel, and has high informational use is more likely to be shared [9]. In the context of health-related content, positive sentiment and practical use enhance a paper's likelihood of being shared via email or social media, contributing to broader public engagement. This shift has given rise to new modalities of public health messaging, among which memes—highly shareable and culturally relevant digital artifacts—have emerged as a potent tool for engagement, advocacy, and health education. Recent empirical studies highlight the role of memes in mobilizing the medical community for training and advocacy. Wang and colleagues [10] investigated the *GetWaivered* campaign, which used humor-based memes to encourage clinicians to register for opioid treatment training. Their study found that meme-driven content increased web traffic and enrollment in a multidimensional digital awareness campaign to increase Drug Enforcement Administration (DEA)-X waiver training courses, demonstrating the practical application of memes in professional medical education [10].

This duality positions memes at the heart of the current infodemic—a term defined by the World Health Organization as the overabundance of information, both accurate and false, that makes it difficult for individuals to find reliable guidance

XSL•FO
RenderX

during a health crisis. Memes contribute to the dynamics of infodemics by shaping how risk is framed, which sources are trusted, and what behaviors are normalized or rejected [11].

To address these dynamics, this review adopts an infodemiological perspective, as proposed by Eysenbach [12,13], which seeks to understand the distribution, determinants, and impact of health information within digital environments. As a subfield of public health informatics, infodemiology integrates insights from epidemiology, media studies, and behavioral science to analyze how information—accurate or not—spreads through populations and influences health outcomes. Within this framework, memes are conceptualized not only as digital artifacts but also as epidemiological signals that warrant systematic observation.

This review also draws on the concept of infoveillance [14], or information surveillance, to highlight how viral content—particularly memetic formats—can serve as early indicators of emerging health sentiments and misinformation trends. By monitoring these content flows, public health actors may be able to anticipate narrative shifts, identify at-risk populations, and design targeted interventions.

In this context, this paper offers a narrative synthesis of recent empirical studies examining the communicative, cultural, and psychological dimensions of internet memes in health discourse. It aims to map both the risks and opportunities that memes pose in the digital health communication landscape and to offer infodemiologically grounded recommendations for researchers, communicators, and policymakers navigating the intersection of humor, misinformation, and public trust.

Objectives

The primary aim of this narrative review is to critically analyze the impact of internet memes and viral content within the context of health communication, synthesizing recent empirical evidence to elucidate both the opportunities and challenges presented by these digital tools in public health promotion.

Specifically, this review seeks to evaluate (1) the role of memes and viral content in disseminating accurate, evidence-based medical information, including their effects on shaping public perceptions of health topics; (2) the effectiveness of memes in engaging diverse and traditionally hard-to-reach audiences, thereby enhancing participation and interaction in health communication efforts; (3) the potential of meme-based communication to mobilize health care professionals, examining how such digital strategies may influence clinical practices, professional education, and engagement in health advocacy campaigns; and (4) the challenges associated with misinformation propagated through memes and viral content, assessing how these formats may simultaneously contribute to and counteract health misinformation, misconceptions, and conspiracy beliefs.

Methods

Study Design

This narrative review was developed following a structured yet flexible approach, suitable for interpretative and thematic synthesis. While it does not follow the formal protocol of a systematic review, methodological rigor and transparency were prioritized throughout the process. To ensure clarity in the study selection process, a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram was constructed following the updated 2020 guidelines [15].

Search Strategy

A comprehensive search of the literature was conducted in March 2025 across 3 major databases: MEDLINE, Scopus, and Web of Science. The search strategy combined MeSH (Medical Subject Headings) and free-text terms connected by Boolean operators. Terms such as *memes*, *internet meme*, *viral content*, *health communication*, *health promotion*, and *misinformation* were systematically combined to retrieve relevant literature across all 3 platforms. Search equations were adapted to each database's syntax to ensure specificity and completeness.

The search queries were tailored to each database, using combinations of MeSH and relevant keywords, connected by Boolean operators (Table 1).

Table . Search equations of databases.

Database	Search equation
MEDLINE	("Memes"[All Fields] OR "Internet Meme"[All Fields] OR "Social Media"[MeSH Terms]) AND ("Health Communication"[MeSH Terms] OR "Health Promotion"[MeSH Terms] OR "Misinformation"[MeSH Terms])
Scopus	TITLE-ABS-KEY(("memes" OR "internet meme" OR "viral content") AND ("health communication" OR "health promotion" OR "misinformation"))
Web of Science	TS=("memes" OR "internet meme" OR "viral content") AND TS=("health communication" OR "health promotion" OR "misinformation")

Eligibility Criteria

To ensure methodological consistency and the relevance of the included studies, clear eligibility criteria were applied. This review considered for inclusion only peer-reviewed empirical research, encompassing qualitative, quantitative, or mixed-method designs, that explicitly addressed the use of memes or viral content within the scope of health communication. Studies were eligible if they were published between March 2020 and March 2025 and available in either English or Spanish. Priority was given to research that examined the role of these digital formats—such as image macros, short videos, GIFs, and remixable visual content commonly disseminated on platforms such as Instagram, TikTok,

XSL•FO
RenderX

Twitter/X, and Facebook—in disseminating medical information, shaping public perception, mobilizing health professionals, engaging audiences, or addressing health-related misinformation. Studies were excluded if they were not peer-reviewed, lacked original empirical data (such as opinion pieces, editorials, or commentaries), or focused exclusively on general social media usage without specific reference to memes or viral content in health contexts. Publications released prior to 2020 or written in languages other than English or Spanish were also excluded from the review. Moreover, in alignment with the objectives of infoveillance [12], the selection process was informed by the need to monitor and interpret emerging patterns of health communication within digital meme ecosystems, acknowledging their potential as markers of infodemic activity. The detailed selection process is illustrated in the PRISMA 2020 flow diagram in the Results section.

Selection Process

Duplicates were removed prior to screening. The selection process was conducted in 2 phases. In the first phase, titles and abstracts were independently screened by 3 reviewers (ACP, BJ-G, and CS-L) to assess preliminary relevance. In the second phase, full texts of the remaining papers were evaluated in detail, applying the predefined eligibility criteria to determine final inclusion. Discrepancies in paper selection were resolved through discussion and consensus among the 3 reviewers.

Data Extraction and Thematic Organization

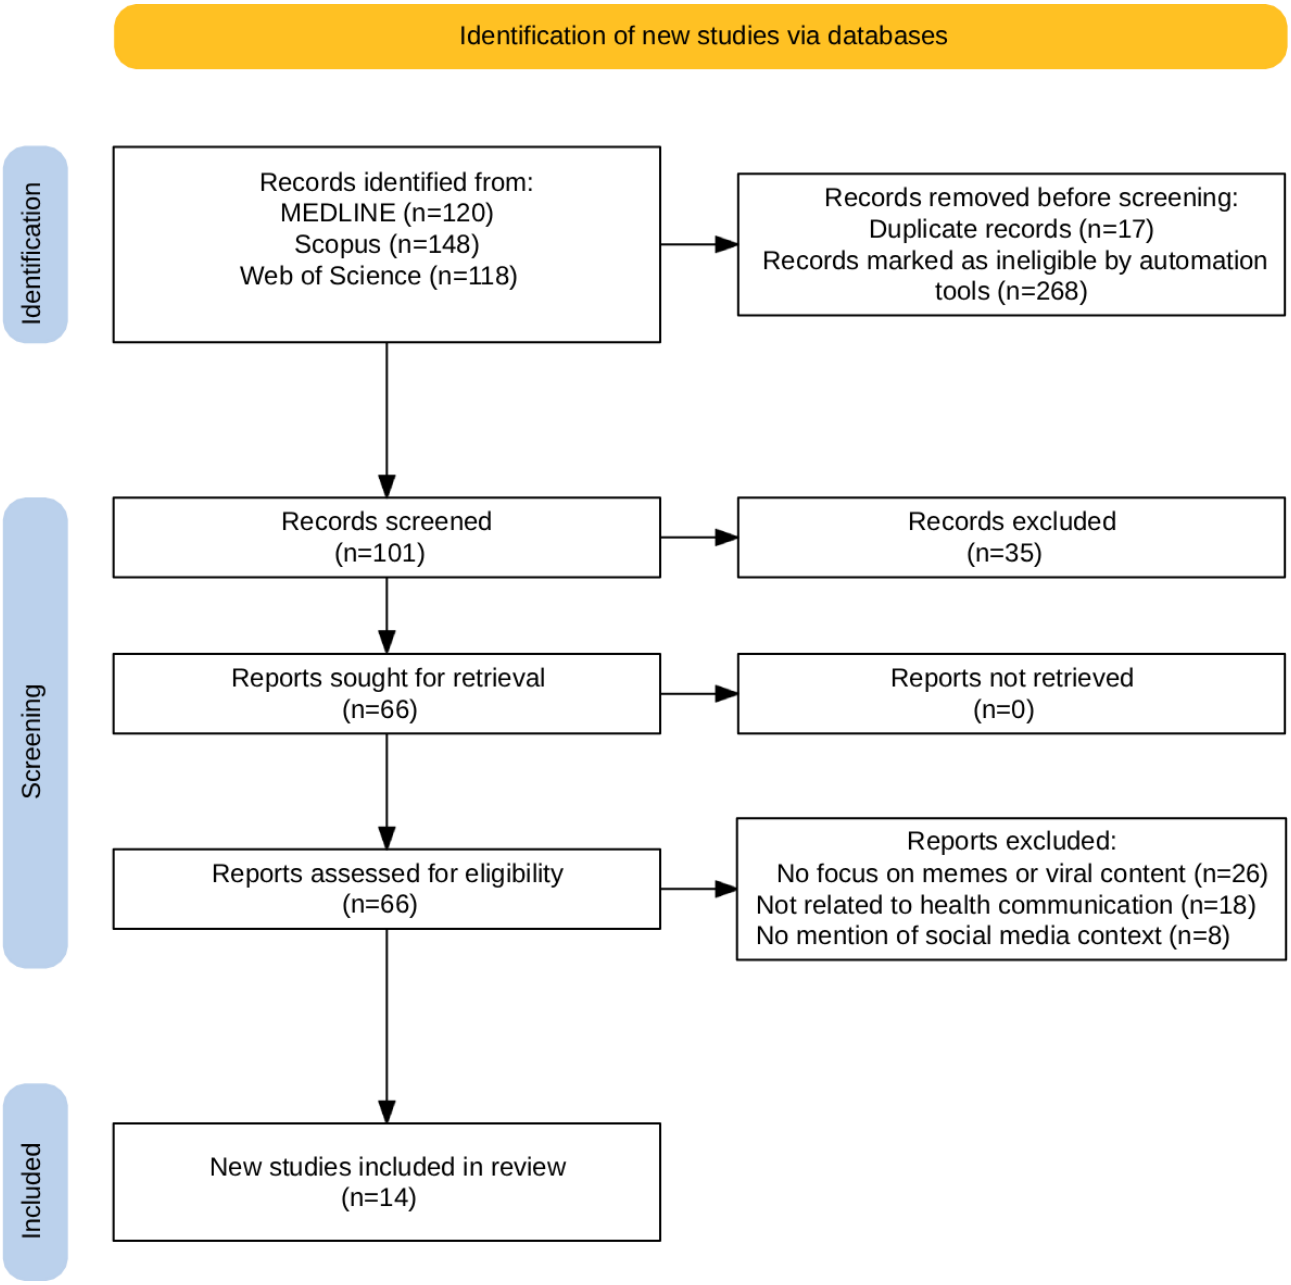
For each included study, relevant information was extracted, including authorship, publication year, study design, objectives, and key findings. The selected papers were then classified according to thematic domains aligned with the review's analytical structure. These domains included the dual impact of social media in health communication, the influence of memes on public perceptions and behaviors, their role in mobilizing community engagement, issues surrounding digital literacy, the interaction between conspiracy theories and public health discourse, the emotional and cognitive mechanisms that underpin humor and misinformation, and finally, evidence-based strategies for combating misinformation, including prebunking, debunking, and combined intervention models.

While the review prioritizes primary empirical studies, relevant secondary literature (eg, systematic reviews and narrative syntheses) was also considered to support theoretical framing in the "Introduction" and "Discussion" sections but not included in the core analysis.

Rigor and Limitations

Although this is a narrative review and not a systematic one, methodological transparency was ensured through clear articulation of the search strategy, criteria for inclusion and exclusion, independent review by 3 researchers, and structured thematic synthesis. Limitations inherent to narrative approaches—such as potential selection bias, the absence of formal quality appraisal, and the interpretative nature of synthesis—are acknowledged and addressed in the "Limitations and Future Research" section.

Results



Search Results

A total of 386 records were identified from 3 electronic databases: MEDLINE (120 records), Scopus (148 records), and Web of Science (118 records). After removing 17 duplicate records (4.4% of total), and excluding 268 records (69.4%) marked as ineligible by automation tools, 101 records remained for title and abstract screening.

During the screening phase, 35 out of 101 records (34.7% of screened) were excluded for not meeting initial inclusion criteria. Of the 66 reports sought for retrieval, all were obtained (0% not retrieved). Upon full-text eligibility assessment, 52 out of 66 reports (78.8% of retrieved) were excluded for the following reasons: 26 out of 52 studies (50%) lacked focus on memes or viral content, 18 out of 52 studies (34.6%) were not related to health communication, and 8 out of 52 studies (15.4%) made no mention of social media context. Ultimately, 14 out of 66 studies (21.2% of assessed full texts) met all eligibility criteria and were included in this integrative review. The study selection process is detailed in the PRISMA flow diagram (Figure 1), illustrating the comprehensive filtering and screening steps undertaken to ensure methodological rigor and relevance.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram for selecting the publications from MEDLINE, Scopus, and Web of Science.

The Impact of Social Media on Health Perception and Misinformation

Social media memes have played a central role in shaping public responses to health crises. Martínez-Cardama and García-López [16] analyzed nearly 1000 Spanish memes shared during the early stages of the COVID-19 pandemic and found that their emotional tone evolved in tandem with societal sentiment—from denial and irony to acceptance and resilience. Far from being trivial, these visual micronarratives served as collective coping mechanisms, capturing the population's shifting mood and transforming complex experiences into emotionally resonant formats that often proved more impactful than traditional public health messaging.

This dual potential of social media is echoed in Jalli's [17] study on TikTok-based activism in Southeast Asia. Youth-led movements strategically used platform-native formats such as duets and stitched memes to mobilize civic action around health and social issues. However, the same affordances that fueled engagement also exposed activists to algorithmic volatility, coordinated harassment, and misinformation campaigns. The study highlights how viral content can simultaneously empower and endanger users, especially in politically unstable contexts.

Isik et al [18] identified a striking gap in how health information is perceived depending on users' professional backgrounds. Their findings show that non–health care participants were more likely to accept health content on social media uncritically, often using it to inform medical decisions without consulting professionals. In contrast, health care professionals exhibited greater skepticism and reluctance to trust digital sources. This divergence underscores the risk of misinformation shaping

XSL•FO
RenderX

public health behaviors, especially among audiences lacking specialized training.

In a broader review of digital misinformation, Altay et al [19] argue against alarmist narratives that exaggerate the reach of false content. They found that misinformation often originates from traditional media and is recycled online, where it competes with satire, critique, and social commentary. Memes, they suggest, are not inherently dangerous but must be understood within their cultural and rhetorical contexts—where humor and ideology often overlap. Their analysis calls for moving beyond simplistic metrics of exposure to embrace more nuanced interpretations of user intent and meaning-making.

Research also reveals that online misinformation affects trust in health care professionals. According to Forgie et al [20], exposure to sensational or misleading health content online may lead patients to question medical advice or turn to unproven alternatives, straining the doctor-patient relationship. Their findings highlight the urgent need for stronger digital literacy frameworks and more robust health communication strategies that anticipate and address the emotional drivers of misinformation.

Mheidly and Fares [21] respond to these challenges with a structured model for infodemic management. Their framework emphasizes timely, transparent, and empathetic communication during health crises, including proactive partnerships between medical institutions and digital platforms. Notably, they advocate for participatory messaging, where audiences are not just recipients but cocreators of health narratives—an approach especially pertinent in the fast-moving, emotionally charged environment of social media [21].

In the context of the Global South, Kubheka et al [22] examined how digital health promotion unfolds in South Africa. While social media platforms offer cost-effective channels for outreach, their potential is unevenly distributed. Structural barriers such as the digital divide, language fragmentation, and limited health literacy reduce impact and risk exacerbating inequalities. The authors call for a more inclusive, equity-oriented strategy—one that integrates cultural sensitivity and community participation into digital health efforts [22].

Finally, Bonnet and Sellers [23] caution that the very characteristics that make memes effective—brevity, humor, and visual impact—also make them potent carriers of misinformation. Their work underscores the need for public health interventions that harness digital virality while maintaining accuracy and promoting critical engagement.

Public perception of health risks is deeply influenced by the type and frequency of media consumed. Li and Zhong [24] found that individuals who rely heavily on digital media are more prone to experiencing heightened anxiety and fear during health crises. This increased emotional reactivity not only shaped behaviors such as mask wearing and social distancing but also led to exaggerated perceptions of threat, including panic buying and avoidance of essential health care.

These dynamics are further explained by media dependency theory, which suggests that during uncertainty, people gravitate toward sources they consider reliable [25]. While traditional media—especially television—had a stabilizing effect on emotions and fostered a sense of control, digital platforms tended to amplify fear and urgency. This aligns with Wakefield et al [26], who previously showed that conventional media remains a cornerstone of authoritative health communication, even in digital-first environments. The challenge for public health communicators is to balance emotional impact with informational accuracy. While fear-based messaging can prompt immediate compliance, it risks eroding trust over time. More effective strategies emphasize self-efficacy, reinforce positive behaviors, and draw on credible, culturally resonant sources.

Memes occupy a unique position in this emotional economy. Basch et al [27] showed that memes promoting health behaviors such as mask wearing gained significant traction during the pandemic. However, many others mocked public health measures or spread conspiracy theories, revealing the double-edged role of humor. A systematic review by Gabarron et al [28] confirmed that memes were frequently used to disseminate false claims about COVID-19 treatments and preventive measures, illustrating how easily engaging formats can obscure misinformation behind jokes or satire.

In contrast to the harmful potential of humor-driven content, Griffith et al [29] explored how memes can also function as tools for resilience and community cohesion during public health crises. Their qualitative study analyzed the role of meme sharing among sexual minority men and nonbinary individuals during the COVID-19 pandemic, revealing how humor served not merely as a distraction but as a form of emotional regulation and collective coping. Memes provided users with a way to process uncertainty, reinforce identity, and maintain social connection under conditions of stress and isolation. This study highlights that meme engagement, particularly when occurring within affirming digital spaces, can offer psychosocial benefits that go beyond entertainment, functioning as informal mechanisms of mental health support. These findings emphasize the duality of meme cultures: while they can amplify misinformation, they also foster resilience and solidarity, particularly among marginalized communities navigating health-related adversity.

Conspiracy Theories and Public Health Memes

Memes have become powerful carriers of conspiracy theories during public health crises, merging visual wit with emotionally provocative messaging. Buts [30] illustrates this with antivaccination memes featuring Mahatma Gandhi and mercury references, which blend historical authority with imagery designed to elicit moral disgust. These memes operate through ambiguity, often subverting their own surface meaning and making it harder to identify and debunk falsehoods. Their rhetorical power lies in leveraging irony and familiarity to bypass rational scrutiny, reinforcing distrust while masking ideology under humor.

Farhart et al [31] deepen this analysis through a large-scale survey, identifying 3 key motivations behind conspiracy meme sharing: genuine belief, alarm signaling to one's in-group, and a disruptive "need for chaos." While belief remains the strongest predictor, the latter motive reflects a broader desire to destabilize rather than persuade. For some users, spreading misinformation

XSL•FO
RenderX

is performative defiance—not misinformation as persuasion but as provocation.

This interplay between identity, emotion, and visual rhetoric intensifies during health emergencies. As van Prooijen and Douglas [32] argue, moments of uncertainty fuel conspiracy beliefs by offering agent-based explanations that feel more intuitive than scientific complexity. This tendency was visible during the COVID-19 pandemic, where narratives about virus origins, treatments, and mandates spread rapidly via memes. Wang et al [33] identified 3 mechanisms behind this dynamic: algorithmic amplification of engaging content, echo chambers that reinforce existing beliefs, and the appeal of cognitive simplicity. These factors not only accelerate misinformation but insulate it from correction.

The role of memes in this environment is particularly insidious because of their emotional stickiness. Panchal and Jack [34], studying forensic patients with a psychiatric disorder, observed how memes fostered an "us versus them" mentality, casting health professionals as oppressive figures rather than trusted advisors. Similarly, Pascual-Ferrá et al [35], analyzing 26,736 Facebook posts during the avian influenza outbreak, found that memes quickly framed public understanding—often mixing scientific facts with ideological tropes such as food regulation skepticism or antigovernment sentiment. Their study underscores the potential of meme monitoring as an early-warning tool for health agencies to detect misinformation trends before they entrench.

The broader problem, as shown in large-scale diffusion studies by Vosoughi et al [36], is that falsehoods—especially emotionally charged ones—spread faster and farther than verified information. Contrary to popular belief, this is not primarily driven by bots but by people. False health claims often provoke stronger emotional reactions, increasing their likelihood of being shared. Memes, by design, condense these claims into viral-ready formats—brief, humorous, and emotionally loaded—making them ideal misinformation vehicles.

Attempts to counteract this trend face significant hurdles. Ecker et al [37] describe the "continued influence effect," in which misinformation persists even after correction. This has shifted the focus toward prebunking—preemptively exposing users to misleading tactics. Studies suggest that prebunking is more effective than reactive fact-checking, particularly when delivered in emotionally engaging, culturally attuned formats.

Humor, Misinformation, and Emotional Engagement

Memes blend humor, visual wit, and ideological commentary, making them powerful tools for emotional engagement in health communication. Their brevity and multimodal nature allow them to not only simplify complex information but also render them susceptible to distortion. Arailopoulos et al [38] highlight how the adaptability of meme formats—image macros, object labels, and screenshots—drives their virality, enabling them to act as cultural signifiers and emotional amplifiers.

Mihăilescu [39] adds that meme creators are often intentional actors and not passive entertainers. They view their work as a means to shape narratives, challenge dominant discourses, and mobilize public sentiment. Their humor is strategic—using irony and parody to spark engagement while maintaining plausible deniability. This blurring between satire and misinformation complicates efforts to hold digital communicators accountable, particularly during health crises.

Anderau and Barbarrusa [40] categorize memes as low-reputation, high-impact communicative tools. They operate through "context collapse," allowing disparate references and emotions to converge in a single visual frame. While this enhances resonance and shareability, it also risks oversimplification and ideological reinforcement. Their taxonomy identifies humor, identity signaling, and emotional valence as core traits in the spread of misinformation.

Importantly, memes are not exclusively harmful. Marx et al [41] show how Brazilian public health agencies used Twitter memes to combat vaccine hesitancy. By incorporating pop culture, local humor, and meme-native framing, these campaigns increased public engagement and countered disinformation narratives. Similarly, Skórka et al [42] found that meme search spikes aligned with COVID-19 mortality peaks, suggesting that people used humor as a coping mechanism. Their sentiment analysis revealed a mix of positive and negative tones—memes simultaneously validated collective fears and diffused them through laughter. Memes can normalize protective behaviors such as mask wearing by framing them as socially shared experiences. However, this potential must be carefully managed. Without grounding in accurate information, humor risks trivializing public health efforts or, worse, endorsing harmful behaviors.

Yet, the emotional power of memes also fuels polarization. Zollo et al [43] demonstrated that conversations around conspiracy content grow increasingly negative over time, a trend that also affects discussions about scientific topics. This escalation intensifies division and reduces receptivity to corrective messages. Farhoudinia et al [44] support this with machine learning models showing that fake news—especially when meme-based—triggers strong emotions such as anger, disgust, and fear. These emotional responses not only increase virality but also reduce critical engagement.

The challenge, then, lies in distinguishing between memes that foster resilience and those that reinforce misinformation. Díaz Ruiz and Nilsson [45] caution that in identity-driven echo chambers, memes are judged less by accuracy than by emotional and ideological fit. Users gravitate toward familiar narratives—even if false—because they offer social cohesion and expressive power. In such environments, truth becomes secondary to affirmation.

Mitigating Health Misinformation

Combating health misinformation requires a proactive and multilayered strategy—one that combines emotional intelligence with structural interventions [46]. Van der Meer and Jin [47] showed that detailed factual corrections are more effective than brief rebuttals, especially when issued by trusted institutional sources. This highlights the need for credible voices and emotionally sensitive framing in health messaging, particularly during crises.

XSL•FO
RenderX

Building on this, Eysenbach [13] proposed a comprehensive infodemic management framework built on 4 pillars: information monitoring, digital literacy, knowledge refinement, and accurate knowledge translation. These pillars underscore that combating misinformation is not just a matter of correcting facts but of building systemic resilience. Misinformation, after all, spreads not only due to cognitive failure but also due to emotional and social dynamics—fear, distrust, and group identity.

A critical distinction in misinformation control is the difference between *prebunking* (inoculation before exposure) and *debunking* (correction after exposure). Roozenbeek and van der Linden [48] demonstrated that prebunking enhances users' ability to recognize and resist misinformation, especially when it is delivered in engaging, gamified formats. Debunking, in contrast, often struggles against the *continued influence effect* [37], where misinformation lingers in memory despite correction.

Recent experimental studies reinforce this view. Barman and Conlan [49] found that prebunking significantly improved participants' accuracy in identifying misinformation, although effectiveness varied across political orientations. Tay et al [50] showed that meme-based prebunking—presenting common misinformation tactics through humor and visual cues—was particularly successful in reducing the spread of implied or emotionally charged falsehoods.

However, misinformation is not easily undone. Ecker et al [37] emphasize that without a clear alternative explanation, corrections often fail. Nyhan and Reifler [51] go further, identifying the *backfire effect*, where factual corrections may reinforce preexisting false beliefs, especially when those beliefs align with political or identity-based convictions. These findings underscore that purely informational strategies are insufficient without emotional and cognitive alignment.

To counteract this, Roozenbeek and van der Linden [52] developed "The Fake News Game," a media literacy intervention rooted in inoculation theory. Participants who engaged in misinformation creation exercises developed greater resistance to false content, suggesting that participatory models are more effective than passive exposure to corrections.

Effectiveness improves further when these strategies are integrated. Bragazzi and Garbarino [53] argue that misinformation persists not because it is persuasive but because it satisfies psychological and social needs—simplifying uncertainty, affirming group identity, and offering emotional closure. Thus, interventions must address both the *content* and the *function* of misinformation.

Silesky et al [54] demonstrated the value of this approach in a study targeting COVID-19 misinformation in Hispanic communities. Their success relied on blending social media monitoring, influencer collaboration, and culturally tailored educational messaging. By acting preemptively and through trusted networks, the campaign improved information retention and reduced susceptibility to misinformation.

Another strategy is source discreditation—undermining the perceived credibility of misinformation sources. Ecker et al [55] found that exposing conflicts of interest or historical falsehoods diminished public trust in misinformation sources, especially when paired with factual corrections. Combining source discreditation with narrative replacement helps audiences both reject falsehoods and adopt accurate alternatives.

Cognitive and behavioral training also enhances misinformation resistance. Ishizumi et al [56] report that interventions focused on critical thinking and peer education build long-term resilience. Empowering individuals to become *correctors* within their communities strengthens their engagement and deepens their understanding, creating social ripple effects.

Discussion

Principal Findings

The findings of this review reveal that internet memes occupy a paradoxical space in health communication: they are simultaneously tools of simplification and distortion. Their visual, humorous, and emotionally resonant nature makes them highly effective for engaging audiences and translating complex medical information into relatable formats. As reported in multiple studies, particularly during the COVID-19 pandemic, memes played a significant role in normalizing preventive behaviors such as vaccination or mask wearing by embedding them in culturally familiar, emotionally appealing content [5,57].

However, these same characteristics make memes vulnerable to misuse. Their brevity and viral design often favor emotional appeal over informational accuracy, leading to oversimplification or misinterpretation. Conspiracy-driven and chaos-driven memes have exploited these dynamics to erode trust in public health institutions, particularly in politicized or polarizing contexts [31,58]. This dual capacity—empowering and destabilizing—positions memes as a double-edged instrument in the digital public health landscape. In addition, to optimize health communication, it is essential to critically evaluate intervention strategies such as prebunking and digital literacy initiatives. Future research should address how these measures can be prioritized, determine which approach may yield the greatest effectiveness, and assess the practical viability of their real-world application. Such an analysis will be pivotal in guiding health institutions toward interventions that both engage audiences and robustly counteract misinformation.

Implications for Public Health Communication

Crucially, the success of health communication via memes depends not only on their esthetic appeal but also on the credibility and authenticity of their sources. Jenkins et al [59] found that users rely on heuristics such as tone, expertise cues, and community endorsement (likes and shares) to judge the reliability of health messages on platforms such as Twitter and Facebook. However, as Helou et al [60] highlight, the frequent lack of conflict-of-interest disclosures among influencers undermines perceived trustworthiness, especially when health content is monetized or promotional in nature.

This affects not only individual perception but also collective behavior. As several reviews indicate, memes can amplify public understanding of health recommendations when integrated into well-designed campaigns [8,61], but they also reinforce misinformation when emotionally charged content spreads

XSL•FO
RenderX

without verification. Farrokhi et al [62] demonstrated that culturally adapted, meme-based messages improved oral health engagement among underserved communities—underscoring their potential when thoughtfully deployed. While humor and memes can enhance engagement and emotional connection with audiences, it is critical to draw ethical boundaries to prevent the trivialization of sensitive health content. To avoid mirroring the same emotional tactics exploited by misinformation, we must strike a careful balance between reach and responsibility—ensuring that clarity, accuracy, and respect for the patient experience remain central to any message we share.

At the community level, memes can function as tools of digital advocacy. When aligned with shared values and experiences, they foster participation, identity, and mobilization—particularly in peer-to-peer spaces where traditional health messaging often fails to penetrate. Yet, their decentralized and remixable nature complicates efforts to ensure message consistency or factual integrity. Brzozowska and Gotlib [63] argue that memes in skin health promotion gained traction precisely because of their emotional relevance and esthetic accessibility—features rarely emphasized in official communications.

In response to the growing threat of memetic misinformation, researchers have explored both prebunking and debunking strategies. Prebunking, grounded in inoculation theory, shows promise in building resistance to falsehoods before exposure—especially when interactive or gamified [58]. Yet, the reactive nature of debunking remains dominant, despite its limited efficacy in meme-based environments. As Henderson and Gow [64] note, the most impactful interventions are those that embed corrective content within culturally and visually familiar formats, rather than relying solely on textual rebuttals.

These findings underscore the urgency of integrating infodemiological frameworks into public health communication. As the memetic dimension of health narratives becomes increasingly relevant, public health actors must develop strategies that anticipate and respond to digital infodemics. Eysenbach's infodemiology model [13] provides a critical lens through which to understand memes not only as cultural artifacts but also as informational agents capable of amplifying or mitigating health risks, lately supported by Schüz and Jones [65]. Recommendations for practitioners include leveraging meme trends for early infoveillance, pretesting memetic content in diverse populations, and designing proactive prebunking campaigns that align with platform-specific engagement patterns. From an infodemiological perspective, the strategic monitoring of viral content—particularly memes—offers valuable opportunities for early detection of misinformation outbreaks. Health institutions should incorporate real-time memetic trend analysis into their infoveillance systems and collaborate with digital content creators to coproduce culturally resonant, scientifically grounded messages. Embedding meme-based strategies within broader infodemic management plans can enhance public trust, reduce information fatigue, and improve the reach and retention of health messages during future crises. Future research should explicitly prioritize these measures, evaluate which interventions are most effective, and examine the practical feasibility of their application in diverse real-world health communication contexts.

Ultimately, navigating the memetic terrain requires more than technical skill or fact-checking infrastructure. It demands a deeper cultural literacy and a willingness to collaborate with digital communities, influencers, and content creators. Memes must not be viewed as marginal or frivolous but as contemporary vehicles of meaning-making—capable of both advancing and undermining public health goals. To engage effectively in this space, public health institutions must evolve, embracing humor without compromising accuracy, leveraging emotion without manipulation, and integrating digital fluency into the core of health communication strategy.

Limitations and Future Research

While this review highlights a growing body of empirical work on the role of memes in health communication, several notable gaps persist in the literature—both in terms of scope and methodological approach. First, a substantial proportion of the existing research remains focused on the COVID-19 pandemic, which, while contextually rich, may limit the generalizability of findings to other public health challenges. Memes related to chronic illness, mental health, reproductive health, environmental health, and health equity remain significantly underexplored, despite the relevance of these topics in online discourse.

Second, most studies identified rely on descriptive or cross-sectional designs, focusing on content analysis or short-term audience reactions. While valuable for mapping trends and themes, these approaches often fall short of capturing the long-term behavioral or attitudinal impacts of health-related memes. There is a pressing need for longitudinal and experimental studies that assess how memes influence decision-making, health behaviors, and trust in public institutions over time.

Moreover, very few studies address the role of meme creators themselves—those individuals or collectives who produce and shape the digital rhetoric circulating in health contexts. Understanding their motivations, creative strategies, and ethical considerations could provide key insights into how public health actors might collaborate with or learn from these informal communicators.

There is also limited exploration of how platform-specific dynamics—such as algorithmic amplification, moderation policies, and visual affordances—influence the spread and reception of health-related memes. These digital ecologies are not neutral backdrops but active agents that shape who sees what, when, and how. As such, future research would benefit from an interdisciplinary approach that integrates public health, media studies, data science, and digital anthropology.

There is a critical need to include diverse cultural and linguistic contexts in the study of health memes. Much of the literature remains Anglocentric, overlooking how meme culture operates across different regions, populations, and health systems. Comparative and multilingual studies could reveal distinct patterns of engagement, resistance, or adaptation that enrich our understanding of memes as global health communication tools. Addressing these gaps will require methodological innovation, interdisciplinary collaboration, and a willingness

to take internet culture seriously—not as a trivial domain but as a dynamic space where health knowledge is negotiated, contested, and reimagined.

Conclusions

This review sheds light on the complex and often contradictory role that internet memes play in health communication. Far from being mere online distractions, memes have become powerful tools for shaping how people engage with and understand health information. Their visual impact, humor, and emotional tone make them especially effective in simplifying complex messages and reaching a wide range of audiences—particularly those who might not respond to traditional forms of public health messaging. Although the current body of evidence highlights the potential of memes as tools for health communication—particularly in fast-paced digital environments—this strategy should be viewed as a promising but still evolving approach. Given the predominance of COVID-19–related studies, the lack of longitudinal data, and a language bias toward English language content, further research is needed to evaluate both the short- and long-term impacts of meme-based messaging across diverse populations and health topics. Memes may offer a valuable addition to public health communication efforts, especially in contexts where engagement and emotional resonance are key, but their use should be guided by ongoing critical evaluation and contextual sensitivity.

Yet, these same qualities can also work against public health goals. The very features that make memes engaging—brevity, irony, and virality—can lead to oversimplification, misinterpretation, or even the spread of misinformation. As the evidence shows, memes can reinforce helpful health behaviors, but they can also amplify doubt, fuel conspiracy theories, or undermine trust in health authorities, depending on how they are framed and who shares them. Moreover, memes have demonstrated potential in enhancing the training and awareness of health care professionals, offering innovative avenues for continuous education and professional mobilization.

These findings suggest that public health professionals and institutions need to move beyond conventional, top-down communication strategies. Instead, they should embrace a more participatory, culturally aware, and digitally savvy approach—one that sees memes not just as potential threats but as opportunities to connect, inform, and empower. This includes working collaboratively with creators and online communities, crafting content that is both engaging and evidence-based, and investing in media literacy to help people navigate the fast-paced, emotionally charged world of digital health content.

In short, memes matter. They are not a passing trend but a central feature of how health narratives are constructed, contested, and circulated online. If used wisely, they can become a powerful ally in promoting accurate information and public trust. But to do so, we must meet audiences where they are—not only with science but also with creativity, empathy, and a deep understanding of the digital cultures they inhabit.

Abstract

Background: Chronic pain, affecting 30.3% of the global population, constitutes a major public health and social challenge. It is associated with disability, emotional distress, and diminished quality of life. Conditions, such as fibromyalgia, headache, paraplegia, neuropathy, and multiple sclerosis are characterized by persistent pain and limited social and medical understanding. This contributes to patient isolation and increases mental health burden. In recent years, social media, particularly X (formerly Twitter), has emerged as a key space for analyzing health-related perceptions and experiences. Its massive use, spontaneity, and broad reach have made these platforms a valuable source for infodemiological research.

Objective: This study aims to analyze posts on X concerning fibromyalgia, headache, paraplegia, neuropathy, and multiple sclerosis, as well as characterize the profile of users involved in these conversations, identify prevalent topics, measure public perception, evaluate treatment efficacy, and detect discussions related to the most frequent nonmedical issues.

Methods: A total of 72,874 tweets in English and Spanish containing the selected keywords were collected between 2018 and 2022. A manual review of 2500 tweets was conducted, and the larger subset was automatically classified using natural language processing methods based on the BERTweet model, previously fine-tuned for content analysis on social media platforms. Subsequently, tweets related to chronic pain conditions were analyzed to examine user types, disease origin, and both medical and nonmedical content.

Results: Of the total tweets collected, 55,451 (76.1%) were classifiable. The most active users were health care professionals and institutions. The primary perceived etiology was pharmacological, and higher treatment efficacy was noted in neuropathy, paraplegia, and multiple sclerosis. Regarding nonmedical content, there were more tweets related to the definition and understanding of the disease.

Conclusions: Social media platforms, such as X, are playing a crucial role in the dissemination of information on chronic pain. Discussions largely focus on the available treatments and the need to enhance public education, using these platforms to correct misconceptions and provide better support to patients.

Introduction

Chronic pain is defined as "an unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage" (International Association for the Study of Pain) [1]. This type of pain is considered chronic when it persists beyond the normal duration of time, typically for more than 6 months [2]. Chronic pain has a global prevalence of 30.3%, representing a significant impact on global health [3], with important implications both on a personal and social level, leading to substantial loss of income, productivity, and quality-adjusted life years worldwide [4]. Moreover, individuals living with chronic pain often report feeling misunderstood by both their social environment and health care professionals [4]. This lack of understanding can exacerbate the emotional impact of pain, leading to feelings of isolation and frustration [5-7]. The absence of an adequate response from health care institutions and professionals may aggravate these feelings, causing patients to feel neglected and hopeless [5-8].

There are several diseases with neurological and musculoskeletal involvement that manifest with chronic pain, such as fibromyalgia, headache, paraplegia, neuropathy, and multiple sclerosis. These pathologies are a leading cause of disability and are associated with high morbidity rates, significantly impacting individuals' quality of life [9]. These pain conditions contribute to mental health issues, such as anxiety and depression, increasing the global disease burden and indirect mortality due to factors such as suicide and accidents resulting from temporary disability [9,10].

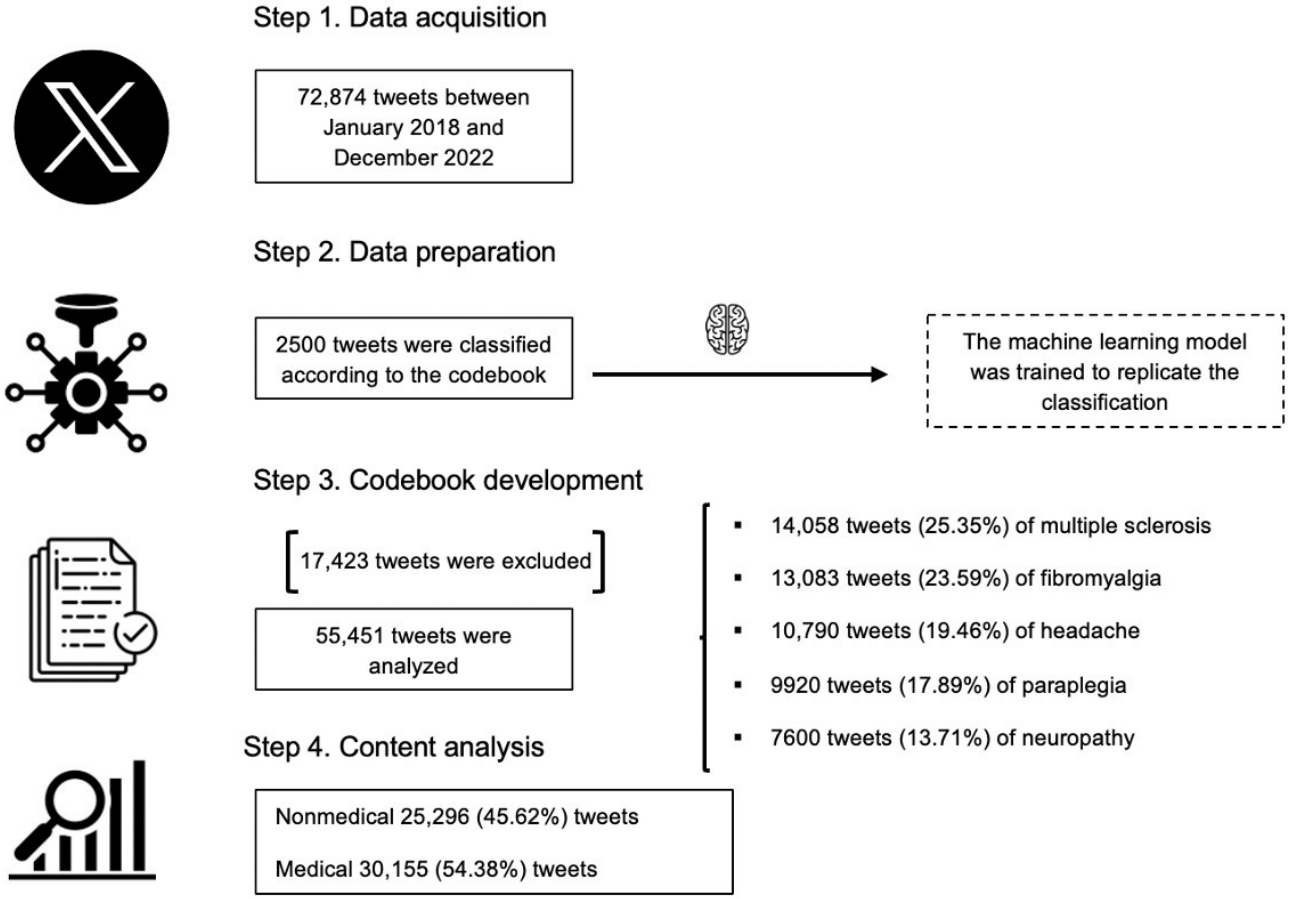
Social media has attracted the attention of millions of users worldwide due to the possibility of rapid communication, access to a vast amount of information, and its wide dissemination [11,12]. According to studies, more than 55% of the global population used social media in 2022 [13]. Therefore, in recent years, medical research has focused on analyzing social media posts to understand diseases and their therapeutic processes better [14]. In addition, social media allows individuals to create and share content in a more informal and spontaneous environment, unlike traditional media, where users are passive consumers [11,15-18]. X (formerly Twitter) is one of the most popular and widely used platforms, considered an effective communication channel [19] and the most used in health research, with content analysis as the main focus [18,20,21]. For example, several studies have demonstrated a correlation between content published on these platforms and real-world clinical events, such as suicide rates [22-24], influenza outbreaks [25], or the misuse of medications and psychoactive substances [26-28].

Only a few studies have used social media to evaluate information related to patients with chronic pain [18,29-36]. In our study, we analyze the natural language used in posts extracted from X regarding 5 chronic pain diseases with the following objectives: (1) conduct a quantitative analysis of posts on X from 2018 to 2022 concerning headache, fibromyalgia, paraplegia, neuropathy, and multiple sclerosis, and determine which disease is most frequently discussed and which generates the greatest interest among users; (2) characterize the user profile that most actively participates in these discussions; (3) identify the etiopathogenesis of these diseases as attributed by X users; (4) analyze public perceptions regarding the treatment of these diseases; and (5) identify the most frequently discussed nonmedical topics.

Methods

Data Collection

This observational study used both quantitative and qualitative approaches and focused on the content of tweets related to a group of chronic pain–associated conditions, as published on the social media platform X. The following conditions were selected: headache, fibromyalgia, paraplegia, neuropathy, and multiple sclerosis, as they are frequent reasons for consultation in chronic pain clinics and are associated with long-term disability and reduced quality of life [37-42]. All tweets referring to these conditions were collected according to the following inclusion criteria: (1) tweets had to be publicly available (ie, from open accounts); (2) they had to include one or more of the following keywords (mentioned in the tweet text): "fibromyalgia," "headache," "migraine," "multiple sclerosis," "polyneuropathy," "neuropathy," "neuralgia," "paraplegia," "tetraplegia," and their Spanish equivalents; (3) they had to be posted between January 2018 and December 2022, a broad time frame that allows for the capture of sustained and meaningful social media discussions on the topic; and (4) Tweets had to be written in English or Spanish, ensuring the representativeness of publications from different regions. Additional metadata were also collected for each tweet, including the number of retweets and likes, as indicators of user engagement and interest in the content [35,43].



Tweet Binder was the tool used to search for and collect the tweets included in this study, which we have used extensively in prior research [35,44,45], and which is capable of accessing 100% of public tweets. Moreover, Tweet Binder does not retrieve tweets from accounts it identifies as potential bots. It applies a hybrid approach that combines Botometer and graph-based bot detection to achieve this. Combining these methods enables more accurate detection. Botometer identifies anomalies at the individual account level while graph-based bot detection analyzes coordinated content propagation at the network level. To filter tweets by language during the search, we used the lang operator provided by the Twitter API v2. For example, lang:en was used to select tweets written in English and lang:es for those in Spanish.

Content Analysis Process

Content analysis was conducted using a deductive approach, grounded in a solid theoretical framework derived from a prior review of the scientific literature. A total of 72,874 tweets were collected (Figure 1). A codebook (Multimedia Appendix 1) was developed to guide the analysis, and a subset of 2500 tweets was manually classified. Although the thematic categories were initially defined in the codebook, some flexibility was allowed during the analysis to refine the classification scheme.

XSL•FO
RenderX

Figure 1. Flowchart of the study design.

Tweets were deemed nonclassifiable if their content was unrelated to the study objectives or if it lacked sufficient information to yield relevant insights. First, we analyzed the type of user. Users were categorized as patients, acquaintances of patients, health care professionals, or health care institutions. This categorization was based on the use of personal pronouns (useful for distinguishing patients from acquaintances), information available in the user's Twitter profile (to identify professionals and institutions), or the tweet content itself (eg, the author self-identifying as a patient, relative, or professional). Next, we distinguished between medical and nonmedical content. Tweets were classified as "medical" when they referred to the origin or cause of the disease or its treatment. Regarding disease origin or cause, we further classified the tweets based on whether they mentioned a previous infection, vaccination, stress, or drug administration. For medical content, we also assessed whether the treatment described was perceived as effective or ineffective in managing chronic pain. Nonmedical content was categorized into three main themes: (1) knowledge or understanding of the disease, (2) commercial or advertising-related issues, and (3) legal concerns. Classification criteria and tweet examples are provided in Table 1.

XSL•FO
RenderX

Table . Category, definitions, and classification examples.

Category	Definition	Example
User type (refers to the individual or organization that posts or shares the tweet).		
Patients	Personal experience with the disease	"Today I'm feeling a bit down. I've been struggling with a migraine since yesterday and ran out of medication."
Patients' acquaintances	Experience of a relative or friend with the disease.	"We're raising money for my dear cousin who has a very aggressive and progressive form of multiple sclerosis."
Health care professionals and institutions	Health care professional or institutional account.	"A 5% lidocaine patch is recommended for the relief of pain associated with neuropathy."
Cause (probable etiology of the disease).		
Vaccine or previous infection	Previous infections or postvaccination processes.	"A moderate correlation has been demonstrated between HHV-6 infection and nerve fiber damage in chronic fibromyalgia."
Stress	Physical or emotional.	"Chronic stress appears to be affecting many individuals suffering from migraines."
Medications	As a trigger for the disease.	"Systematic review of cases: Linezolid-associated neuropathy."
Treatment Efficacy (whether the treatment is perceived as effective or not for chronic pain).		
Effective for chronic pain		"Spinal cord stimulation helps men with paraplegia walk again: Medical News Today."
Not effective for chronic pain		"Focusing fibromyalgia treatment solely on inflammation is unlikely to result in optimal improvements in quality of life."
Nonmedical content		
Knowledge	Refers to general information about the diseases: definitions/theories/ diagnostic criteria/classification, etc	"Fibromyalgia causes widespread body pain, extreme fatigue, and cognitive dysfunction. Symptoms may lead to other complications such as depression and anxiety and can have a significant impact on daily life."
Commercial or advertising	Refers to promotion of the disease or related topics.	"Donations greatly support multiple sclerosis research. Follow the benefit here. Donate to the cause and win prizes."
Legal or judicial	Refers to legal, political, social, or police complaints or claims	"Cannabis regulation is a powerful therapeutic weapon against multiple sclerosis worth advocating for."
Usernames and personal names were removed.		

Machine Learning Classification

Manually analyzing large datasets composed of thousands of tweets is often impractical; therefore, machine learning appears as a crucial tool in data analysis, encompassing 3 primary methodologies, such as supervised, unsupervised, and semisupervised learning [46]. This study focuses on semisupervised learning, which integrates elements from both supervised and unsupervised techniques by using a combination of labeled and unlabeled data to develop a machine learning model that replicates expert evaluations for the classification of millions of tweets. After preprocessing—which included tweet normalization, expansion of negative contractions, removal of special characters and repeated text, and conversion of emojis to their textual equivalents—the tweets were translated into English to improve performance in certain machine learning applications [47]. The dataset, composed of 2500 manually labeled tweets, is then randomly divided into 2 subsets: 75% (1875 tweets) for training and 25% (625 tweets) for testing. The decision to label 2500 tweets was based on a review of similar approaches previously described in the scientific literature [48,49], aiming to ensure consistency with established methodologies. The BERTweet model was selected due to its extensive application in the literature [50,51] and its training specifically on English tweets similar to those we are evaluating. To ensure that these models accurately replicate expert analyses, fine-tuning was conducted with the support of techniques, such as easy data augmentation [52] to balance categories. The models were evaluated on the test set by comparing artificial intelligence–generated predictions with manually annotated labels. To ensure robust evaluation, the F_1-score metric was used, yielding the following results: 0.76 for user type, 0.77 for cause, 0.87 for treatment efficacy, and 0.67 for nonmedical content. These results indicate that the model demonstrates

XSL•FO
RenderX

strong and consistent performance, aligned with similar methodologies reported in the literature [53,54].

Statistical Analysis

The analyses in this study were descriptive, as no formal hypotheses were defined. The primary outcome of the study was the number of tweets containing the study keywords during the study period. Secondary outcomes included the number of likes and retweets of the corresponding tweets, as well as the like-to-tweet ratio and retweet-to-tweet ratio. Subgroup analyses included disease type, user type, disease etiology, medical content (efficacy), and nonmedical content (knowledge, advertising, and legal content). Descriptive statistics, including frequencies, proportions, and ratios, were used to summarize the number of tweets, likes, and retweets. The like-to-tweet ratio was calculated by dividing the number of likes by the number of tweets while the retweet-to-tweet ratio was determined by dividing the number of retweets by the number of tweets. All statistical analyses were conducted using STATA (version 16; StataCorp LP).

Ethical Considerations

This study received approval from the Research Ethics Committee of the University of Alcalá (Code CEI: CEID/2024/1/005) and adheres to the ethical research principles established in the Declaration of Helsinki. This research did not involve human participants directly nor include any human intervention, as it used publicly available tweets. However, special care has been taken not to disclose users' names or any information that could reveal users' identities in this report.

Results

Total Tweet Count

A total of 72,874 tweets were obtained. According to the codebook, 55,451 (76.1%) were classifiable while 17,423 (23.9%) tweets were excluded. The classifiable tweets represented the diseases in the following order: multiple sclerosis with 14,058 (25.35%) tweets, fibromyalgia with 13,083 (23.59%) tweets, headache with 10,790 (19.46%) tweets, paraplegia with 9920 (17.89%) tweets, and finally, neuropathy with 7600 (13.71%) tweets. Based on their content, of the 55,451 tweets, 30,155 (54.38%) were classified as "medical" and 25,296 (45.62%) as "non-medical" (Figure 1). Regarding user engagement with the content, headache stood out with a like-to-tweet ratio of mean 468.80 (SD 33147.94) and a retweet-to-tweet ratio of mean 76.76 (SD 523.88), followed by multiple sclerosis with a like-to-tweet ratio of mean 163.12 (SD 1912.52) and a retweet-to-tweet ratio of mean 47.97 (SD 486.72; Table 2).

Table . Number of tweets published and impact ratios by disease.

Category	Original tweets, n (%)	Ratio like-tweet, mean (SD)	Ratio retweet-tweet, mean (SD)
Multiple sclerosis	14,058 (25.35)	163.12 (1912.52)	47.97 (486.72)
Fibromyalgia	13,083 (23.59)	70.28 (409.09)	27.68 (96.94)
Headache	10,790 (19.46)	468.80 (33147.94)	76.76 (523.88)
Paraplegia	9920 (17.89)	10.37 (137.56)	4.65 (74.49)
Neuropathy	7600 (13.71)	13.03 (125.69)	4.19 (47.92)

Most Active Specific User Group: Health Care Professionals and Institutions

The users who published the most tweets related to chronic pain–related diseases were "health care professionals and institutions" with 24,080 (43.43%) tweets, followed by "patients" with 15,085 (27.2%) tweets and "patient acquaintances" with 4900 (8.84%) tweets. When comparing by disease (Figure 2), "patients" were the most active specific user group in tweets related to headache, with 4865/10,790 (45.09%) tweets and fibromyalgia, with 4815/13,083 (36.8%) tweets. In contrast, for paraplegia, neuropathy, and multiple sclerosis, the users who posted the most tweets were "health care professionals and institutions," with percentages of 43.4% (4305/9920), 67.51% (5131/7600), and 50.54% (7105/14,058), respectively.

However, although "health care professionals and institutions" were the most active users posting about these diseases, public engagement metrics were higher, in terms of likes, for "patients" and, in terms of retweets, for "patient's acquaintances" (Table 3).

XSL•FO
RenderX

Figure 2. Percentage of tweets published for each disease by user type.

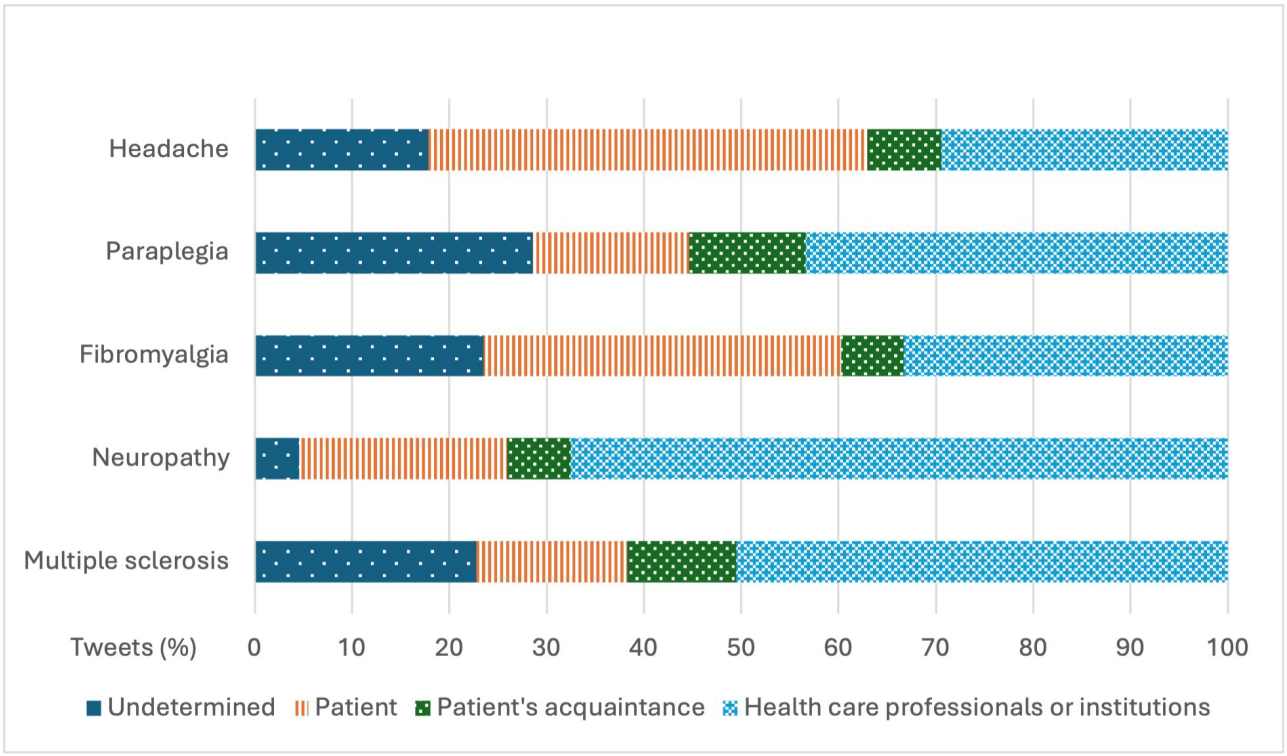


Table . Count of likes and retweets per tweet classified by different categories: user types, cause, medical tweets, and nonmedical tweets.

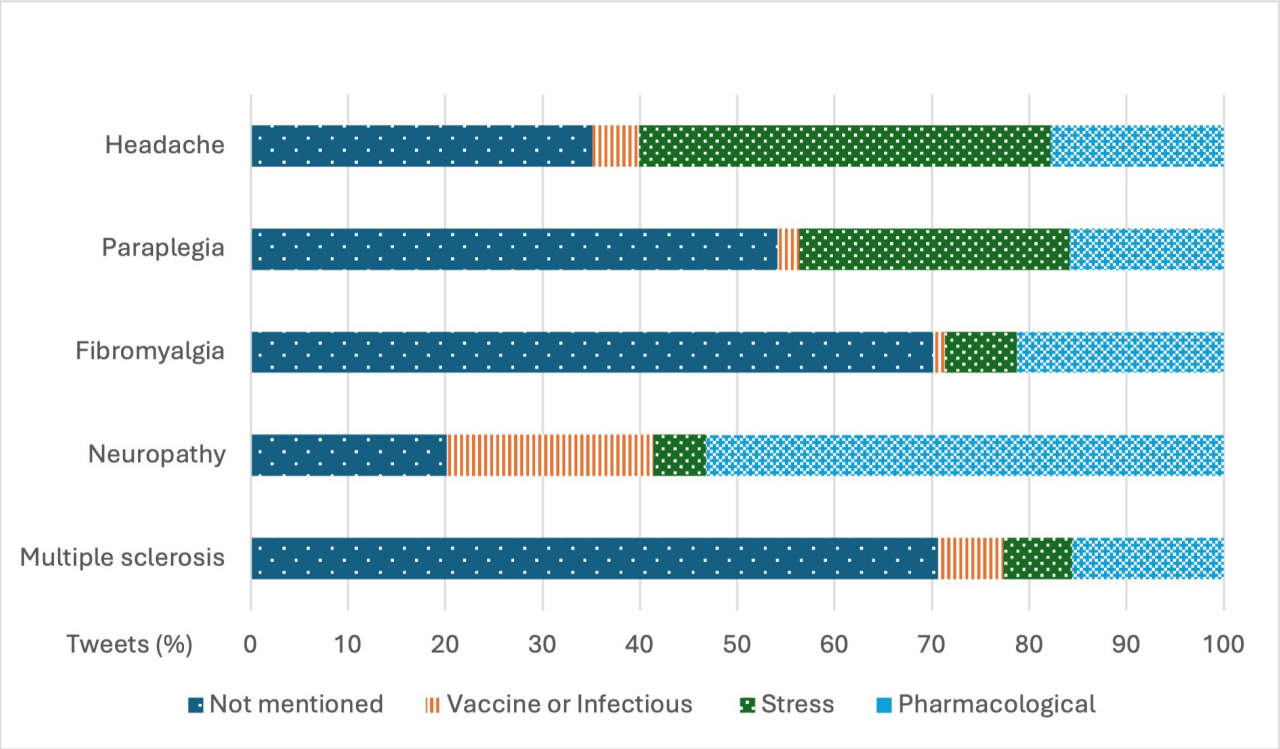
Category	Tweets, n (%)	Ratio Likes–tweet, mean (SD)	Ratio retweet-tweet, mean (SD)
Type of user			
Undetermined	11386 (20.53)	128.30 (1868.42)	38.50 (475.56)
Patient	15085 (27.2)	299.97 (2356.87)	44.24 (231.26)
Patient's acquaintance	4900 (8.84)	258.23 (2616.14)	71.75 (731.90)
Health care professionals or institutions	24080 (43.43)	50.72 (439.10)	20.15 (144.91)
Cause			
Not mentioned	29793 (53.73)	95.91 (1059.18)	28.92 (200.16)
Vaccine or Infectious	3453 (6.23)	191.20 (1512.16)	48.75 (368.00)
Stress	9690 (17.47)	405.75 (3414.54)	64.41 (681.08)
Pharmacological	12515 (22.57)	81.78 (762.54)	23.04 (168.98)
Medical tweets			
Efficacy	20365 (36.73)	98.65 (1209.67)	29.16 (311.48)
Nonefficacy	35086 (63.27)	184.22 (1942.98)	38.46 (360.04)
Nonmedical tweets			
Nonclassifiable/trivialization	8328 (15.02)	431.06 (3301.47)	62.78 (567.84)
Knowledge	23661 (42.67)	59.87 (485.19)	21.53 (146.76)
Commercial	16034 (28.92)	140.20 (1799.59)	37.43 (390.57)
Legal or judicial	7428 (13.4)	164.00 (1335.05)	41.74 (342.92)



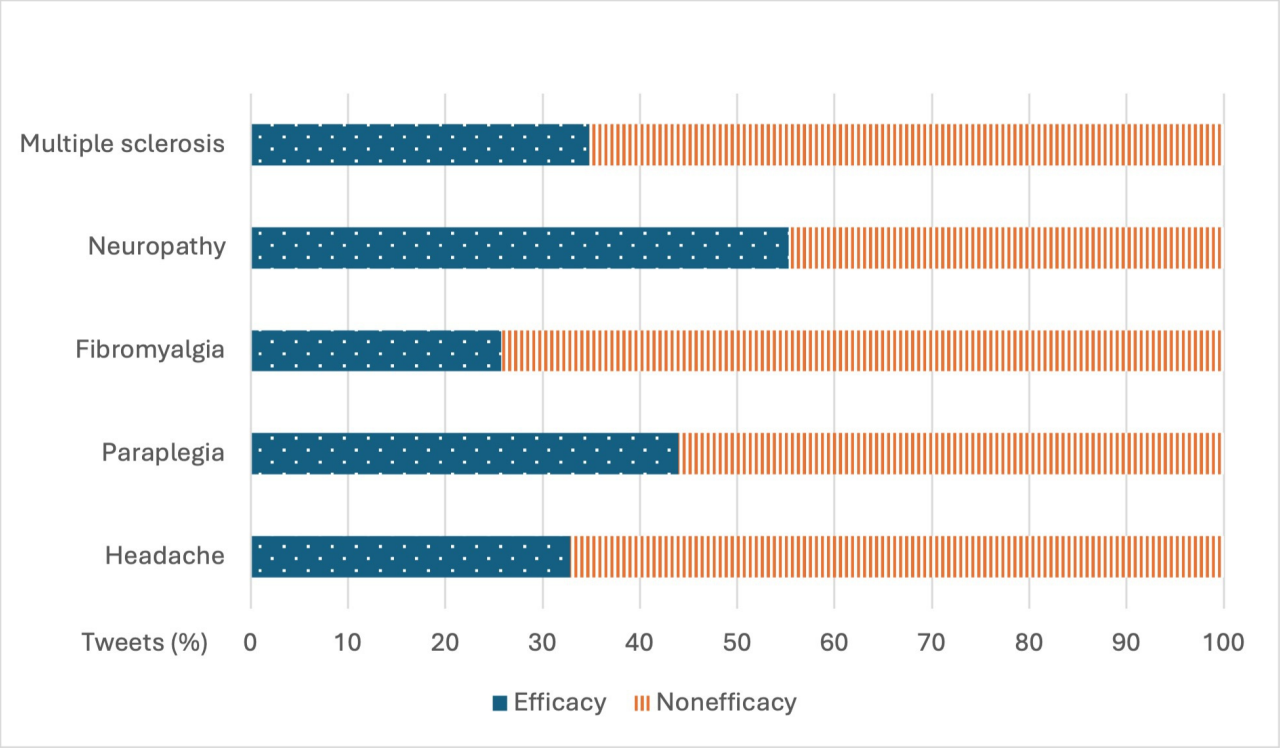
Pharmacological Etiology as the Primary Cause

Out of the 55,451 tweets analyzed, the etiology of the disease was mentioned in almost half of them, with 25,658 (46.27%) tweets. Regarding etiological subcategories, the majority of users identified pharmacological causes as the primary reason for the disease (12,515, 22.57% tweets). Figure 3 shows the distribution of different causes according to the disease. Tweets

XSL•FO
RenderX

related to headache and paraplegia more frequently discussed stress-related causes, whereas those related to fibromyalgia, neuropathy, and multiple sclerosis focused more on pharmacological causes.

Figure 3. Percentage of tweets related to each etiology by disease.



Greater Efficacy of Treatments Used for Neuropathy, Paraplegia, and Multiple Sclerosis

The analyzed tweets were classified according to their medical and nonmedical content, with "medical" tweets (30,155/55,451, 54.38%) being more prevalent than "non-medical" tweets (25,296/55,451, 45.62%). Within the first group, X users discussed topics, such as the efficacy of treatments used for different diseases. We found differences in users' perceptions regarding the efficacy of these treatments (Figure 4). On one hand, diseases associated with chronic pain, such as neuropathy, paraplegia, and multiple sclerosis, had a higher percentage of tweets expressing favorable opinions on the efficacy of their treatments, with 55.26% (4200/7600) tweets, 43.96% (4361/9920) tweets, and 34.8% (4892/14,058) tweets, respectively. On the other hand, X users perceived lower efficacy, or did not mention it in the tweet, regarding treatments used for headaches and fibromyalgia, with only 32.81% (3540/10,790) of tweets and 25.77% (3372/13,083) of tweets reporting good efficacy, respectively.

XSL•FO
RenderX

Figure 4. Percentage of tweets related to treatment efficacy by disease.

Tweets Related to Disease Definition and Knowledge Predominated

Regarding content, Table 4 shows the distribution of tweets among the "non-medical" subcategories. The category with the highest proportion of tweets included references to issues related to disease knowledge, totaling 23,661 tweets, which is 42.67% of the analyzed tweets. This was the main area of interest across all the chronic pain–related diseases studied. References to commercial or advertising topics (16,034, 28.92% tweets) and legal issues (7428, 13.39% tweets) were also detected.

Table . Classification of tweets based on nonmedical content (and their distribution across different subcategories) total and by disease.

Category, n (%)	Total tweets (N)	Headache	Paraplegia	Fibromyalgia	Neuropathy	Multiple sclerosis
Nonclassifiable	8328 (15.02)	3554 (32.94)	1124 (11.33)	1969 (15.05)	791 (10.41)	890 (6.33)
Knowledge	23,661 (42.67)	3164 (29.32)	4596 (46.33)	4701 (35.93)	4541 (59.75)	6659 (47.37)
Commercial	16,034 (28.92)	2764 (25.62)	2727 (27.49)	4140 (31.64)	1296 (17.05)	5107 (36.33)
Legal or Judicial	7428 (13.39)	1308 (12.12)	1473 (14.85)	2273 (17.37)	972 (12.79)	1402 (9.97)

Discussion

Principal Findings

Our main findings indicate that multiple sclerosis and fibromyalgia generated the highest volume of tweets while headache generated the highest level of user engagement. The most active users were health care professionals and institutions; however, the tweets that received the greatest reach originated from patients or patients' acquaintances. Regarding content, the medical perspective predominated, with drug-related etiology being the most frequently mentioned cause by users. A more positive perception of treatment efficacy was observed for multiple sclerosis, neuropathy, and paraplegia, in contrast with a more negative perception in the case of fibromyalgia and headache. Finally, the most frequent nonmedical content was related to general knowledge about the disease.

Our analysis of tweets related to chronic pain conditions, such as headache, paraplegia, fibromyalgia, neuropathy, and multiple sclerosis, follows the model of recent research that uses X to evaluate public interest and communication patterns on health topics [31-36]. The fact that 76.1% of tweets were classifiable suggests that most of the content found was relevant to the study's objectives. Regarding disease distribution, the 2 dominant topics were multiple sclerosis and fibromyalgia, reflecting greater user participation in conversations related to these conditions. On the one hand, multiple sclerosis, being a chronic and disabling disease, may generate more discussion due to its increasing prevalence in recent years [46,47] and its greater demographic diversification, affecting a wider range of racial and ethnic groups [47,50,55]. In addition, new potential risk factors for disease development have been identified [51], as well as disparities in care and health outcomes among patients with multiple sclerosis based on their socioeconomic status. This relationship is significantly influenced by the high cost of

XSL•FO
RenderX

new immunological disease-modifying treatments, which are crucial for managing the disease [52,53]. Therefore, individuals with higher incomes and educational levels tend to experience less disability and less severe symptoms of the disease, even in a context of universal health care access. In contrast, those with lower incomes and educational levels present faster and more severe disease progression [54]. These aspects have contributed to increased public interest and awareness not only among those affected by the disease but also among health care professionals, family members, and researchers.

On the other hand, fibromyalgia also attracts considerable attention due to its controversial nature and diagnostic difficulties, which have led to an increase in public awareness, especially on social media platforms [34]. The like-per-tweet and retweet-per-tweet ratios provide information about the public's interest in these conversations [43]. In this regard, the disease that has generated the most interest is headache. This is due to its high prevalence, being the most common disease among the 5 studied, affecting up to 9.5% of the global population [56,57], leading X users to actively seek support and empathy on social media platforms [58].

Our results also show that individuals with lived experience and their acquaintances appear to be less active in X discussions about chronic pain conditions, while health care professionals and institutions are the most active users, with their content focusing primarily on medical aspects. We expected that individuals with lived experience would be more willing to discuss these diseases, as observed in previous studies [31,32]. The significant presence of health care professionals on X is a positive finding. The use of social media by health care professionals facilitates the dissemination of health-related information and promotes 2-way communication with users [35,36]. However, it is "patients" who speak about their own experiences related to headaches and fibromyalgia. A speculative explanation is that these diseases have a worse social perception compared to other conditions due to the invisibility and subjectivity of their symptoms. The emotional and psychological burden of living with these invisible conditions often leads patients to seek validation and social support. Therefore, these platforms may allow patients to express their frustrations and seek advice from others experiencing similar pain and symptoms [34,59]. These lived experiences could help reduce feelings of invalidation and better tailor therapeutic efforts [60].

Recent research highlights how digital platforms are valuable tools for assessing public perception, understood as the overall perspective expressed by patients, acquaintances, institutions, and other users, regarding the etiology of diseases [61-63]. First, the perception that stress is related to the onset and exacerbation of symptoms in conditions, such as headaches and paraplegia, is supported by the scientific literature. Several studies have found that stress is the main trigger for migraine episodes in a large proportion of patients [63-65], while in the case of paraplegia, although the primary cause is usually physical damage to the spinal cord, stress plays an important role in exacerbating symptoms, such as chronic pain and muscle tension. Studies have shown that individuals with spinal cord injuries may experience increased pain in situations of high stress [66-68].

Second, X users provide insights into how drugs may be implicated in the development or exacerbation of fibromyalgia, neuropathy, and multiple sclerosis. This claim aligns with a review of studies exploring how medications can influence these diseases. For example, in the case of fibromyalgia, the authors discuss how certain medications can cause similar symptoms, as well as induce or exacerbate disease symptoms [69,70]. Several papers also analyze how different drugs can induce neuropathies and review the mechanisms behind nerve damage caused by these medications [71,72]. Finally, a review discusses drug-induced multiple sclerosis-like syndrome and explores the influence of pharmacological treatments on the induction, progression, and severity of the disease [73]. Therefore, all this justifies the increased appearance of these etiological subcategories in user discussions on platforms like X. In addition, we are concerned about how poor treatment adherence for diseases, such as fibromyalgia, neuropathy, and multiple sclerosis, may be influenced by these beliefs about medication and concerns about their long-term adverse effects [74-76].

The analyzed data generally show that "medical" topics were more frequent than "non-medical" ones. Regarding "medical" content, X users discuss the effectiveness of treatments used for the studied diseases to seek support from others going through similar situations and exchange information and experiences about different therapies [77]. In this way, our research improves knowledge about public opinions, for example, on emerging therapies. Notable therapeutic innovations include the use of monoclonal antibodies targeting the calcitonin gene-related peptide, which have shown efficacy in preventing chronic migraines [78]. In patients with spinal cord injuries causing paraplegia, options such as spinal cord stimulation are being explored for pain treatment, with promising approaches enhancing neural plasticity [79-81]. In fibromyalgia, advances in understanding its underlying mechanisms have enabled research into repetitive transcranial magnetic stimulation [79,82] and cannabinoid therapy as potential treatments to relieve pain in these patients [83,84]. Cannabinoids and magnetic stimulation [84], as well as nanomedicine-based therapies [79], are also being explored as future options in neuropathy; the frequent debilitating chronic pain in multiple sclerosis progression has also required the exploration of treatments with cannabinoids [85] and biologic therapies aimed at modulating the immune system and reducing inflammation [86].

Neuropathy and multiple sclerosis, despite being difficult-to-treat conditions, have therapeutic options that are appreciated by patients because they provide significant pain relief and improve quality of life. Advances in treatments for multiple sclerosis and paraplegia have also generated expectations and positive experiences, as reflected on social media [87,88]. Notably, despite the lack of a cure for multiple sclerosis and paraplegia, X users post about the effectiveness of their treatments because they value the improvement in quality of life, personalized therapeutic advancements, and the psychological and social support they receive [81,89-93]. In addition, continuous innovation in research generates hope, reinforcing this positive perception due to the possibility of

XSL•FO
RenderX

maintaining independence and functionality for a longer time [81,87]. However, current treatments for headache and fibromyalgia do not always achieve significant relief, increasing dependence on medications and their side effects [6,94-98]. The limited therapeutic efficacy, the invisibility of symptoms, and the frequent lack of both social and medical understanding generate frustration among patients [26,28,99], which may be reflected in social media data [47], as observed in our study, and helps contextualize differences in treatment perception.

The codebook also revealed a noteworthy theme related to the proportion of information and knowledge about diseases. It has been shown that inadequate knowledge of a specific disease can lead to the stigmatization and discrimination of patients [100]. An example is the historical rejection faced by patients with epilepsy. It was often believed that epilepsy had its origins in malevolent causes or was associated with sin or demonic possession, as well as the theory of epilepsy as contagion and madness [101-105]. These phenomena arise from misunderstandings or insufficient knowledge about why epileptic seizures occur [106]. Similarly, the stigmatization of depression is deeply rooted in the lack of information and understanding about the disease [107,108]. Therefore, chronic pain, which is difficult to quantify and measure, is often minimized or ignored by professionals and society, contributing to a perception of exaggeration or invalidation of the patient's experience. Among the conditions studied, headache and fibromyalgia are the least understood, due to the invisibility of their symptoms, the lack of objective biomarkers, and diagnostic ambiguity [109-111]. Patients often perceive this invalidation from family members, the health care system, and society at large [112,113], which may exacerbate symptoms and negatively impact their emotional well-being [60,113-115].

Studies have demonstrated that when a disease and its treatment options are better understood, patients are more likely to follow medical recommendations and have higher adherence rates [116-119]. However, current treatment options for headache and fibromyalgia exhibit limited efficacy, focusing primarily on symptomatic relief and often being associated with adverse effects [41,42,94-98]. These therapeutic limitations, combined with the multifactorial complexity of these conditions and the perceived lack of validation, contribute to patient frustration [40-42] and diminished trust in the health care system. Such experiences are frequently expressed on social media [34, 41], providing valuable insights into public perceptions of treatment effectiveness. In this context, social media platforms serve a dual role: they facilitate the sharing of emotional and personal experiences and function as channels for health education. The active engagement of health care professionals and institutions on these platforms can help counteract misinformation and provide trustworthy resources, particularly in digital environments where false information spreads rapidly [120,121]. Moreover, these interactions promote more open communication between patients and health care providers, supporting stigma-reduction efforts and enhancing awareness-raising strategies.

Overall, the findings of this study offer practical implications for public health, health communication, and clinical practice. They demonstrate how social media content analysis can complement traditional research, capture real-time social perceptions, and inform more effective education and awareness strategies.

Limitations

When interpreting the findings of this study, several limitations must be considered. Although our search tool accessed 100% of available tweets, some mentions of chronic pain conditions may have been missed due to the use of alternative keywords. The presence of abbreviations, grammatical errors, and colloquial language by users may have hindered the accuracy of data retrieval and analysis. In addition, not all chronic pain conditions were included. The demographic profile of X users, generally younger individuals with specific socioeconomic characteristics, does not reflect the general population, which may limit the generalizability of our findings to broader discussions on chronic pain. As with most qualitative research, the development of the codebook and tweet analysis involves a degree of subjectivity. Although predefined criteria were applied, the analysis was conducted by a single coder, which may have influenced the interpretation of certain messages. Moreover, tweet content may evolve over time, and the inclusion of only English and Spanish tweets could distort the perception of some health-related issues. The potential influence of bots and fake accounts may have affected the data to some extent; however, specific tools were applied to detect or exclude such accounts. Likewise, interactions on X, such as retweets and likes, do not necessarily reflect users' true understanding or perceptions of a topic, but rather the content's popularity or immediate appeal, as well as the influence of accounts with large followings. Finally, our methodological design does not allow for an in-depth exploration of direct relationships between social media use and specific clinical outcomes due to the anonymity of the data obtained.

Nevertheless, this study used a methodology that has been consistently used in previous medical research on X [44-47,50-53], and it offers a valuable approach to exploring the dynamics of social media discourse related to chronic pain conditions.

Conclusions

Our study addresses key aspects related to chronic pain and its implications for public health. It is observed that the main participants in discussions about these conditions are health care professionals and institutions, highlighting an opportunity to improve the dissemination of accurate information and optimize the understanding and treatment of this condition. Social media platforms, such as X, play a crucial role as key resources for discussions about chronic pain among health care professionals and patients. Furthermore, the predominance of discussions focused on treatment reflects the influence of available therapeutic options and their perceived effectiveness. Finally, the study underscores the need to enhance education and public awareness, as a significant portion of the content on social networks centers around the definition and understanding of chronic pain from a nonmedical perspective. This highlights the potential of social media to correct misconceptions and provide better support to patients.

Abstract

Background: Polycystic ovary syndrome (PCOS) is a common endocrinopathy among women that requires self-management to improve mental and physical health outcomes and reduce risk of comorbidity. Digital technology has rapidly emerged as a valuable self-management tool for people with chronic health conditions. However, little is known about the digital technology available for and used by women with PCOS.

Objective: The purpose of this scoping review was to identify what is known about digital technology currently available and used by women with PCOS for PCOS-specific knowledge, self-management, or social support.

Methods: The databases PubMed, Embase, CINAHL, and Compendex were searched using Medical Subject Headings terms for PCOS, digital technology, health knowledge, self-management, and social support. Inclusion criteria were full-text, peer-reviewed publications of primary research from 2010 to 2025 in English about digital technology used for PCOS-specific knowledge, self-management, or social support by women aged 18 years and older with PCOS. Exclusion criteria were articles about pediatric populations and digital technology used for intervention recruitment or by health care providers to diagnose or treat patients.

Results: In total, 34 full-text articles met the inclusion criteria. Given the scope of digital technology, eligible studies were grouped into 7 domains: mobile apps (n=14), internet-based programs (eg, Google; n=6), social media (n=6), SMS text message (n=2), machine learning (n=2), artificial intelligence (eg, ChatGPT [OpenAI]; n=3), and web-based intervention platforms (n=1). Findings highlighted participants' varied perceptions of technology usefulness based on reliability of health care information, application features, accuracy of PCOS or fertility prediction, social group engagement, user-friendly interfaces, cultural sensitivity, and accessibility.

Conclusions: There is potential for digital technology to transform PCOS self-management, but further design and development are needed to optimize the technologies for women with PCOS. Future research should focus on including end users during the design phase of digital technology, refining predictive models, improving app inclusivity, conducting frequent reliability testing, and enhancing user engagement and support via additional features to promote more comprehensive self-management of PCOS.

(JMIR Infodemiology 2025;5:e68469) doi:10.2196/68469

KEYWORDS

polycystic ovary syndrome; digital technology; mobile apps; digital health; self-management; mobile phone

Introduction

Polycystic ovary syndrome (PCOS) is a complex, heterogenous collection of symptoms due to hormonal dysregulation [1], and it is the most common endocrinopathy among women across all races and ethnicities [2]. Characterized by hyperandrogenism, ovulatory dysfunction, or polycystic ovaries, PCOS often manifests with a range of symptoms such as irregular menstrual cycles, hirsutism, and metabolic disturbances [1]. Obesity, insulin resistance, and dyslipidemia are common clinical features in women with PCOS and increase the risk for cardiometabolic diseases and reproductive cancers by ≥50% [3] while negatively impacting women's health-related quality-of-life and psychological morbidity [4]. Treatment guidelines for PCOS are complex and multifaceted, as the Endocrine Society Practice Guidelines recommend medical adherence, cognitive strategies, and lifestyle changes to self-manage day-to-day PCOS symptoms [5] and reduce affected women's risk of comorbid conditions (eg, cardiometabolic) [6]. Thus, there is an urgent need for innovative approaches to help women with PCOS effectively manage their condition.

Digital technology is defined as tools, systems, or devices that can generate, store, or process data, such as smartphone apps, wearable trackers, online platforms, and social media communities [7]. Over the past 3 decades, a range of digital technologies to support health have rapidly developed and realized widespread adoption. Studies have revealed that women

XSL•FO
RenderX

are more frequent users of online health information than men [8]. However, the gendered dimensions of using digital technologies to self-manage chronic health conditions has received little attention. Despite the prevalence of chronic health conditions among women across the lifespan, the little research available is primarily about pregnancy-related conditions or the perinatal period [9,10].

As a chronic condition, PCOS transcends the reproductive years. Study findings indicate that women with PCOS report inadequate information and disconcerting interactions with health care professionals [11,12], such that many women with PCOS pursue health care information and social support via the internet [13,14]. Approximately 98% of women with PCOS searched for PCOS-specific information on Google and 19% joined PCOS support groups or forums found during web-based searches [10]. However, little is known about the breadth of digital technology available for or used by women with PCOS or the features offered to help promote health for women with PCOS. Thus, the purpose of this scoping review was to identify available digital technology used by women with PCOS for PCOS-specific knowledge, self-management, or social support.

Methods

Overview

A scoping review was chosen due to the broad nature of the research question in a relatively new area of interest, that being both digital technology and its purposeful use among women with PCOS. A scoping review is ideal when attempting to categorize the volume, nature, and features of emerging research [15]. This scoping review was conducted using the updated Joanna Briggs Institute (JBI) guidance for scoping reviews [16].

The research question guiding this review was: "What is known about the digital technology currently available and used by women with PCOS for PCOS knowledge, self-management, or social support?" Inclusion criteria were full-length, peer reviewed articles reporting primary research about digital technology used for PCOS-specific knowledge, self-management, or social support by adult (≥18 y) women with PCOS, available in English, and published from the years 2010 to 2025. The year 2010 was chosen to be inclusive of all digital technologies, but with awareness of the rapid nature of technological development in the digital application and website realm [17]. Exclusion criteria were articles that were not primary research (eg, editorials and reviews), research about the pediatric population with PCOS, and studies that used digital technology for intervention recruitment or medical treatment. The pediatric population (≤18 y) was excluded because, although a PCOS diagnosis can be considered in pubescent girls, this age poses diagnostic problems due to characteristics of normal puberty that often overlap with signs and symptoms of PCOS [18]. In addition, the health literacy, design preferences, and access to digital technology of the pediatric population differ from those of adults. We excluded articles about digital technology used for recruitment and by health care providers for diagnosis and medical treatment because we were interested in PCOS-specific digital technology used by women with PCOS for PCOS-specific knowledge, self-management, or social support. Thus, the participants included women aged 18 years and older with PCOS. The concept for this scoping review was available digital technology used by women with PCOS for knowledge, self-management, or social support. The context is open in terms of geographic regions but specific to digital technology used by women with PCOS and not digital technology used for research recruitment nor in health care settings for diagnosis or procedures.

Search Strategy

The search strategy was created using Medical Subject Headings terms for PCOS, digital technology, health knowledge, self-management, and social support. Social support was defined as empathy, encouragement, information, and feedback provided by others with shared experiences [19]. Adapting the strategy based on the database PubMed, the databases Embase, CINAHL, and Compendex were also searched for relevant articles. The search strategies used can be found in Multimedia Appendix 1.

Evidence Screening and Selection Process

The search was completed by 2 reviewers (CB and PJW) using Covidence systematic review software (Veritas Health Innovation). After removing duplicates, the articles were screened by title and abstract. Considering the research question and inclusion and exclusion criteria, copies of the full articles were obtained for studies that appeared relevant. If relevance was unclear from the abstract, the full article was kept for further review. The interrater reliability was strong between the 2 reviewers of the initial screening with a Cohen κ of 0.88. The remaining articles were divided into three-fourth of the research team (CB, PJW, and CH) for individual full-text review. The 3 reviewers collaboratively discussed the inclusion of each article. The selected articles were then read by 2 of the reviewers (PJW and CB) to assign a quality rating. The final selected articles were read again by 3 reviewers (PJW, CB, and CH) to collect data.

Quality and Risk of Bias Assessment

The JBI, an international research organization and global leader in evidence-based health care, was chosen because it offers checklists and rigorous processes for diverse forms of evidence. Using the JBI checklists, 2 reviewers (CB and PJW) critically appraised each article for methodological quality and risk of bias to increase confidence in the findings. The third reviewer (CH) was available to discuss concerns, of which there were none.

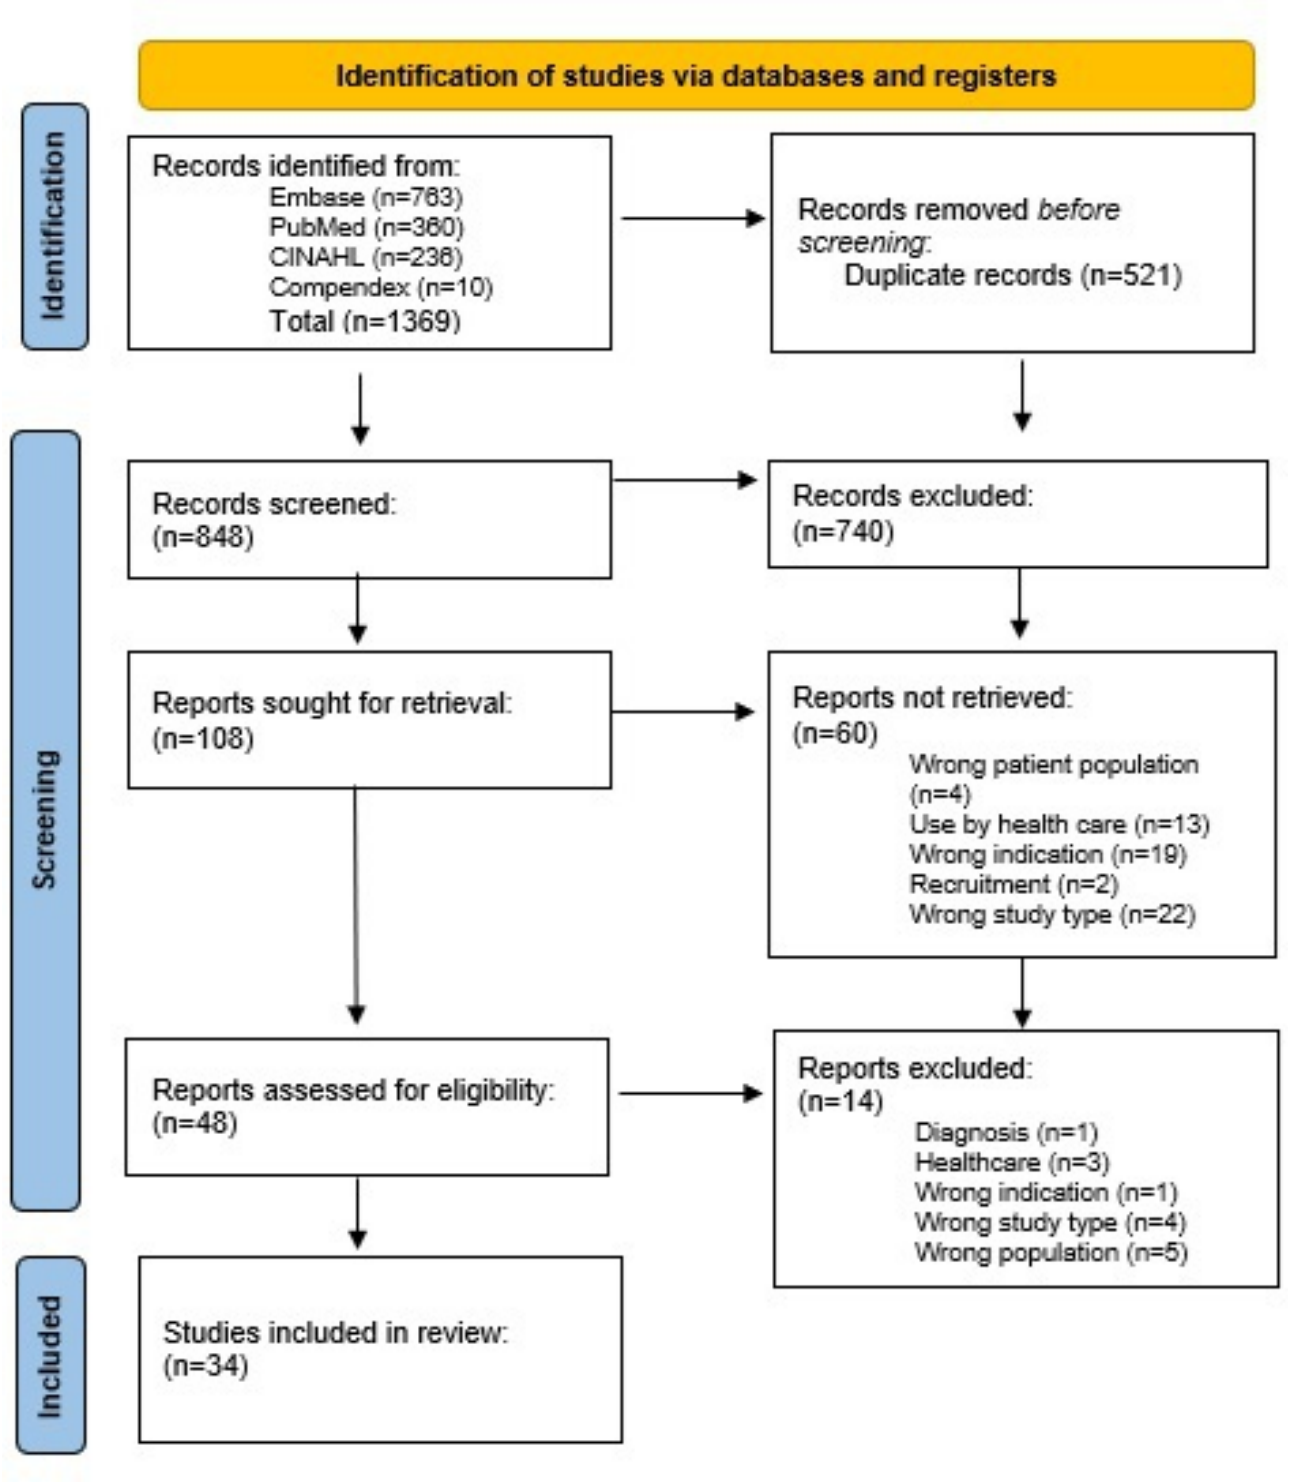
Data Extraction and Analysis

A data chart was created to compile basic study characteristics (eg, authors, publication year, country of origin, and research design), study purpose, the technology used, outcomes, and conclusions. Furthermore, 3 reviewers (CB, PJW, and CH) extracted data and reviewed the data chart to reduce the chance for errors and bias. The research team met several times to code data into categories and summarize the findings. Findings were viewed through the lens of the Unified Theory of Acceptance and Use of Technology (UTAUT). UTAUT was developed by integrating various behavioral theories to help explain the acceptance and use of digital technology. UTAUT emphasizes four key determinants of intention and usage: (1) performance

XSL•FO
RenderX

expectancy (perception that a system helps improve performance or productivity), (2) effort expectancy (perception of ease associated with using the system), (3) social influence (the impact of external social factors such as social norms on use), and (4) facilitating conditions (adequate resources and support to use the system) [20].

Rigor



In addition to iterative review, study rigor was increased by using a scoping review protocol and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR) checklist (Checklist 1).

Results

Overview

A scoping review of the literature revealed 34 full-text articles that met inclusion and exclusion criteria (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) flow chart.

XSL•FO
RenderX

All selected articles met the criteria on the JBI checklists, and were, therefore, included in the review. Data that were systematically extracted and included in the final summary table were author, publication year, research design, study location, sample size, purpose of the technology, and key findings (Table 1). The studies used various research designs, including cross-sectional and randomized controlled trials. Sample sizes varied widely, ranging from 1 [21] to 416,712 [22]. Given the scope of digital technology, eligible studies were grouped into 7 domains: mobile apps (n=14), internet-based programs (eg, Google; n=6), social media (n=6), SMS text message (n=2), machine learning (n=2), artificial intelligence (AI; eg, ChatGPT [OpenAI]; n=3), and web-based intervention platforms (n=1).

Table . Characteristics of included studies (N=34).

Author	Year	Design	Location	Sample size, n	Purpose of technology	Findings
Mobile apps						
Alotaibi and Shaman [23]	2017	RCT[a]	Saudi Arabia	50	To connect women with PCOS[b] with health care providers and help diagnose PCOS	Increased PCOS awareness
Boyle et al [24]	2018	Cross-sectional	Australia	264	To identify pre-existing mobile apps relating to women's health or PCOS that may support self-management	16 apps identified: 8 diet only, 3 fertility or menstruation alone or combined with diet, 5 general information
Rodriguez et al [25]	2020	Multiple methods	United States	9	To assess risk factors and diagnose PCOS based on symptoms	Overall, good estimation of risk, but occasional false positives due to overestimation of certain risk factors
Choi et al [26]	2021	Multiple methods	Korea	30	To promote lifestyle modification and social support for women with PCOS	An integrated app is feasible to develop, but requires further research
Jain et al [22]	2021	Cross-sectional	United States, United Kingdom, India, Philippines, and Australia	416,712	To identify the most prevalent symptoms of PCOS	Common symptoms identified: bloating, high cholesterol, and elevated blood glucose
Sang et al [27]	2022	RCT	China	100	To provide PCOS education, promote lifestyle modification, and provide emotional social support via WeChat (Tencent Holdings Limited)	Statistically greater level of change BMI (87/100, 87.2% lost weight compared with only 68/100, 67.5% in the control) and higher live pregnancy and birth rates
Wang et al [28]	2022	RCT	China	100	To provide theory-based lifestyle modification via an app	Theory-based apps can support weight loss and mental health among women with PCOS
Lee and Lee [29]	2023	RCT	Korea	28	To provide PCOS education and a lifestyle modification program featuring exercise and diet	Apps can support weight loss and reductions in depressive symptoms among overweight women with PCOS
Ou et al [30]	2023	RCT	China	100	To provide health information and patient-provider communication via WeChat and a diet or physical activity tracker via a weight management app	Apps are effective means to provide health information and enable patient-provider communication to help promote health outcomes

XSL•FO
RenderX

Author	Year	Design	Location	Sample size, n	Purpose of technology	Findings
Peven et al [31]	2023	Multiple methods	United Kingdom	24	To track symptoms	88% (21/88) exact match between physician and symptom checker classifications, with 100% sensitivity and 75% specificity. Positive predictive value of 80% and negative predictive value of 100%.
Stujenske et al [32]	2023	Cross-sectional	United States	386	To track menstrual cycles and predict fertility	3 main tracking devices: smartphone apps, temperature tracking, and at-home urine hormone tests. 40% (154/386) used for determining fertility, 27% for tracking symptoms (104/386), and 18% (70/386) for receiving reproductive health education
Trépanier et al [33]	2023	Descriptive	Global	119 apps	To provide menstrual and pain tracking	Free mobile apps with varied approaches; overall, good functionality but poor design and lack of evidence-based approaches to pain
Dilimulati et al [34]	2024	RCT	China	80	To provide videos about healthy lifestyle behaviors	WeChat more engaging and produced more healthy lifestyle changes versus metformin alone; however, metformin significantly lowered HOMA-IR[c]
Hamzehgardeshi et al [35]	2024	RCT	Iran	60	To provide health information and counseling via WhatsApp	WhatsApp (Meta) effective means to deliver intervention that promotes healthy lifestyle behaviors
Internet						
Mallappa Saroja and Hanji Chandrashekar [36]	2010	Qualitative	Global	15	To provide information about PCOS-specific symptom management	Quality of information poor; no website with editorial review
Holbrey and Coulson [37]	2013	Qualitative	United Kingdom	50	To provide social support via online support group discussion forums	Positives: emotional, informational social support; negative: source of worry and anxiety

XSL•FO
RenderX

Author	Year	Design	Location	Sample size, n	Purpose of technology	Findings
Authier et al [38]	2020	Qualitative	France	211	To provide knowledge and social support to infertile women with PCOS	Positive source of experiential sharing; inaccurate and incomplete health information
Hoyos et al [14]	2020	Cross-sectional	United States	759	To find information about PCOS symptoms, support groups, and other PCOS-specific topics via Google	98.2% (745/759) of women used Google to search their symptoms because >50% women were dissatisfied with care; 18.8% (143/759) sought social support.
Malhotra and Kempegowda [39]	2023	Cross-sectional	Global	—[d]	To increase PCOS awareness and provide PCOS-specific information via Google	Global increase of PCOS awareness especially during PCOS Awareness Month, and increased volume of PCOS searches in recent years
Gomula et al [40]	2024	Qualitative	United States and United Kingdom	15	To find health information and social support and compare self to "normal" women via Google	Overwhelming amount of information that lacked reliability and cultural sensitivity and created conflict between phenotypes
Social media						
Gour et al [41]	2021	Quasi-experimental	Turkey	41	To provide PCOS-specific knowledge via video-based, structured, educational module posted on preferred social media site	PCOS-specific knowledge significantly increased among those with at least minimum level of health literacy and familiarity with the Internet
Elhariry et al [42]	2022	Qualitative	Global	8	To understand the impact of PCOS influencers on social media platforms	PCOS influencers report motive as PCOS awareness but all with marketing interest
Clarke et al [43]	2023	Cross-sectional	Jamaica	80 YouTube videos	To provide PCOS content on YouTube	About 30% (24/30) of videos created by physicians. Greater global quality score and video power index among videos posted by health care professionals.
Horvath et al [44]	2024	Qualitative	Global	238 videos	To provide PCOS-specific health information via Tik Tok	TikTok attracts considerable engagement; however, most videos provided low-quality information

XSL•FO
RenderX

Author	Year	Design	Location	Sample size, n	Purpose of technology	Findings
Naroji et al [45]	2024	Cross-sectional	Global	34,308	To provide PCOS-related information across the social media platforms of TikTok, Instagram, and Redditt	About 1.8million views on top PCOS content on TikTok. Weight and diet most common topics. Interactions with medical providers noted in 30% of content. Reddit most engagement under self-management topics.
Afaq et al [46]	2025	Cross-sectional	Global	12,200 posts	To provide PCOS-specific information and social support via X	Higher-quality content with physicians contributing 30% of the discourse; varied engagement
SMS text messaging						
Jiskoot et al [47]	2020	RCT	Netherlands	183	To promote weight loss among women with PCOS and obesity	Group with SMS text message lost more weight than other groups
Dietz de Loos et al [48]	2021	RCT	Netherlands	183	To provide reminders	SMS text message helpful to remind, encourage, and motivate for lifestyle behaviors
Machine learning						
Zigarelli et al [49]	2022	Cross-sectional	India	541	To predict risk factors and diagnosis of PCOS based on health records for patients and providers	Good prediction accuracy: 80% first run and 82.5% second run.
Karia et al [50]	2023	Correlational	India	—	To track complete menstrual health and predict likelihood of PCOS	72.1% - 90.4% accuracy
Artificial intelligence						
Devranoglu et al [51]	2024	Cross-sectional	Turkey	460 queries	To provide answers about PCOS and fertility treatments via ChatGPT	Although fluctuations in performance, accuracy rated high
Shamanna et al [21]	2025	Case study	India	1	To deliver personalized nutrition by predicting postprandial glucose response	Decreased bodyweight, waist circumference, blood pressure, and fasting insulin after 360 days
Ulug et al [52]	2025	Cross-sectional	Turkey	63 questions	To provide answers to PCOS nutrition-related queries via ChatGPT	ChatGPT provides high quality information; readability difficult for average user
Web-based intervention platform						

XSL•FO
RenderX

Author	Year	Design	Location	Sample size, n	Purpose of technology	Findings
Percy et al [53]	2024	Mixed methods	United Kingdom	13 interviews and 58 surveys	To provide theory-based comprehensive PCOS self-management program	Effective for self-management, specifically modest weight loss and reduced depressive symptoms; need for tailoring across lifespan

[a]RCT: randomized controlled trial.

[b]PCOS: polycystic ovary syndrome.

[c]HOMA-IR: Homeostatic Model Assessment of Insulin Resistance.

[d]Not applicable.

Mobile Apps

Mobile apps, software applications designed to run on a small mobile device such as a phone, tablet, or wearable, were the most featured digital technology among the selected articles (14/34; 41%). Mobile apps were used for the following reasons: (1) menstrual tracking to assess for the likelihood of PCOS or predict fertility, (2) symptom tracking to assess for risk factors of PCOS, (3) lifestyle modification, (4) PCOS information, (5) social support, and (6) connection with health care professionals. In one article, the authors identified 16 existing PCOS-specific mobile apps that focused on menstrual tracking, nutrition, or general PCOS education [24], while another article identified 119 free mobile apps for menstrual tracking for women with or without PCOS (eg, Flo [Flo Health, Inc] and Clue [BioWink GmbH]) [32]. Findings by researchers in 2 studies about the use of apps featuring lifestyle modification revealed positive outcomes such as decreased waist circumference [28], modest weight loss, and decreased depressive symptoms [29], and positive chemical and clinical pregnancy rates [26] compared with a standard care control group. Apps can be a feasible means to deliver a PCOS-specific lifestyle intervention [29,30,34,35].

Internet

The category of internet included any type of content electronically transmitted and stored. In 15% of articles (5/34), the researchers studied the Google search browser as used by organizations to promote PCOS awareness [33] and by women with PCOS to search for PCOS health information [30,33,39], nutrition and exercise [14], and social support [14,37,38,40]. In an analytical cross-sectional survey (N=759), researchers reported 98.2% (745/759) of women with PCOS used Google to search their symptoms and 18.8% (143/759) sought support from others who understand PCOS by joining online groups [14]. The Google search engine was reported to be effective at promoting PCOS awareness [39]; however, women with PCOS felt overwhelmed by the amount of information and doubted the information's reliability [38,40].

Social Media

Social media refers to interactive online platforms. Researchers who authored 4 of the articles (12%) included information about online platforms: YouTube (Google) [43] and TikTok (ByteDance), Instagram (Meta), Reddit [45], and X, formerly known as Twitter [42,46]. Authors of the article about YouTube described the analysis of PCOS-specific videos (n=80) posted to YouTube. Of these videos, 37% (30/80) were uploaded by women with PCOS and 29% (23/80) were uploaded by health care professionals. Videos posted by women with PCOS had greater popularity as evidenced by total number of likes; however, they had the lowest quality indicator scores compared with those posted by health care professionals [43]. Contrarily, Twitter or X had higher-quality content with physicians contributing most of the discourse [46]. Engagement was higher on TikTok (approximately 1.8 million viewers) than Instagram and Reddit. The most searched topics on TikTok and Instagram were "weight" and "diet" whereas health information and discussion about health care encounters were the most searched topics on Reddit [45]. A conflict of interest among PCOS-specific content on social media platforms was the presence of promotional advertising: 29% (23/80) of all YouTube videos [42], 45% (23/50) of all Tik Tok videos, and 89% (45/50) of all Instagram posts [45]. As such, social media platforms often involve people, called influencers, who affect the purchasing decisions of others because of their authority, knowledge, or position. Elhariry and colleagues [42] identified the top 100 PCOS influencers and interviewed 8 of them. Influencers self-identified as PCOS advocates and strived to post on multiple media platforms. Connections with marketing companies enabled them to spread their message through brand sponsorships.

SMS Text Messaging

SMS text messaging was featured in 9% of articles (2/34) that reported different analyses from the same study. In the original article, the authors reported the effectiveness of a group-based 3-component lifestyle intervention (nutritional advice, exercise, and cognitive behavioral therapy) to promote weight loss among women with PCOS and obesity. Furthermore, 1 of the 3 study arms received the intervention with an additional 9 months of feedback through SMS text message via their mobile phone [47]. In the second article, they reported on the effectiveness of the intervention on PCOS phenotypical features, such as hyperandrogenism [48]. Overall, the 3-component lifestyle intervention promoted weight loss as compared with the control group, and more so in the group receiving SMS text messages. The authors concluded that SMS text message feedback was useful to remind, encourage, and motivate the women with

XSL•FO
RenderX

PCOS to continue the lifestyle behavior and maintain weight loss.

Machine Learning

In 9% of studies (2/34), apps that included machine learning were developed and tested to track menstrual characteristics [49] and predict the likelihood of a PCOS diagnosis [35]. Machine learning using health care records, patients, and health care providers resulted in 80% - 82.5% accuracy [49], whereas machine learning using various machine learning algorithms ranged from 72.1% to 90.4% [50]. Both study authors noted that currently the accuracy of trackers and PCOS predictors vary widely, especially among free apps, further increasing health disparity in rural areas and among those with lower socioeconomic status.

Artificial Intelligence

AI is technology that enables computers and machines to simulate human intelligence. Thus, AI systems are made to understand and respond to human language, recognize objects, and learn from new information [54]. Furthermore, 6% (2/34) of articles were about the use of ChatGPT to provide PCOS information; 1 about fertility treatments [51] and 1 about nutrition [52]. In both articles, the accuracy of the information was rated high; however, the readability was a challenge for the average user. Shamanna and colleagues [21] completed a case study examining the use of AI to predict postprandial glycemic response to meals and suggesting alternative meal options to avoid glucose spikes. After 360 days of use, the 38-year-old woman with PCOS decreased body weight, waist circumference, blood pressure, and fasting insulin level [21].

Web-Based Intervention Platform

Of the 34 articles, the authors of 1 article (4%) discussed the adaptation of a web-based self-management program based on the identified barriers to self-management and psychological well-being reported from women with PCOS [53]. The existing HOPE program was chosen given its research with multiple other patient groups, such as those with diabetes and cancer, the easier accessibility of web-based intervention platform, and the potential to reach many women with PCOS. Using theory and input from end users, 6 modules were created to include health education, self-care, mindfulness, nutrition, communication skills with health care providers, and goal setting. Now called HOPE PCOS, the program offered features to address multiple components of PCOS self-management and was deemed ready for feasibility testing [53]. However, it was not complete as it omitted physical activity or health-specific needs of older women with PCOS.

Key Findings With a UTAUT Lens

Performance Expectancy

The primary reasons women with PCOS used digital technology was to find health information about PCOS treatment and self-management, track menstrual characteristics to determine fertility, and assess the likelihood of a PCOS diagnosis. As expected, women quickly and conveniently found health information with a Google search, yet they reported the volume of information as overwhelming and the content contradictory [40]. Many of the free apps for menstrual tracking lacked reliability [33,50]. Women with PCOS also expected a confidential, secure platform for social support with others who understand PCOS. Overall, women with PCOS, the end users of PCOS-specific digital technology, expected an interactive, comprehensive, evidence-based, and user-friendly platform that assisted with self-management, health behavior tracking, interaction with health care providers, and social support [14,24,26,33,40,53]. Digital technology incorporating these features was found to help promote weight loss and decrease depressive symptoms [28,29,45] and improve biochemical markers such as hyperandrogenism and ovulatory dysfunction [48].

Effort Expectancy

Women with PCOS report the expectation of an easily accessible and user-friendly platform [23,25,27,28]. Most apps were found to be easily accessible and user-friendly, although engagement was often low, especially in interventions relying on self-motivation [20,33]. However, non–PCOS-specific apps (eg, Flo and Clue) were criticized for insufficient customization, making the information more difficult to use [22,24]. Only one form of digital technology, the website HOPE PCOS, incorporated end user input during the design phase [53].

Social Influence

PCOS awareness was increased through information posted on social media. Some studies noted low involvement in public social support groups [14]. Apps with integrated social functions, such as private networks, demonstrated higher engagement [23,27], especially if the end users shared more in common (eg, life phase) with peers than the illness experience [23,39,40].

Facilitating Conditions

Several facilitating conditions were found to be deficient and negatively affected digital technology use among women with PCOS, including lack of accessibility (eg, cost of Wi-Fi or platform) [33,53], content that required high health literacy [46,51,52], and concerns about the reliability of health information [14,24,40,44]. Women with PCOS indicated that the currently available digital technology is helpful but does not address all their needs [24]. Thus, the lack of a comprehensive set of features deterred regular use of any one type of digital technology [24,47,48].

Discussion

Principal Findings

Of the selected 34 articles for this scoping review, the researchers' main goals across the studies included (1) assessing usability, engagement, and performance of different types of digital technology to meet needs of women with PCOS; (2) enhancing knowledge, symptom tracking, and lifestyle modification via digital technology; and (3) predicting the risk of PCOS through machine learning and symptom-tracking apps. A clear expectation of any digital technology was PCOS education. In a large international cross-sectional study of women with PCOS aged 18 - 45 years (N=1256), approximately

XSL•FO
RenderX

65% (n=816) reported dissatisfaction with information received from health care professionals and the need for self-directed research [55]. Findings from this scoping review indicate concern about the quality and reliability of online health information. Most online information was posted by other women with PCOS based on anecdotal evidence. Higher-quality content was found on Twitter or X and ChatGPT. The primary users of both platforms have college degrees and represent technical sectors, education, research, or business [56,57]. Unfortunately, as information quality increases, readability for the average user decreased.

A significant amount of PCOS content is associated with commercial interests or promoted by influencers with market interest [40,42,58]. The impact of social media influencers on health outcomes is a growing area of research. In a cross-sectional survey of participants, 59% (137/232) stated that they prefer to follow social medial influencers on social media platforms compared with nonsponsored posts [58]. Most research about influencers have focused on their marketing of diets or the impact of their imagery on body image dissatisfaction [59]. While not entirely negative, this type marketing can be misleading and harmful for individuals with vulnerabilities such as body image concerns [60], which are prevalent among women with PCOS [61].

Consistent with previous studies, most women with PCOS preferred apps for PCOS self-management and personal data tracking given their ease of use in terms of time and space [62]. Many apps are currently available for menstrual tracking; however, most are not equipped to interpret irregular cycles [63], a clinical feature of many women with PCOS [1]. Machine learning advances hold potential to improve the accuracy of menstrual trackers and PCOS predictive models [49,50]. Women with PCOS across the lifespan have also expressed need for reliable PCOS-specific apps that offer an evidence-based, comprehensive approach to self-management, are interactive with both others with PCOS and health care providers, and target multiple outcomes [64,65]. In this scoping review, the app AskPCOS (Monash Centre) and the web-based program HOPE PCOS, were the only digitally based platforms to approximate a comprehensive approach [24,53].

Social media platforms were a common source of social support among women with PCOS because of the asynchronous access to a larger group of individuals who share similar life experiences or interests. Similar to findings from a systematic review about social connectedness among individuals with chronic health conditions [66], engagement diminished over time as women with PCOS sought more common ground than the illness experience, such as life stage (eg, student, mother, and retiree) and, therefore, overall health goal (eg, fertility vs risk reduction of comorbidities) [14,23,26,31,40]. Thus, many social media platforms could benefit from tailoring to reach specific subgroups of women with PCOS, including those with different phenotypes and sociodemographic characteristics (ie, race and residential location).

While digital technology confers several benefits, other facilitating conditions, such as accessibility due to cost or geographic location, remain issues among many women with PCOS. These digital determinants of health encompass technological factors that can influence the access and use of information for self-management, which, in some cases, can potentiate existing sociodemographic inequities in health care [67]. Digital health literacy, or the individual's ability to find, understand, appraise, and apply health information from electronic sources [68] is an emerging priority as people regularly interface with digital technology for health information. The design and development teams of digital technologies could benefit from consideration of digital determinants of health at the onset and the inclusion of a diverse sample of end users for input on use, useability, and aesthetics. In addition, the development of a system to regularly evaluate, score, and post the reliability of health care information on digital technology could empower women with PCOS as they choose digital technology to use and apply electronic health care information.

Assessing the findings of the scoping review through the lens of UTAUT helps more clearly identify future directions for digital technology used by women with PCOS. For performance expectancy, women with PCOS prefer an interactive PCOS-specific app with comprehensive features, including health care education (eg, diagnosis and treatment), lifestyle modification (eg, physical activity, nutrition, and stress management), personal data tracking, interaction with health care providers, and peer support. They expect reliable, evidence-based information that involves accurate predictions of diagnosis and fertility, promotes positive health outcomes and is unencumbered by commercial interests. For effort expectancy, women with PCOS want an easily accessible, user-friendly, and pleasing interface. For social influence, women with PCOS readily use more popular modes of digital technology to connect with others with PCOS; however, motivation to maintain usage is low due to exclusion of subgroups of women with PCOS and lack of sociodemographic context sensitivity. For facilitating conditions, digital technology with more features and higher reliability may cost more, presenting an economic barrier for some women with PCOS. While mobile phone use is rapidly increasing, including across low- and middle-income earning countries, Wi-Fi access may be unavailable [69].

Limitations

By using a systematic, comprehensive search strategy, the reach and rigor of the scoping review was increased. However, only records available in English were examined, which may skew the distribution and recognition of studies. The search of only 4 databases was a limitation, as it may have resulted in the omission of relevant literature. However, we included Embase and PubMed, which are considered among the most comprehensive research databases. Digital technology is a rapidly evolving sector, and advancements are made constantly. Additional PCOS digital technologies may have been developed since the time the scoping review was conducted. While wearables, such as fitness trackers, are most likely used by women with PCOS and have potential to aid self-management, no articles were found about wearables specifically for or preferred by women with PCOS.

XSL•FO
RenderX

Conclusion

The findings of this scoping review revealed that digital health technologies, particularly mobile apps, hold promise for supporting women with PCOS. Future research should focus on advancing user-centered design for apps aimed at managing PCOS, with an emphasis on usability and performance expectancy while accounting for sociodemographic differences and disparities. Health care professionals should also be included to corroborate health care information and increase the likelihood of their endorsement to patients with PCOS. There is potential for digital technology to transform PCOS self-management, but further design and development are needed to optimize these technologies for women with PCOS.

Acknowledgments

The authors would like to thank the ACORN Center in the University of South Carolina College of Nursing for its support during this study. The authors appreciate Dr Sara Donevant for her review and support and Amy Edwards for her assistance with the search strategies.

Abstract

Background: Misinformation on social media during natural disasters has become a significant challenge, with the potential to increase public confusion, panic, and distrust. Although individuals rely on social media platforms for timely updates during crises, these platforms also facilitate the rapid spread of unverified and misleading information. Consequently, misinformation can hamper emergency response efforts, misdirect resources, and distort public perception of the disaster's true severity.

Objective: This narrative review aims to (1) critically evaluate the available evidence; (2) unpack the dynamics of misinformation on social media in the context of natural disasters, specifically natural hazards, shedding light on the challenges, implications, and potential solutions; and (3) develop a conceptual model linking misinformation, public impact, and disasters, grounded in sourced evidence.

Methods: The narrative review examines the impact of social media misinformation in the context of natural disasters. The literature search was conducted using the PubMed database and Google Scholar in April 2024. Studies eligible for inclusion were published in English, with no restrictions on publication date, geographic region, or target population. The inclusion criteria focused on the original research that examined social media misinformation related to natural disasters, specifically natural hazards.

Results: From an initial pool of 173 studies, 9 studies met the inclusion criteria for this review. The selected studies revealed consistent patterns in how misinformation spreads during natural disasters, highlighting the role of users, some influencers, and bots in amplified false narratives. The misleading messages disseminated across social media platforms often outpaced official communications, resulting in reduced trust and exacerbating anxiety, stress, and fear among affected populations. This heightened emotional response and erosion of trust in official communications influenced an individual's susceptibility to the misinformation and prompted inappropriate actions. Consequently, such actions led to resource misallocation, overwhelmed emergency services, and diverted attention away from genuine needs. Collectively, these factors negatively impacted public health outcomes and diminished the effectiveness of emergency management efforts, as illustrated in the conceptual model developed to provide a greater understanding of this critical area of study.

Conclusions: This narrative review highlights the significant impact of misinformation in the context of natural disasters, specifically natural hazards. It stresses the urgent need for disaster preparedness and response plans that include targeted interventions such as real-time misinformation detection technologies, public education campaigns focused on digital literacy, and proactive debunking initiatives. Implementing these strategies can help mitigate the harmful effects of misinformation, strengthen public trust in official communications, enhance the effectiveness of disaster response, and improve public health outcomes.

(JMIR Infodemiology 2025;5:e70413) doi:10.2196/70413

KEYWORDS

misinformation; infodemic; social media; natural disaster; preparedness

Introduction

Social media platforms have increasingly become essential tools during natural disasters, enabling real-time communication, rapid information dissemination, and enhanced public awareness and safety [1]. However, these platforms also facilitate the rapid spread of misinformation, significantly complicating disaster management and public health responses [1-3]. The dissemination of misinformation during disasters can lead to

XSL•FO
RenderX

heightened public anxiety, confusion, resource misallocation, reduced effectiveness of emergency responses, and diminished trust in official communications [4-7]. For example, during Hurricane Sandy in 2012, false tweets about the New York Stock Exchange flooding and fabricated images of the storm spread widely, causing public panic and confusion [4]. Similarly, misinformation during Hurricanes Harvey and Irma in 2017 led to widespread fears about mandatory ID checks at shelters, discouraging undocumented immigrants from seeking safety [5]. Furthermore, the spread of misinformation can also delay emergency response efforts, as observed in the 2018 Kerala floods, where misleading social media posts hindered rescue operations [6].

A key challenge in addressing misinformation during natural disasters lies in the timing and immediacy of such events. They often occur with little warning, leaving minimal time for preparation. For example, while a hurricane may be predicted a few days in advance, its impact is typically sudden and severe. This rapid onset and escalation of natural disasters can amplify the spread of misinformation on social media platforms in unique ways. For this reason, examining misinformation specifically within the context of natural disasters offers valuable insights into the role of social media in crisis communication.

Additionally, the sheer volume of misinformation circulating online poses substantial challenges for government agencies, humanitarian organizations, and health systems, entities that are paradoxically central to disaster response. To counter these challenges, coordinated efforts between governments, social media platforms, and the public are essential to ensure the integrity of information during disasters. For example, automated misinformation detection systems implemented by platforms like Twitter (subsequently rebranded X) have been proven beneficial during hurricanes by flagging misleading content related to emergency shelters and procedures [5]. In parallel, public digital literacy initiatives have demonstrated potential in reducing misinformation by the public's ability to critically assess online content [8]. Nevertheless, research suggests that misinformation spreads more rapidly when official communications are unclear or delayed, highlighting the need for timely, transparent, and proactive crisis communication strategies [9].

There are several terms to describe inaccurate information, such as fake news, rumors, propaganda, infodemic, disinformation, and misinformation. This review will focus on misinformation, while adopting a broader lens to also encompass false information intentionally shared (disinformation), as it provides a more holistic account of the impact on public health and disaster response, whether intentional or not.

While numerous accounts document specific incidents of misinformation during events such as hurricanes, floods, and earthquakes [4-6,9], much of the literature focuses on isolated cases. This narrow focus limits our understanding of broader patterns and systematic impacts across different types of disasters and geographic regions. The absence of an integrated synthesis constrains our ability to comprehend how misinformation influences public perceptions, behavioral responses, and the overall effectiveness of emergency response [2,10,11].

Therefore, this narrative review aims to address this gap by synthesizing and consolidating available evidence on misinformation on social media during natural disasters, identifying key patterns, dynamics, and impacts. Additionally, a conceptual model will be developed as part of the review to clarify the relationships between misinformation origins, public impact, and disruptions in emergency responses, informed by sourced evidence [4-6,8,9,12-15]. By synthesizing available research, this review may support policy makers, emergency responders, and public health officials in designing targeted strategies to mitigate the spread of misinformation. Ultimately, strengthening the resilience of disaster response systems and safeguarding public health outcomes.

Methods

Study Design

The methodology for this narrative review is grounded in established principles from relevant literature to guide the review process effectively. These encompass a structured process and have been adapted from the guidelines recommended by the Joanna Briggs Institute [16] as follows.

- The topic and research question were defined, and the criteria that determine whether literature will be included or excluded were created.
- A search strategy was developed and executed, specifying keywords, subject headings, and Boolean operators.
- An initial screening of titles and abstracts from the search results was conducted to assess relevance.
- A detailed full-text review of articles was performed, based on predefined inclusion and exclusion criteria. The screening process results were documented using a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart for transparency.
- Relevant information was extracted from the included studies to support and inform the findings of the review using a standardized data extraction tool.

Also, the Cochrane Handbook for Systematic Reviews of Interventions was used to develop the protocol for this review (PROSPERO [International Prospective Register of Systematic Reviews] CRD42024542111).

The initial search was done by SH. The screening and the full text review were done by SH and EP. Data extraction and synthesis were done by all authors. Any disagreement was solved in consensus meetings, which led to an agreement. The research team consisted of members with different backgrounds relevant to this study.

SH's experience supporting disaster management, digital transformation programs, and national COVID-19 pandemic response initiatives has deeply influenced her approach toward organizational efficiency, resilience, and strategic foresight.

MG, an associate professor of the organization, management, and digital, applies sociotechnical systems thinking to align social and technical dimensions in health care and business,

advancing theory by linking STS principles to digital transformation challenges while also integrating broader cultural, behavioral, and political perspectives on social phenomena.

EP is a public-health specialist and senior lecturer (University of Crete, University of West Attica, and Maastricht University) whose 2-decade career spans R&D (Research and Development), evidence generation and synthesis, HTA, digital health, and artificial intelligence (AI). Since returning to academia, she combines academic research with policymaking and advocacy work, currently serving as president for Global Health and vice president for HTA (Health Technology Assessment) at The European Public Health Association (EUPHA) and chair for RWE & AI at HTAi.

SE, Professor of Public Health Technology Assessment and Scientific Director of the Care and Public Health Research Institute, specializes in health-economic review methods, scoping, narrative, systematic, and meta-analyses and created the widely adopted Consensus Health Economic Criteria list and accompanying guidelines for systematic reviews of economic evaluations.

All research team members are aware that experiences derived from their different roles and positions have shaped their own perspectives. However, the diversity in backgrounds helped to broadly reflect on the findings of this study.

Search Strategy

The search was conducted in April 2024. The primary source to retrieve information was the PubMed database, because of its primacy as a reputable source of public health research. The paucity of results from that source led to expanding the search, adding free searching on Google Scholar, for works published in the English language.

The decision to limit the selection to English-language papers was based on 3 factors. First, the research team possesses proficiency in English, which ensures accurate interpretation and analysis of the included studies. Second, the databases used for literature searches (eg, PubMed) primarily index journals in the English language. Finally, conducting a multilingual review would require significant resources, including translation and verification by native speakers of each language.

There was no date restriction imposed to ensure the capture of all relevant publications related to misinformation on social media in the context of a natural disaster, specifically related to natural hazards. Also, no restriction was imposed on the country or on the age of the target populations.

The search process began with the identification of relevant keywords or phrases that would deliver the desired review results.

A simple search was then done using free text terms which included a search on the topic, looking at words in subject headings, titles, abstracts, and authors' keywords, also scanning for synonyms, alternative spelling variants, acronyms, abbreviations, encompassing (1) "exploded" subject heading, include narrower subject headings found in the hierarchy as free text terms; (2) text mining (subject terms, index terms, descriptors, and MeSH [Medical Subject Headings]); (3) truncation was used where a search for a term that begins with a word was needed; and (4) once all free-text terms and controlled vocabulary terms had been identified, the next step was to use the correct Boolean operators to combine the terms using "or" OR "and."

The three categories of interest were (1) "misinformation" (also "infodemic"), (2) "social media," and (3) "natural disaster" (expanded to include 4 specific types: earthquake, fire, flooding, and tsunami). Combinations of these 3 categories of terms were applied to search titles, abstracts, subject headings, and author keywords. The search strategy also included synonyms, alternative spellings, acronyms, and abbreviations to ensure inclusive coverage of the topic. The review then used the snowballing technique to identify additional studies cited from the studies retrieved.

Peer-reviewed research reports published in journals and conference proceedings were eligible for inclusion. There was no restriction on the date published or the type of original research studies. This included research regarding natural field experiments, observational analysis, surveys, samples, and public information gathered through web scraping and social mining techniques. Systematic reviews meeting the eligibility criteria were examined for additional relevant references.

Inclusion Criteria

Studies were included if the authors only addressed misinformation on social media in the context of a specific instance of a natural disaster.

There was no restriction on the date published or the type of original research studies. This included research regarding natural field experiments, observational analysis, surveys, samples, and public information gathered through web scraping and social mining techniques.

Exclusion Criteria

The studies that did not investigate misinformation on social media in the context of a natural disaster or that were not in English, and duplicates of another paper, were also removed after screening. Also, studies that solely focused on how to design and build tools to detect misinformation were also excluded.

In addition, the exclusion criteria comprised editorials, letters to the editor, systematic reviews, abstracts, protocols, workshop summaries, perspectives, opinions, diagnosis methods, books, and book chapters, as well as summaries of other reviews, which were excluded before further screening. A documented record was kept of the search findings and translated into a PRISMA flow diagram [17] to provide transparent and complete reporting.

Data Extraction (Selection)

We used Microsoft Excel software to capture and synthesize the data. For the included studies, the elements in Tables S2 and S3 found in Multimedia Appendix 1 were analyzed in the full text. The characteristics of the included studies were assessed using a predefined criterion.

XSL•FO
RenderX

Study Characteristics

Each study was analyzed for the demographics, context, geographical location, study methods, objectives, study setting, data analysis techniques, the topic of interest, the period of time, data sources, data size, the collecting data method, misinformation effects, and lessons learned.

Evidence Synthesis

Evidence synthesis includes the type of social media platform, type of natural disaster, type of misinformation, public impact, and who is impacted.

The aim of the study is to (1) critically analyze the available evidence; (2) explore the dynamics of misinformation on social media in the context of natural disasters, shedding light on the challenges, implications, and potential solutions in this critical domain; and (3) the development of a conceptual model linking misinformation, public impact, and natural disasters based on available evidence from the papers sourced.

For the purpose of this review, the term “natural disaster” is used to explicitly refer to natural hazards, including but not limited to hurricanes, earthquakes, floods, tornadoes, and wildfires. The focus on natural hazards allows for a targeted exploration of how misinformation spreads and impacts populations during these specific types of crises.

Also, the conceptual model is obtained from the 9 studies to gain a greater understanding when examining the relationship between misinformation on social media in the context of natural disasters.

Definition of Terms

A disaster, according to the United Nations Office for Disaster Risk Reduction, is: “A serious disruption of the functioning of a community or a society at any scale due to hazardous events interacting with conditions of exposure, vulnerability, and capacity, leading to one or more of the following: human, material, economic, and environmental losses and impacts” [7]. Disasters can be caused by various kinds of hazards [18,19] and can have devastating impacts on people and communities. Disasters linked to natural hazards, including widespread fires, floods, storms, earthquakes, and droughts, may result in significant damage and loss of lives.

Disinformation is commonly defined as false information intentionally shared to deceive [20,21].

Infodemic, which was originally coined by David J Rothkopf in 2003, describes the overabundance of information, including misinformation, associated with significant events such as a federal election, pandemics, or natural disasters [22,23].

Misinformation is defined as the dissemination of inaccurate information without the intention to deceive [20,21].

Public health is the science and practice of preventing disease, extending life expectancy, and promoting overall health through organized societal efforts [24].

Public impact is defined as the influence or effect that actions and events have on the public [25].

Social media is defined as “a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, allowing the creation and exchange of user-generated content” [26].

Results

Overview

Initially, 173 studies were screened for eligibility based on their titles and abstracts, reducing the number of potential studies to 33. Following a full-text review, 9 studies met the inclusion criteria and were included in this narrative review (Figure 1).

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of the search findings.

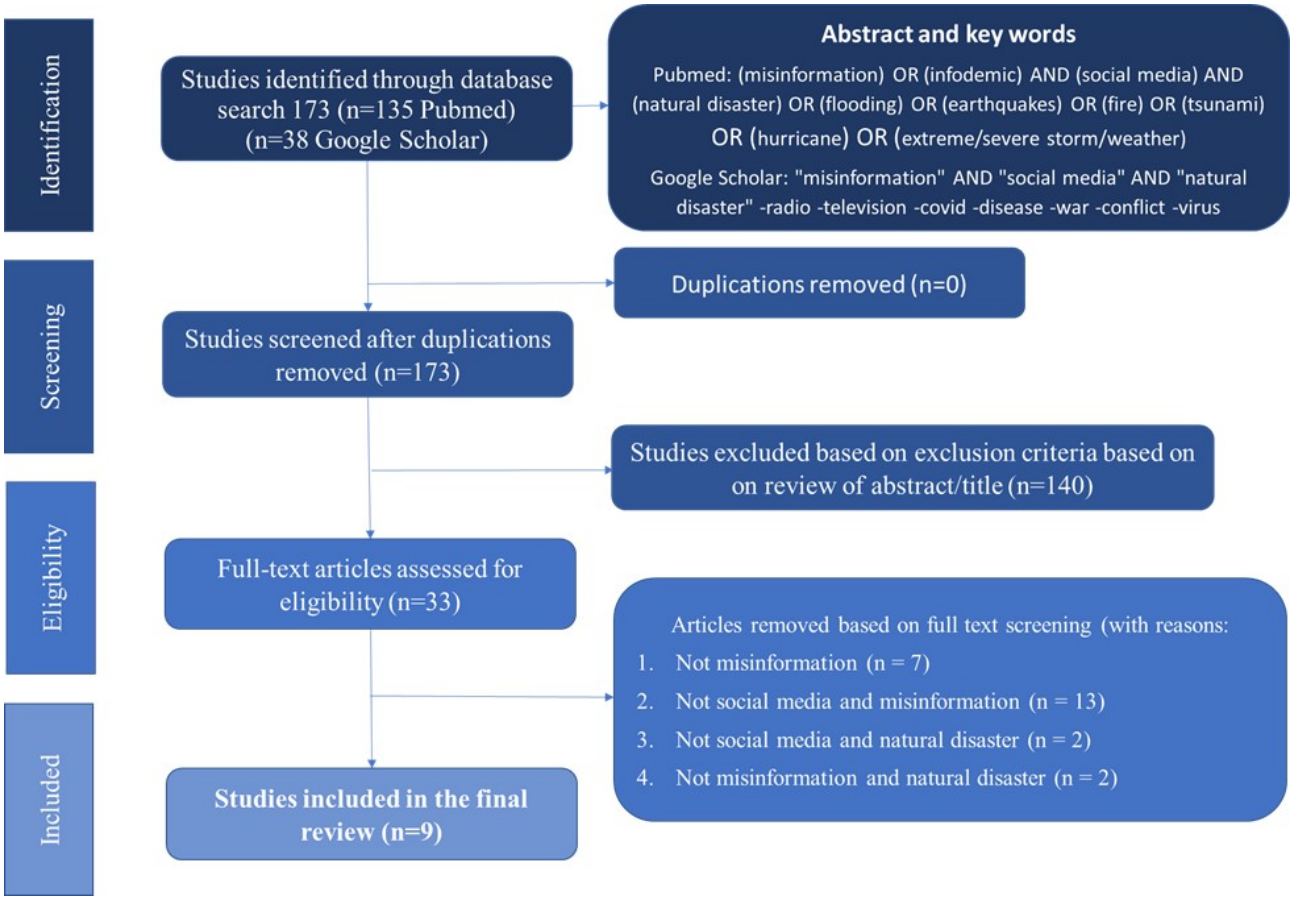

Table 1 summarizes the key characteristics of the 9 studies selected for the review. Of these, 4 studies used a case study design, 4 studies used content analysis, and 1 study used survey methods. All studies analyzed data extracted from social media platforms; 8 studies focused on Twitter, while 1 study examined several social media platforms.

XSL•FO
RenderX

Table . Summary of findings of characteristics of the 9 studies.

Author	Country of origin	Type of study and source	Social media platform	Type of natural hazard (disaster)	Type of misinformation	Study size
Gupta et al (2013) [4]	United States	• Content analysis, • peer-reviewed conference paper	Twitter (subsequently rebranded X)	Hurricane Sandy	Fake images of sharks swimming in the streets and manipulated photos of storm damage.	1.8 million tweets from 1.2 million unique users, with 10,350 tweets containing fake images and 5767 tweets containing real images.
Hunt et al (2020) [5]	United States	Case study, peer-reviewed	Twitter (X)	Hurricanes Harvey and Irma.	False claims that immigration status checks were being conducted at evacuation sites and shelters.	Hurricane Harvey: 2032 unique tweets (1440 debunking tweets). Hurricane Irma: 601 unique tweets (259 debunking tweets).
Vasudevan and Alathur (2022) [6]	India	• Case study, peer-reviewed	WhatsApp and Facebook	Heavy flooding	Misleading information on emergency instructions.	561 completed a survey who were affected by the flood in Kerala.
Rajdev and Lee (2015) [8]	United States	• Thesis: case study, • peer-reviewed conference paper	Twitter (X)	Moore Tornado and Hurricane Sandy	Spam and fake messages.	Collected 1% sample tweets posted during a period of each of the 2 natural disaster events.
Zhai et al (2023) [9]	United States	• Case study, peer-reviewed	Twitter (X)	Hurricane Sandy	False information about the disaster's impact and situation, such as exaggerated damages or incorrect emergency instructions.	691 tweets.
King and Wang (2023) [12]	United States	• Content analysis, peer-reviewed	Twitter (X)	Hurricane Harvey	Misleading information leading to changes in perception.	42 million tweets with 3589 original verified real or false tweets cross-checked with fact-checking websites and relevant federal agencies.
Dallo et al (2023) [13]	Global	• Content analysis peer-reviewed	Twitter (X)	Earthquake	About the ability to predict earthquakes.	82,129 tweets.
Oh et al (2010) [14]	Haiti	• Content analysis, • peer-reviewed conference paper	Twitter (X)	Haiti Earthquake	False claims about aid offers.	962 tweets.
Abdullah et al (2015) [15]	Japan	• Survey peer-reviewed	Twitter (X)	Generically focused	Unverified information and rumors.	133 participants (students from Iwate Prefectural University, Japan).

The narrative review evaluated the available evidence on misinformation via social media in the context of natural disasters and developed a conceptual model to enhance understanding of the intersection of misinformation origin, public impact, and emergency response disruption during natural disasters. The term "natural disaster" is used explicitly to refer to natural hazards, including but not limited to hurricanes, earthquakes, floods, tornadoes, and wildfires. Focusing on

XSL•FO
RenderX

natural hazards enabled a targeted examination of how misinformation spreads and affects populations during these specific types of crises.

Critical Analysis of Available Evidence

The 9 studies reviewed provide powerful insights into how misinformation spreads and the impacts to communities during natural disasters. Synthesizing evidence across key criteria, such as misinformation type and the social media platforms used, reveals distinct challenges posed by different disaster contexts (Multimedia Appendix 1) [4-6,8,9,12,14,15].

Type of Misinformation and Natural Disasters

Recurring themes in disaster-related misinformation include exaggerated reports, misleading emergency instructions, false predictions, and inaccurate information concerning public safety measures. Such misinformation not only disrupts disaster response efforts but also disproportionately affects vulnerable populations. Multimedia Appendices 2 and 3 illustrate the range of disasters examined and the corresponding misinformation trends identified in each case, highlighting the pervasive and far-reaching consequences of misinformation during crises.

Four studies focused specifically on hurricanes [4,5,9,12] and one on Hurricane Sandy and the 2013 Moore Tornado [8]. Two studies focused on earthquakes [13,14], 1 study was generically focused on “disasters” [15], and 1 study focused on the Kerala floods [6].

Social Media Platforms and the Spread of Misinformation

The reviewed studies indicate that misinformation during disasters spreads primarily through popular social media platforms, particularly Twitter (X), Facebook, and WhatsApp.

Twitter was identified by 8 studies as a social media platform for the dissemination of misinformation [4,5,8,9,12-15]. These studies emphasized Twitter’s role in spreading rumors, false predictions, and misleading information during disasters such as Hurricane Sandy, Hurricanes Harvey and Irma, the 2013 Moore Tornado, and the Haiti and Tohoku earthquakes.

Social media platforms like Facebook, WhatsApp, and Twitter are essential for rapid disaster communication, enabling institutions to disseminate critical updates, supporting evacuation efforts, and facilitating resource allocation such as food and medical supplies [6]. For instance, during Hurricane Sandy, social media was crucial for disseminating safety updates [9]; however, these platforms also acted as conduits for misinformation.

The dual role of social media, as both a valuable communication tool and a channel for misinformation, highlights its complex influence on public perception and response efforts [15]. An example of this was seen during the 2018 floods in Kerala, India, where WhatsApp served as the main communication channel for identifying places of safety and communicating the needs of affected individuals. However, this same communication channel was exploited for spreading misinformation, causing confusion and disruption to relief operations [6]. The rapid and unverified dissemination of false information among affected communities contributed to the chaos in relief operations.

The duality inherent in social media highlights the importance of actively monitoring and managing these platforms to ensure they aid rather than hinder disaster response efforts [5].

Impact of Exposure to Misinformation in the Context of a Natural Disaster

Misinformation during natural disasters can profoundly affect the public and disrupt disaster response systems. Vulnerable populations, along with the general public, face heightened risks as misinformation spreads through various sources, including individuals, influencers, bots, and fake profiles, leading to widespread confusion and panic [14,15].

The 9 studies reviewed highlight the rapid and far-reaching consequences of misinformation. Several studies reported associations between misinformation circulating on social media and heightened public panic, perceived misallocation of resources, and a decline in trust in emergency response systems [14]. Public confusion and fear are particularly acute when misinformation distorts the perceived severity of a disaster or spreads false emergency instructions [4,6,8,9,12,14,15].

For example, during Hurricane Sandy, exaggerated reports of damage and incorrect emergency instructions were circulated on Twitter, leading to public confusion and resource misallocation [8]. Similarly, false predictions about earthquakes shared on Twitter triggered panic and disrupted effective response strategies [13-15]. Furthermore, during the Kerala floods, WhatsApp emerged as a major source of misinformation, where false reports about aid and evacuation points delayed relief efforts [6].

In 1 notable instance, misinformation was specifically targeted at immigrant communities. During Hurricanes Harvey and Irma, false claims about immigration enforcement at evacuation sites generated fear and deterred individuals from seeking help [5].

Exposure to conflicting reports and unverified claims makes it challenging for the public to discern credible information, leading to skepticism and diminished trust in authorities and media sources [4].

Multimedia Appendix 4 presents the 3 key themes identified from the 9 studies illustrating the public impact from misinformation during a natural disaster, emphasizing its disruptive effects on trust, resource allocation, and public safety during natural disasters.

The evidence highlights the critical need for robust strategies to combat the spread of misinformation during natural disasters. Suggested approaches include digital literacy campaigns, timely debunking efforts, and coordinated action between governments, social media platforms, and public health organizations. Addressing these challenges is essential for strengthening emergency response systems and restoring public trust in official information.

XSL•FO
RenderX

Dynamics of Misinformation on Social Media in the Context of Natural Disasters

The dynamics of misinformation on social media during natural disasters represent a complex phenomenon that poses substantial challenges while also offering opportunities for targeted interventions. The rapid and widespread dissemination of misinformation endangers public safety and disrupts response efforts, yet it simultaneously highlights the potential for developing tailored mitigation strategies.

In this context, dynamics refers to the evolving interplay between social behaviors, technological mechanisms, and emotional responses that influence how misinformation originates, spreads, and influences public understanding and disaster response. An understanding of these dynamics, including the associated challenges, implications, and potential responses, is essential for designing effective strategies to mitigate the impact of misinformation and improve disaster resilience.

Challenges

The role of AI in misinformation management is inherently bidirectional. On one hand, algorithmic tools can detect and counter false information, while on the other hand, social media content algorithms often prioritize engagement over accuracy, curating personalized news feeds that amplify sensational content. As a result, misinformation, particularly that which evokes strong emotional responses, often receives greater visibility than verified information [5]. Platforms such as Twitter, Facebook, and WhatsApp facilitate the rapid sharing of sensational or emotionally charged, easier-to-read content and tend to resonate more with users experiencing stress during disasters. The emotional resonance contributes to the accelerated spread of misinformation [4]. The speed and volume of such content can overwhelm emergency communication channels, confuse the public, and erode trust in official sources [5,8,9,14].

Furthermore, the decentralized nature of social media allows anyone to act as a source of information, regardless of credibility. This absence of gatekeeping makes it difficult for the public to distinguish between trustworthy sources and those spreading misinformation. The resulting confusion can lead to panic, as evidenced during Hurricane Sandy and the Kerala floods, where false reports led to delayed relief efforts [4,6,8].

The influencers, users with a substantial social media following, exacerbate the problem. During the 2013 Moore Tornado, high-profile accounts were responsible for the spread of misinformation, which misdirected resources and heightened public confusion [8].

Compounding these structural issues is the psychological environment of disaster contexts. Zhai et al [9] observed that emotionally charged misinformation is more likely to resonate with fearful and uncertain audiences. This resonance increases the likelihood of misinformation being shared, creating a feedback loop in which it spreads rapidly and becomes increasingly more difficult to debunk.

These dynamics highlight the complexity of misinformation during disasters and the critical importance of regulating influential content sources, strengthening digital literacy, and enhancing platform accountability.

Implications

The consequences of misinformation during natural disasters are immediate and far-reaching. It not only causes immediate confusion and panic but also delays emergency responses and undermines long-term trust in official information sources. These effects persist well beyond the disaster itself. When the public is exposed to conflicting or inaccurate information during a disaster, their trust in future communications is diminished, making it more difficult for authorities to manage subsequent emergencies effectively [13,27].

As noted by Dallo et al [13], this erosion of trust weakens community cohesion and reduces collective disaster resilience. When public trust deteriorates, communities are less able to respond in a unified and effective manner, potentially leading to greater societal fragmentation and reduced capacity to withstand future disasters [28]. These outcomes highlight the importance of sustained efforts to build and maintain public trust in official communications during disasters.

Additionally, misinformation released during disasters can lead to misallocation of resources, inappropriate public behavior, and delayed emergency response. When individuals act on misinformation, such as evacuating in response to nonexistent threats or requests for aid in areas not requiring immediate need, emergency services can become overwhelmed [4,6,12]. For instance, Rajdev and Lee [8] reported how misinformation during Hurricane Sandy misled the public into taking misguided actions, which strained emergency resources and complicated the overall response effort. In such cases, disaster management teams must contend not only with the crisis but also with the secondary challenges created by misinformation.

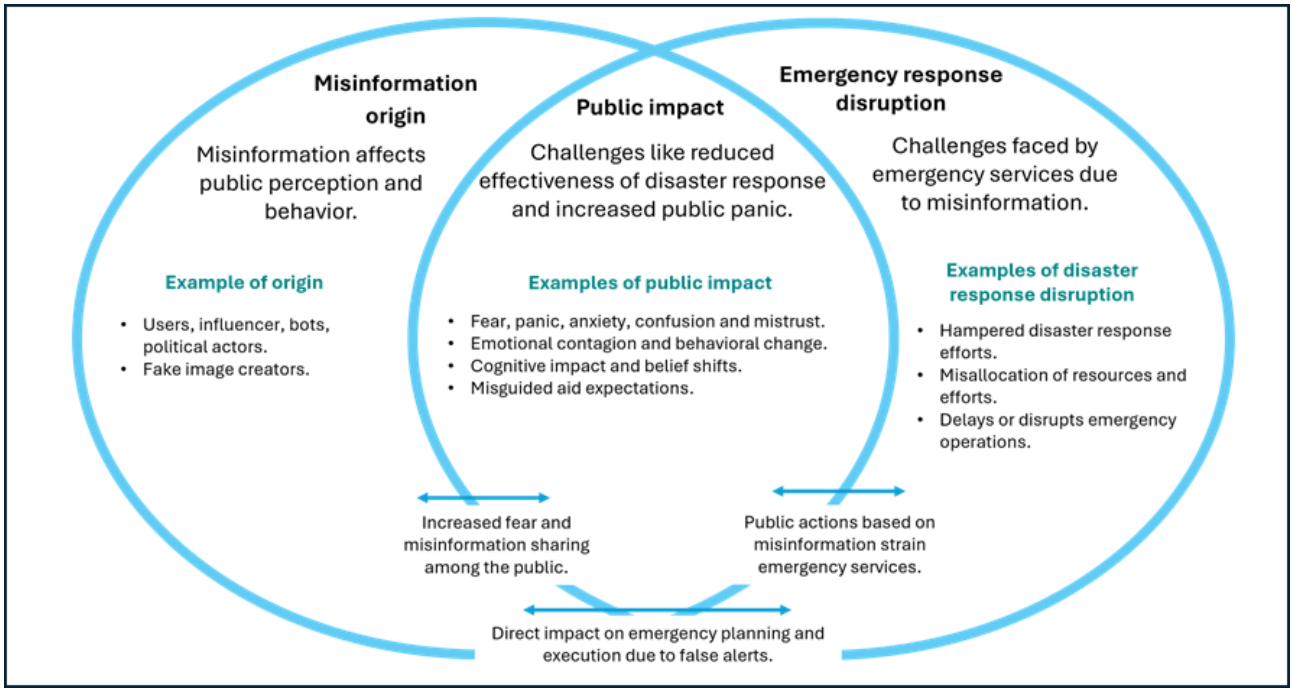
Potential Solutions

Addressing the challenges posed by misinformation during natural disasters requires a multipronged approach. One key solution involves the use of advanced technological tools, such as AI algorithms, to detect and flag misinformation on social media platforms. These systems can identify patterns of misinformation and alert both users, official agencies, and platform administrators, enabling timely corrective action [5,9,14]. Additionally, partnerships with fact-checking organizations allow social media platforms, social media platforms to implement real-time verification mechanisms, which can help curb the rapid spread of unverified content [14].

Public education also plays a crucial role in countering misinformation. Digital literacy programs that teach individuals how to assess the credibility of online content can reduce susceptibility to misinformation during disasters. Such programs should emphasize critical thinking and promote awareness of the risks associated with sharing unverified information [8,14,29]. Furthermore, targeted educational campaigns aimed at specific demographics, such as older adults, who are more likely to unknowingly spread misinformation, can be particularly effective [13].

XSL•FO
RenderX

Moreover, collaboration between governments, social media platforms, and public health institutions is essential. Through strategic partnerships, these entities can coordinate the dissemination of timely, verified information during disasters [4,6]. Such collaborations should prioritize amplifying credible sources and adjusting platform algorithms to promote accurate information over sensationalized or misleading content. Furthermore, proactive engagement such as preemptive debunking and real-time updates during a disaster can help to limit the spread and influence of misinformation [5,9,14,30].



Communication strategies must also account for the emotional responses that misinformation can trigger during disasters. Understanding the emotional dynamics within affected communities enables the development of messages that are empathetic, clear, and trustworthy. This approach can help reduce panic and confusion while reinforcing public trust in official sources. For example, during the Kerala floods, misinformation shared via WhatsApp contributed to widespread anxiety and disrupted relief efforts [6]. Emotionally sensitive communication may alleviate distress and enhance the overall effectiveness of disaster response.

Finally, predisaster preparedness initiatives should include public education about misinformation and promote critical thinking before a natural disaster occurs. Programs such as community disaster preparedness events can inform the public about the dangers of misinformation and encourage reliance on official communication channels [13]. The proactive awareness campaigns are vital for ensuring that individuals are better equipped to navigate the complex information landscape during disasters, thereby strengthening societal resilience and reducing the harmful impact of misinformation.

Conceptual Model Linking Misinformation, Natural Disasters, and Public Impact

The research findings underscore the multifaceted impact of misinformation on natural disasters and the public. The conceptual model presented in Figure 2 [4-6,8,9,12,14,15], structured as a Venn diagram, offers a systematic framework that has been largely absent in existing literature. It elucidates the complex interrelationships between the origins of misinformation, its effects on public perception, and the resulting disruptions to emergency response systems during disasters.

Figure 2. Conceptual model extrapolated from the 9 studies, illustrating how misinformation on social media impacts the public and disrupts disaster recovery.

The conceptual model synthesizes findings from the 9 included studies, organized into 3 interrelated domains: misinformation origin, public impact, and emergency response disruption. Each domain was examined through extraction and thematic analysis of study-level data, enabling the identification of key patterns related to misinformation actors, societal reactions, and institutional challenges (Figure 2).

By illustrating the intersections and overlaps between the domains, the model highlights the compounding effects of misinformation in disaster contexts, demonstrating how these dynamics escalate challenges and increase the burden on response systems [1].

The interconnected nature of these concepts suggests that efforts to identify and address misinformation at its source may enhance public health outcomes and improve disaster response effectiveness.

While misinformation is typically unintentional, in the context of natural disasters, it may be amplified by coordinated disinformation campaigns, automated bots, or actors with strategic intent. This convergence increasingly blurs the distinction between misinformation and disinformation.

XSL•FO
RenderX

Misinformation Origin

Misinformation during emergencies often originates from a range of sources, including ordinary users, social media influencers, bots, and fake accounts [4,5,13-15]. Ordinary users may unknowingly share unverified or manipulated content, often motivated by a sense of urgency or a desire to inform others [31]. Influencers, driven by the pursuit of attention and engagement, may amplify misinformation due to its sensational or emotionally resonant nature. In contrast, bots and fake accounts are typically programmed to deliberately spread false information with the intent to create confusion and panic [21,27]. These actors contribute to a feedback loop, whereby misinformation gains visibility and traction, becoming increasingly difficult to correct once it has spread widely [32].

Additionally, the design of social media platforms, which prioritizes immediacy and engagement, plays a pivotal role in the amplification of misinformation. Content such as exaggerated reports of disaster severity, false safety procedures, or fabricated health advisories often spreads more rapidly than verified information from official sources [28,32,33].

Algorithms that prioritize engaging content over factual accuracy contribute significantly to this phenomenon [5]. Zhai et al [9] demonstrated how social network dynamics and sentiment contagion fuel the spread of misinformation, particularly in emotionally charged disaster contexts. Rapid content sharing without verification contributes to what is referred to as a misinformation cascade, making it challenging for the public to distinguish between accurate and false information.

Users often place trust in their personal networks for disaster-related updates, assuming credibility based on social proximity rather than content accuracy. The misplaced trust exacerbates the problem. During Hurricane Sandy, for example, exaggerated reports of damage and doctored images circulated widely on social media, causing unnecessary fear and panic [4,8].

As misinformation spreads, it creates confusion and panic, directly undermining the effectiveness of official communication channels during disasters [4,6,8,9,12-15]. It misguides public behavior and erodes trust in official communications, thereby complicating disaster response efforts [6,13]. The convergence between misinformation origin and its public impact reveals the challenge of maintaining public trust and ensuring effective communication during disasters [8].

Public Impact

The societal and psychological effects of misinformation during disasters are profound. The misinformation distorts public perceptions, leading to confusion and inappropriate actions, such as unnecessary evacuations or ignoring official guidance [9]. This confusion, compounded by the public's increasing reliance on social media for real-time updates, erodes trust in credible information and reduces compliance with official instructions [5,13].

The resulting behavior shifts, driven by misinformation, can delay coordinated disaster responses, misallocate resources, and undermine the overall effectiveness of emergency operations [6]. Dallo et al [13] similarly observed, stating that misinformation generates widespread confusion and fear among the public, significantly impeding disaster management efforts.

As reliance on social media increases, distinguishing between verified and false information becomes increasingly difficult, further diminishing public trust and adherence to official directives [5]. The erosion of public trust weakens effective communication and coordination during disaster response, contributing to fragmented and delayed decision-making [4-6,8,12-15].

Heightened emotional states during crises amplify the damaging effects of misinformation, destabilizing already fragile situations. For instance, during Hurricane Sandy and the 2018 floods in Kerala, misinformation fueled public confusion and anxiety, disrupting emergency responses and delaying critical relief efforts [6,8].

Moreover, beyond immediate operational challenges, the long-term mental health consequences of exposure to misinformation are significant. Anxiety, depression, and posttraumatic stress disorder may arise when receiving misinformation about the safety of affected areas or the availability of essential resources, placing further strain on mental health services [6,34,35].

The intersection between public impact and emergency response disruption becomes evident in the actions of misinformed individuals. Fueled by misinformation, public behaviors such as confusion, panic, and inappropriate actions directly undermine the efficacy of official communications and disaster response strategies [4,9,13]. These actions not only hinder response coordination but also lead to the misallocation of resources, ultimately reducing the effectiveness of emergency operations [6].

Emergency Response Disruption

While social media serves as a vital tool for crisis communication, it simultaneously poses significant challenges to emergency response operations. The rapid spread of misinformation can saturate communication channels, misdirect resources, and create false alerts, all of which complicate coordination and operational effectiveness [9,12,14].

Emergency responders are frequently forced to simultaneously manage both the actual disaster and counteract the spread of misinformation. This dual burden diverts attention and resources from where they are most urgently needed, thereby weakening the overall emergency response effort [6,9,12,14,15].

Disruption in resource deployment further complicates crisis management, particularly when misinformation about aid availability, safe zones, or evacuation procedures leads to confusion and misallocation. Events such as earthquakes and hurricanes have demonstrated how such misinformation delays relief efforts and overwhelms emergency services [6,9]. As responders are required to counter misinformation while managing real-time emergencies, operational delays become inevitable [6,8,9,12]. Compounding the problem is the speed at which misinformation spreads, often outpacing official corrections, making debunking efforts an ongoing challenge

XSL•FO
RenderX

[4,5]. Hunt et al [5] observed that the effectiveness of debunking strategies is heavily dependent on both the timing and platform used. When corrective messaging lags, public safety is undermined and trust in emergency services erodes [9,14,15].

The interplay between misinformation origin, public impact, and emergency response disruption highlights the compounded challenges misinformation creates during disasters. As illustrated in Figure 2, the domain overlap reinforces a feedback loop showing how misinformation alters public behavior, amplifies panic, and disrupts emergency response operations, collectively degrading the effectiveness of crisis management and compromising public safety. Addressing these challenges requires robust mechanisms to combat them. Governments, social media platforms, and relevant organizations must collaborate to enhance public awareness, refine communication strategies, and build public resilience against misinformation. By understanding how misinformation spreads and impacts both the public and emergency services, more effective interventions can be developed to strengthen disaster resilience and improve public health outcomes.

Discussion

Principal Findings

The narrative review has critically evaluated the spread of misinformation on social media in the context of natural disasters, shedding light on key challenges, implications, and potential solutions.

A conceptual model was developed to illustrate the interconnected relationships between misinformation origin, public impact, and disaster response, grounded in evidence from the 9 reviewed studies.

The main findings reveal the dual role of social media during disasters; while facilitating the rapid dissemination of vital information, they also serve as a vector for misinformation. The speed and scale at which the misinformation spreads can undermine official communication efforts, create public confusion, disrupt disaster resilience, hinder public health efforts, and divert critical emergency resources [6,35]. Several studies reported cases in which misinformation regarding aid availability and safe locations led to unnecessary chaos, overwhelming emergency services, and delayed assistance to those in need [6,8,12,36]. When the public perceives official sources as unreliable or slow, they increasingly turn to unofficial and less credible alternatives, heightening the risk of acting on misinformation [28].

Additionally, the erosion of trust in official communications weakens community resilience [14] and has psychological implications that extend beyond the immediate disaster response. Exposure to misinformation has been associated with long-term mental health impacts, including anxiety, stress, and posttraumatic symptoms, especially when the public is misinformed about safety conditions or resource availability [4,37].

Addressing this duality requires a deep understanding of the origins of misinformation, its public impact, and its capacity to disrupt disaster response systems.

The 3 interconnected concepts—misinformation origin, public impact, and emergency response disruption—emerged across the studies and informed the development of the conceptual model (Figure 2). By illustrating the overlap between these domains, the model provides a structured framework for understanding how misinformation disrupts public health, emergency response effectiveness, and disaster resilience.

Misinformation during disasters originates from a variety of sources, including ordinary users, influencers, and bots [4,6,13-15]. While some share content with good intentions, others, particularly influencers, can unintentionally amplify false narratives due to their large followings [6,9,12,13,38]. Automated bots further exacerbate the problem by generating and spreading misinformation that appears legitimate through tactics such as hashtag hijacking and the use of official links, as observed during the 2013 Moore Tornado [8].

The rapid spread of misinformation is driven in part by the algorithmic architecture of social media platforms, which prioritizes engagement-based content (shares, likes, and comments) over accuracy [5]. This environment facilitates the viral dissemination of misinformation, contributing to heightened stress, confusion, anxiety, and public panic [5,35].

Numerous studies confirm the detrimental effects of misinformation on public well-being during disasters. When individuals receive conflicting reports, their trust in official sources diminishes, leading to heightened emotional responses and behavior that undermines response efforts, such as unnecessary evacuations or disregard for safety protocols [4,5,14,35]. Events like Hurricane Sandy and the Kerala floods exemplify how misinformation and increased public anxiety eroded trust in official communications and complicated relief operations [4,6,8].

The misallocation of resources is another consequence of misinformation. False alerts have repeatedly caused emergency services to divert attention to noncritical areas, delaying vital assistance elsewhere.

For instance, during Hurricane Sandy and the 2013 Moore Tornado, misinformation about resource availability misled responders and complicated coordination, while during the Kerala floods, false data led to misdirected relief operations [4,6,8,9,36]. These disruptions illustrate how misinformation not only undermines immediate disaster response efforts but also impairs longer-term coordination and recovery. The psychological burden faced by affected populations is further intensified when community recovery is delayed due to the diversion of resources and persistent misinformation [36].

From the evidence, several lessons emerge. First, the speed of the misinformation spread necessitates proactive and timely countermeasures. Once misinformation gains traction, it often outpaces correction efforts, causing widespread harm. Real-time debunking campaigns led by trusted authorities must be prioritized and well-resourced to counteract this effect [8,9,14].

XSL•FO
RenderX

Communication strategies must also emphasize accuracy, clarity, and empathy to rebuild public trust [6,14,39].

Second, public education is vital. Preemptive educational initiatives that promote digital literacy and critical thinking can empower individuals to evaluate online information and reject misinformation [8,14,40]. These campaigns should target all demographics, including vulnerable groups such as older adults who are more susceptible to false narratives [13]. By fostering media literacy, these campaigns can reduce the spread of misinformation and enhance public resilience [14,41].

Third, technological advances should be leveraged. AI detection tools for real-time verification can identify patterns and flag or remove misinformation before it spreads widely [12,42]. These technologies must be integrated into disaster communication systems to enhance responsiveness and limit harm.

Early intervention is critical. Rapid deployment of countermeasures can contain the spread of misinformation and reduce its impact. Delayed responses, by contrast, allow false narratives to proliferate, compounding the damage [8,9].

To conclude, future efforts must focus on a combination of proactive strategies, technological innovation, and public education to effectively combat the challenges posed by misinformation during disasters. Disaster preparedness plans must formally integrate management of misinformation as a key component, ensuring that emergency responders are equipped to swiftly identify and address false narratives.

The discussion should be interpreted in light of the narrative review's strengths and limitations.

Strengths

A notable strength of this narrative review lies in its robust and transparent methodological framework, which adheres to the established guidelines from the Joanna Briggs Institute and the Cochrane Handbook for Systematic Reviews. The rigorous observance of PRISMA guidelines further ensures methodological transparency, enhancing the reliability and reproducibility of the findings.

Additionally, this review synthesizes evidence from a diverse array of studies, incorporating data from different geographic regions and varied natural disaster contexts. By not imposing date restrictions, this paper captures a broad temporal perspective, allowing for an inclusive assessment of the evolving dynamics of misinformation on social media during natural disasters.

Furthermore, the conceptual model developed in this narrative review advances the literature by illustrating the complex interrelationships between misinformation origins, public impacts, and disruptions to emergency response systems.

Limitations

There may be several limitations of the narrative review.

- The retrieved results included only the studies that were indexed in PubMed or found in a free search on Google Scholar. Thus, any studies not indexed on these sites were excluded from the review.
- The selection of search terms might not have been sufficiently comprehensive to capture all existing literature on misinformation on social media during natural disasters.
- The review did not examine narrative, social, and other theories posed as reasons for the spread of the misinformation.
- Language restrictions to English-only studies may limit the generalizability of the findings.

Conclusions

This narrative review critically examined the role of misinformation on social media during disasters, specifically natural hazards, highlighting its challenges, implications, and potential solutions. The review highlights the pervasive and damaging impact of misinformation, including its disruption of disaster response, erosion of public trust, and amplification of psychological distress. The conceptual model developed (Figure 2) provides a structured framework to deepen understanding of these interconnected dynamics.

The findings also demonstrate the complex, dual role that social media plays during disasters. While it facilitates the rapid dissemination of vital information, it simultaneously acts as a breeding ground for misinformation. The speed and scale at which misinformation spreads can undermine official communications, erode public trust, and create confusion and anxiety. These disruptions not only compromise disaster resilience but also hinder the effectiveness of emergency response systems and degrade public health outcomes, as illustrated by the conceptual model.

Moving forward, proactive strategies, technological innovation, and public education must be prioritized. This includes integrating misinformation management into disaster preparedness plans, enhancing public awareness, deploying advanced verification tools, and fostering trust in credible sources. By combining these approaches, individuals and communities will be better equipped to navigate the challenges posed by misinformation, thereby strengthening disaster resilience and improving public health outcomes.

In addition, future research, currently limited in scope, should focus on the following areas.

- A clearer understanding of the current state of misinformation during natural disasters.
- The experiences and perspectives of public health and disaster response professionals, particularly how misinformation affects roles, decision-making, and the effectiveness of response strategy.
- Emotional and psychological dimensions of misinformation in the context of natural hazards.

Ongoing research and policy efforts are critical for refining disaster preparedness and ensuring that future disaster responses are not compromised by the harmful effects of misinformation.

Abstract

Background: Social media is a prominent way in which health information is spread. The accuracy and credibility of such sources range widely, with misleading statements, misreported results of studies, and a lack of references causing health misinformation to become a growing problem. However, previous research on health misinformation related to topics including vaccines, nutrition, and cancer has excluded physical activity despite it being highly searched for and discussed online.

Objective: This systematic review was designed to synthesize the existing literature focused on physical activity misinformation on social media in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines.

Methods: Keyword searches were conducted in PubMed, the Cochrane Library, Web of Science, and Scopus databases for records published between January 2016 and May 2025. This search strategy yielded 9039 articles. Titles and abstracts were screened by independent reviewers, resulting in 168 (1.86%) articles selected for full-text review. After further review, 33 (19.6%) articles met the inclusion criteria and were used in the final synthesis.

Results: For the 33 studies selected, topics included physical rehabilitation and therapeutic exercise recommendations (n=15, 45%), general physical activity and messaging (n=6, 18%), exercising with a specific condition (n=4, 12%), women's health (n=3, 9%), weight loss (n=2, 6%), exercise testing (n=1, 3%), "immune boosting exercise" (n=1, 3%), and workplace sitting versus standing guidelines (n=1, 3%). The social media platforms YouTube (n=13, 39%), TikTok (n=7, 21%), Facebook (n=2, 6%), Instagram (n=1, 3%), and Pinterest (n=1, 3%) were studied, whereas other articles (n=9, 27%) analyzed content that had not explicitly been posted to social media but could be shared widely online. In total, 4 (12%) studies reported research that proactively engaged participants, and the remaining 29 (88%) studies analyzed readily available online content, including social media, news articles, websites, and blogs. Furthermore, 27 (82%) studies reported at least 1 measure of misinformation prevalence, whereas 21 (64%) reported a metric of reach, and 6 (18%) studies reported a measure of misinformation spread.

Conclusions: Our findings indicate that research on social media physical activity misinformation spans a diverse array of physical activity topics, with YouTube being the most studied platform due to its widespread use and ease of content evaluation. This review also highlights the prevalence of low-quality information across various platforms and a lack of longitudinal investigations. Our review underscores the need for multifaceted research approaches and suggests several strategies to combat misinformation, including improved messaging, high-quality information dissemination by institutions, detailed debunking efforts, and raising awareness about misinformation. Future research should focus on understanding the spread of physical activity misinformation across platforms and its impact, especially on vulnerable populations.

Introduction

Background

It is well documented that the internet is a key source of health information for many people across the world [1,2]. Although websites, blogs, and social media can provide valuable information about both general and specific health topics [3,4], they can just as easily present misleading or inaccurate information [5,6], termed misinformation. Misinformation is often shared unintentionally by parties unaware of its falsehood, contrasting with disinformation, which is shared with an awareness of its falsity and potential harm [7]. The dissemination of misinformation can be carried out by various actors, including public figures, professionals, educators, and personal contacts.

Although misinformation spans many domains, the realm of physical activity is notably susceptible. Misinformation regarding the safety and benefits of physical activity, particularly newer trends, such as high-intensity interval training (HIIT), can lead to misconceptions about its safety and potential risks, impacting public health guidance and individual behavior [8]. The ubiquitous use of smartphones and social media exacerbates the speed and reach of such misinformation [9], highlighting the urgency to address it specifically within the broader context of health misinformation.

The issue of online health misinformation has become so significant that in 2021, the US surgeon general issued an advisory guiding stakeholders (from individuals to organizations) on actions to combat misinformation [10]. For researchers taking action, the advisory recommends to (1) strengthen the monitoring of health questions, concerns, and misinformation; (2) assess the impact of health misinformation; (3) prioritize understanding how people are exposed to and affected by misinformation and how this may vary for different subpopulations; and (4) evaluate the effectiveness of strategies and policies to prevent and address health misinformation. This work is well underway, as several systematic reviews have been conducted to identify the range and impact of health information research [4,11,12] as well as methods to correct health misinformation on social media [13].

The wide range of health misinformation topics that have been investigated on social media includes pandemics, nutrition, and cancer [4,11,12]. Findings from the study by Suarez-Lledo and Alvarez-Galvez [12] showed that most health-related misinformation research has focused on vaccines and drugs or smoking, with Twitter having the highest prevalence of misinformation across the health topics and platforms investigated. Melchior and Oliveira [11] found that the prevalence of misinformation in health topics reported by studies ranged from none to 98%. This variance in the prevalence of health misinformation on social media is concerning and indicates why this is a growing field of study. Between 2012 and 2018, an 850% increase in published articles was reported, from 2 to 19 published annually on the topic [12].

However, one area that has received limited attention is physical activity misinformation. Despite the interest in health-related misinformation and the well-established benefits of regular physical activity for health and well-being [14], there is still a significant amount of misinformation surrounding this topic online. This is particularly concerning given the importance of physical activity in preventing and managing chronic conditions, such as obesity, diabetes, and heart disease [15]. Although physical activity is generally viewed as safe, there are established, elevated risks of adverse events caused by increasing physical activity while striving to meet public health guidelines [16] and participating in exercise interventions [17], with musculoskeletal injuries being among the most common adverse events—more so among higher intensity exercises [18]. Ekkekakis et al [8] have brought attention to myriad unfounded claims regarding the safety and tolerance for higher intensity physical activity (specifically, HIIT). Extraordinary claims have been made in reference to HIIT, and it is sometimes ignored that HIIT can contribute to injury and adverse cardiovascular events, among other negative consequences. Therefore, it is crucial to understand the prevalence and impact of physical activity misinformation and develop effective strategies to combat it.

Objective

The purpose of this systematic review was to explore the current state of research on physical activity misinformation on social media, including its reported prevalence, reach, and spread, and strategies for addressing this issue.

Methods

Guidelines and Search Strategy

The protocol for this systematic review was preregistered on PROSPERO (CRD42022316101). The procedure and research findings have also been reported in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [19], see Multimedia Appendix 1. To review the existing literature of physical activity misinformation on social media, we searched the databases PubMed, the Cochrane Library, Web of Science, and Scopus for records published from January 2016 through May 2025, using keywords related to misinformation, social and online media, information transmission, and physical activity. This time frame was selected because research on social media health misinformation shows little scholarship before 2016 [12].

XSL•FO
RenderX

Furthermore, Google Search trends showed interest in "fake news," and by proxy, the idea of misinformation increased dramatically between October 2016 and February 2017, coinciding with the 2016 US presidential election [20].

Adapting the search strategy of Wang et al [4], our search was structured around four key concepts to ensure comprehensive coverage: (1) misinformation terms, including synonyms such as "health myths" and "inaccurate information," to capture various forms of information disorders; (2) social media and online platforms to cover a wide range of digital dissemination channels; (3) information transmission terms to identify studies examining the spread and engagement with content; and (4) physical activity terms, including a broad array of activities and exercise types. Medical Subject Headings (MeSH) were used, where possible, to enhance search sensitivity and precision, as presented in Textbox 1.

Textbox 1. MeSH used in this study.

((misinformation OR disinformation OR "fake news" OR rumor* OR myth* OR "false claims" OR "inaccurate information" OR "misleading information" OR "unsubstantiated claims" OR "health fraud" OR pseudoscience OR fallacy) OR "Communication"[MeSH] OR "Disinformation"[MeSH]) AND ((online OR internet OR social media OR web OR website OR blog* OR forum* OR Twitter OR X OR Facebook OR Instagram OR TikTok OR Snapchat OR YouTube OR Reddit OR Pinterest OR Google OR "search engine" OR "social network*" OR "online community" OR "digital media") OR "Social Media"[MeSH] OR "Internet"[MeSH]) AND ((spread OR propagat* OR disseminat* OR circulat* OR communicat* OR diffus* OR broadcast* OR share OR sharing OR viral* OR dissemination OR transmission OR reception OR engagement OR amplification) OR "Information Dissemination"[MeSH]) AND (("physical activity" OR exercise OR "aerobic exercise" OR "aerobic training" OR "strength training" OR "resistance training" OR fitness OR sport* OR recreation OR "active lifestyle" OR "exercise therapy" OR "physical fitness" OR walking OR running OR swimming OR cycling OR yoga OR "weight lifting") OR "Exercise"[Mesh] OR "Physical Fitness"[Mesh] OR "Resistance Training"[Mesh])

The search yielded 4424 records from PubMed, 238 records from the Cochrane Library, 517 records from Web of Science, and 4041 records from Scopus. All collected references were uploaded into reference management software Zotero (version 7.0; Corporation for Digital Scholarship) for deduplication and subsequent assessment of eligibility. Of the 9220 records, we identified and removed 184 (2%) duplicate records, leaving 9036 records to be reviewed for eligibility. By hand searching, we identified a further 3 records to screen, bringing the total to 9039 records.

Screening and Study Selection

The full list of unique articles was downloaded from the reference management software and organized in a spreadsheet (Microsoft Excel version 16.0), which was screened by 2 research team members independently for relevance based on title, abstract, and keywords. The inclusion and exclusion criteria mentioned in Textbox 2 were used.

Textbox 2. Inclusion and exclusion criteria for article selection.

Inclusion criteria

- Misinformation: Articles must relate to misinformation, disinformation, or another information disorder.
- Social media: Potential misinformation must be actually or plausibly shared or consumed through social media (eg, an original social media post or sharing an online news article on social media).
- Physical activity: Only articles related to physical activity and exercise were included.
- Other article restrictions: Articles must concern humans sharing or consuming information about human physical activity. Articles must be peer-reviewed original research. Only articles written in English were included.

Exclusion criteria

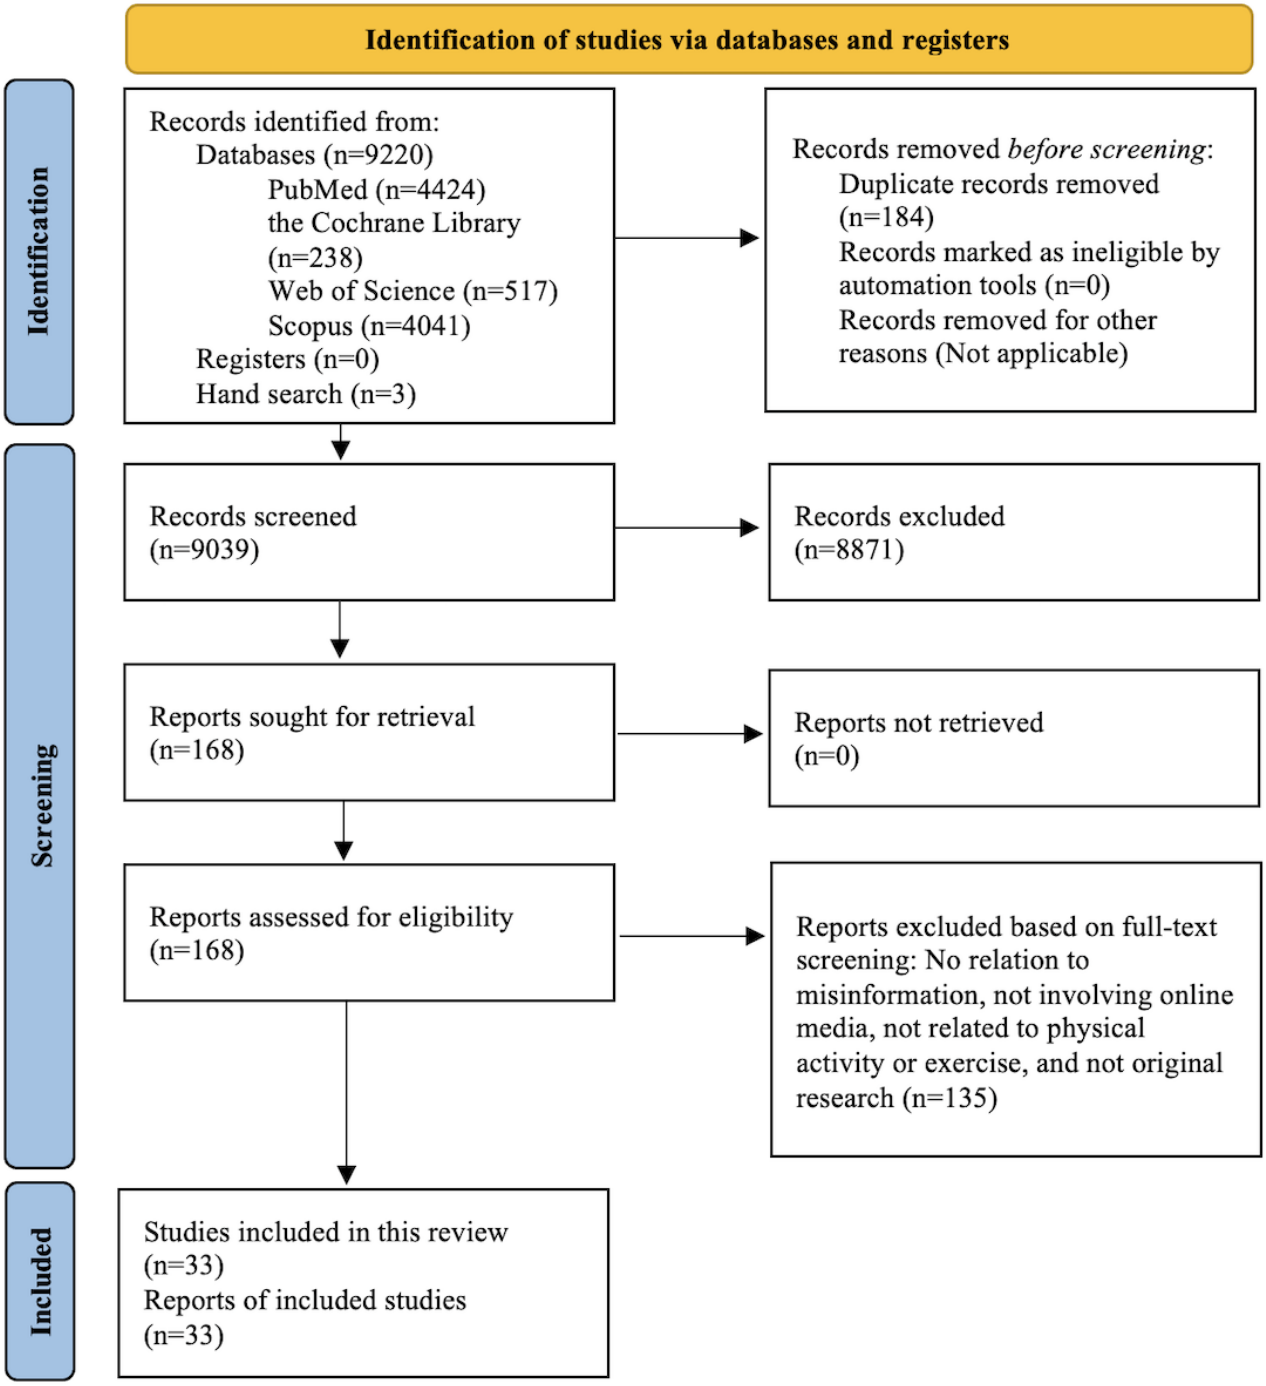
- Reviews, editorials, and gray literature (eg, government reports, policy papers, and dissertations) were excluded.

Upon screening, 168 articles were considered potentially eligible and were marked for full-text review. After reviewing the full articles, 33 (19.6%) articles were found to satisfy all inclusion criteria.

Data Extraction and Analysis

Following screening, the 33 eligible studies were analyzed for the following information: (1) physical activity topic; (2) social media platform and media type; (3) study population and design; and (4) quantification of misinformation prevalence, reach, and spread. Our plan was to conduct quantitative and qualitative data analyses on the final sample of 33 studies to identify and summarize common themes and measures of physical activity misinformation. While we initially planned to conduct statistical analysis and formal quality assessment of the included studies, heterogeneity in study designs and outcomes reported made this unfeasible, and substantial modifications to standard quality assessment tools would have compromised their validity.

Results



Physical Activity Topics

In the 33 studies selected during screening (Figure 1), the most common topic was the quality and accuracy of physical rehabilitation and therapeutic exercise recommendations (n=15, 45%). Other significant categories included physical activity misinformation pertaining to general physical activity and messaging (n=6, 18%), exercising with a specific condition (n=4, 12%), women's health (n=3, 9%), and weight loss (n=2, 6%). The remaining studies addressed misinformation

XSL•FO
RenderX

concerning exercise testing (n=1, 3%), "immune boosting exercise" (n=1, 3%), and workplace sitting versus standing guidelines (n=1, 3%). Table 1 presents the characteristics of the included studies.

Social Media Platform and Media Type

In the 33 studies, the most studied social media platform, YouTube (n=13, 40%), was used to evaluate the content quality and accuracy of 1060 videos. Similarly, TikTok was used in 7 (21%) studies to analyze the content of 1046 videos. Facebook (n=2, 6%) was the third most common platform included in the relevant studies, with 364 participants interacting with Facebook posts or describing their use of Facebook groups for information. Pinterest was used in one study, in which the content of 234 "pins" was analyzed for misinformation. The final social media platform included was Instagram (n=1, 3%), in which 495 posts from 33 prominent accounts (ie, influencers), with an average of more than 1 million followers, were evaluated. All other selected studies (n=9, 27%) used digital media that could be shared on social media, as opposed to content already shared on social media platforms. This included blogs, news articles, internet forums, or other online resources found from Google searches.

Study Population and Design

Regarding the study populations and designs, four (12%) of the 33 studies involved data collection with human participants: (1) determining what college students (n=340) perceive as credible health information on Facebook [23]; (2) designing a module trial to train college students (n=149) on how to critically assess potentially misleading weight loss information online [26]; (3) assessing the believability of exercise blogs among young women (n=141) [35]; and (4) surveying breastfeeding women (n=24) for potential sources of misinformation, including Facebook groups [31]. The remaining 29 (88%) studies did not consist of actively recruited participants but analyzed readily available online content, including social media, news articles, websites, or blogs. Aside from observational study design (content analysis), the other study designs used were experimental, educational, and qualitative (using semistructured interviews).

Prevalence, Reach, and Spread

We considered the measurement of misinformation in terms of prevalence (frequency among content), reach (how many individuals saw the content), and spread (whether the content was disseminated; Multimedia Appendix 2 [21-53]). A total of 27 (82%) of the 33 studies reported a measure of misinformation prevalence, the most common of which was video content quality, assessed using the Global Quality Score (GQS)—a tool to measure educational quality of online health-related content, with scores ranging from 1 (very poor quality) to 5 (excellent quality)—and DISCERN [54], an instrument for judging the quality of consumer health information on treatment choices, with scores ranging from 63 to 75 indicating excellent quality, 51 to 62 indicating good quality, 39 to 50 indicating fair quality, 27 to 38 indicating poor quality, and 16 to 26 indicating very poor quality, or 4 to 5 indicating high quality, 3 indicating moderate quality, and 1 to 2 indicating low quality for the modified DISCERN instrument [55].

Of the 33 studies, 12 (36%) studies using GQS for video content reported mean or median scores in the range of 2 (generally poor) to 3 (moderate quality), indicating a significant amount of missing information and high potential for misinformation across 818 videos analyzed. A total of 10 (30%) studies reported video content quality using the DISCERN or modified DISCERN instruments, with scores ranging from 25.9 (very poor) to 36.5 (fair) and 1 (low quality) to 3 (moderate quality), respectively, for 1080 videos.

Among 495 posts from the top Brazilian exercise and health Instagram accounts, Marocolo et al [33] found a high prevalence of relatively low-quality information, with an overall average quality rating of <39% and citations supporting the posted information in only 2.7% of the posts. In an analysis of 234 Pinterest pins, Dedrick et al [28] found significant missing information in 100% of the pins analyzed; 25.6% of the pins showed pictures that appeared to be touched up, and 11.5% showed before and after workout images that were not attainable based on the time frame. In 100 TikTok videos, Pfender et al [52] found that 57% of the creators recommended syncing the

XSL•FO
RenderX

menstrual cycle to specific types of exercise, while the scientific literature lacks consensus on the topic [56].

A total of 3 (9%) of the 33 studies assessed Google Search results for misinformation prevalence, each finding high prevalence. In an analysis of guidance on HIIT for pregnant women, Nagpal et al [34] found that most of the linked resources lacked key information, such as adjusting exercise intensity for prepregnancy activity level (54.5%) or trimester (57.6%), and failed to mention contraindications to exercise (87.5%). Although it included more topics along with physical activity, a study comparing Google Search results with WebMD online community answers to diabetes-related health and wellness questions found that roughly half of the answers were clinically valid or accurate (50.8% and 52.5%, respectively) [21]. Rachul et al [30] found that exercise was recommended for "immune boosting" to prevent COVID-19 infection in 30.8% of the 227 search result webpages analyzed, which is not supported by science.

A total of 21 (64%) of the 33 studies measured the potential reach of physical activity misinformation, quantified as video views, account followers, channel subscribers, video "likes," and article citations. In studies reporting video views, the range of median views per video was between 1168 and 375,039, and for those reporting mean views per video, the range was 16,471.5 to 288,597.7, with more than 43 million views. Account followers (Instagram) and channel subscribers (YouTube) were other metrics by which researchers reported the potential reach of misinformation. Marocolo et al [33] reported that the accounts analyzed in their study had a mean of 1,114,333 followers, while Zure et al [50] reported a mean of 745,476 channel subscribers in their study.

Studies measured the spread of misinformation in 2 ways. Ekkekakis et al [25] analyzed Google Search trends following a media campaign spreading misinterpreted scientific findings of a study regarding the effects of exercise on depression, finding a sharp increase of 357% in relevant searches in the month of the campaign compared to the subsequent 5 years. Several studies of TikTok were able to collect the median number of video shares, which ranged between 11 and 27 shares per video.

Discussion

Principal Findings

The purpose of this systematic review was to evaluate the state of the science related to physical activity misinformation on social media, including its reported prevalence, reach, and spread, and strategies for mitigating the issue. We found that no single physical activity topic dominated academic interest. Instead, a plurality of studies focused on physical rehabilitation and therapeutic exercise related to a wide variety of injuries or conditions. The topics related to physical activity misinformation that have been studied are as interesting as those that have received limited attention. Surprisingly, information about physical activity for weight loss was only targeted in 2 (6%) of the 33 studies. Given the public interest in weight loss, anecdotal evidence of misinformation on social media, and the history of pseudoscience and false claims, one might expect more scholarly attention to the subject. However, weight loss and similar broad topics may be challenging to study given the variety of potential misinformation.

Our review revealed that research into physical activity misinformation on social media is largely siloed, with most (24/33, 73%) studies focusing on a single social media platform. YouTube was the most frequently investigated platform, likely due to its vast repository of searchable video content and wide audience, with an estimated 81% of US adults having accessed YouTube at least once [57]. However, studies included in our review found the content to be of low-to-moderate quality, which is consistent with broader health topics on YouTube [58]. TikTok studies were also common and followed a similar methodology to those evaluating video content quality on YouTube; however, no study searched for misinformation across multiple social media platforms.

This focus on individual social media platforms fails to characterize the complex ecosystem in which misinformation spreads and may reflect methodological convenience. The narrow scope obscures critical aspects of the misinformation ecosystem, as Southwell et al [59] noted regarding the absence of misinformation research beyond social media data, potentially missing how misleading content moves between traditional media, interpersonal communication, and digital spaces. Therefore, while platform-specific analyses are useful, future research must also adopt broader approaches to better understand the cross-media dissemination of physical activity misinformation online. One approach could be to build on the method used by Ekkekakis et al [25], which involves examining the impact of a viral physical activity topic covered in mass media. Ekkekakis et al [25] found that following the publication of a particularly impactful research study, the relationship between depression and exercise was not accurately portrayed in the media. Moreover, it led to a surge in Google searches and was frequently misrepresented by other researchers who referred to the initial study. This could be extended further to evaluate the spread of this misinformation across social media platforms.

While content on a variety of social media platforms was investigated, our review identified that only 3 potentially overlapping populations have been recruited for research: college students, young women, and lactating women. This lack of diversity is a critical gap because, as Calac and Southwell [60] emphasize, misinformation exposure varies significantly across populations, yet current research fails to examine how factors such as socioeconomic status, race and ethnicity, geographic location, or disability status influence both exposure to and consequences of physical activity misinformation. This gap is especially problematic considering structural inequalities in access to safe physical activity environments where communities lacking secure outdoor spaces or well-equipped facilities may rely more heavily on online information that, if misleading, could exacerbate existing health disparities. Following the study by Southwell et al [61], future research must adopt an equity lens that examines the broader structural contexts shaping how different groups encounter and interpret health information, including those with varying levels of health

XSL•FO
RenderX

literacy and cultural attitudes toward physical activity and institutional health messaging.

While studying physical activity misinformation on social media, researchers often aimed to quantify the prevalence, reach, and spread of misinformation. We found that 27 (82%) of the 33 studies reported a metric relating to the prevalence of misinformation on a physical activity topic. Methods of measuring misinformation prevalence included evaluating the accuracy of information in popular and high-ranked videos on YouTube and TikTok, top search results on Google Search, and messages from top influencers (ie, accounts with the most followers). This suggests that there are 2 approaches to evaluating misinformation online. Taking a search-driven approach, researchers can scrutinize individual pieces of content, whereas with an account-driven approach, researchers can examine accounts that have a significant number of followers and regularly disseminate misinformation to their audience.

Quantifying misinformation reach was reported in 21 (64%) of the 33 studies. The metrics used to gauge reach included video views, account followers, channel subscribers, video "likes," and article citations. We found the median views reported were from 4100 to 375,000 per video, with total views as high as 7.7 million, which indicates a wide reach, although it is not as wide as some health topics, such as the COVID-19 vaccine [62]. Furthermore, the range of views elucidates the need for misinformation prevalence and reach to be examined together. For example, Güloğlu et al [38] showed that while misleading videos were prevalent (51.2%) and of a significantly lower quality (GQS=2 vs. GQS=4), they had a lower reach compared with videos classified as useful—25.7% and 74.3% of total views, respectively. However, in other cases, the opposite can easily be true, as studies noted that content popularity had no correlation or negative correlation with content quality [32,39,43,49].

While knowing the reach of misinformation is important for understanding the dynamics of misinformation, measuring its spread is equally critical, yet this metric was not often reported in the included studies. Of the 33 studies, our review identified 1 (3%) study that quantified the spread of physical activity misinformation through Google Search trends and several (n=5, 15%) others through the number of video shares on TikTok. More work needs to be done to fully understand how physical activity misinformation propagates within and across various platforms.

Recommendations for Combating Misinformation

Our review of the current literature suggests that the challenge of physical activity misinformation on social media is unlikely to be resolved without proactive intervention. On the basis of the evidence, a multipronged approach is necessary to mitigate its impact. First, the quality and framing of physical activity messaging are critical. Content should be framed positively, highlighting short-term social and mental health benefits, and should be tailored to the intended audience using formative research and established psychological principles [63]. Content seeking to debunk misinformation should target specific misconceptions [64] and information seekers with a personal connection to the issue [13]. This approach of creating high-quality, targeted content should be adopted by institutions to directly compete with the deluge of poor-quality information online. With that goal, Haslam et al [65] have described 10 factors to enhance the accessibility of credible health content on platforms such as YouTube, which is essential for reaching a wide audience.

In addition to these social media content strategies, health professionals can play a vital preventive role during patient consultations by ensuring patients' questions are fully addressed, as unresolved queries often lead individuals to seek information from less reliable online sources [31]. Finally, the spread of misinformation can also be disrupted at a key source: the communication of health research to the public. Academic journals writing press releases for studies should be mindful that news organizations often lack the incentive or expertise to highlight flaws in research methods and are not inclined to revisit a nuanced topic when a similar study is later published [66]. By implementing strategies that focus on creating high-quality content, improving professional practice, and ensuring accurate science communication, the impact of health misinformation can be reduced.

Areas for Future Research

While this review describes the current state of research on physical activity misinformation on social media, it also reveals gaps that future research must address. First, there is a lack of research extending beyond content analysis to measure the impact of physical activity misinformation on real-world behavior. Future research should use experimental designs to test how exposure to specific types of physical activity misinformation influences intentions, decisions, and subsequent behaviors. Second, the current research landscape is predominantly cross-sectional "snapshots" of misinformation on single platforms, which fails to capture how misleading narratives evolve and spread. Therefore, we recommend longitudinal studies to investigate the misinformation over time. Third, manual analysis methods (eg, GQS and DISCERN) common among the studies we reviewed are not scalable for comprehensive, real-time detection. A promising area for future work is the development and validation of artificial intelligence–driven tools to detect physical activity misinformation. These models could be engineered to identify unsubstantiated claims (eg, "immune boosting" exercise) and pseudoscientific language specific to fitness, health, and wellness. Large language models have shown effectiveness in this area [67,68], but caution should be taken as large language models have also been shown to propagate health misinformation [69,70]. Addressing these areas will move the field beyond describing the problem of physical activity misinformation on social media toward mitigating its impact on public health.

Limitations

Our systematic review of physical activity misinformation on social media has several limitations that readers and future researchers in the field should consider. In many (10/33, 30%) of the articles that met our inclusion criteria, the words misinformation, fake news, or disinformation were not used. Instead, these articles discussed the accuracy, quality, or validity

XSL•FO
RenderX

of content. While we used a wide array of search terms, there may have been similar keywords we missed, which leaves the possibility that our search excluded relevant articles. In our search, there was also potential bias introduced by the selected databases and self-reported data in some studies, along with publication bias, which means studies finding minimal misinformation may be underrepresented in the published literature. We omitted any articles not published in English. As social media, physical activity, and misinformation are not limited to the English-speaking world, this may have excluded relevant articles. In our review, we found high variability in study topics, designs, and purposes and limited coverage of topics, platforms, and populations, making it difficult to conduct a traditional quality assessment or draw firm conclusions. Often, studies did not share the same outcome measures or report the same metrics related to misinformation, limiting synthesis and the ability to apply a misinformation classification scheme. Finally, we found a lack of longitudinal studies tracking misinformation over time, which limits our ability to draw conclusions about its impact.

Conclusions

The objective of this systematic review was to identify original research studies on physical activity misinformation on social media to better understand its prevalence, reach, and spread. In addition, we aimed to highlight ways to mitigate its impact and areas for further investigation. Our review revealed that physical activity misinformation is a multifaceted issue that presents in various forms across a range of physical activity topics, social media platforms and types, study populations, and study designs. Therefore, studying this issue requires a multidimensional approach that uses a diversity of research methods. Our hope is that future researchers recognize this complexity and explore new avenues for investigating the dissemination and propagation of misinformation, especially across social media platforms.

Authors' Contributions

DDT conceptualized the study, developed the methodology, analyzed and interpreted the data, and drafted the original manuscript. LX assisted with the early conceptualization of the study, development of the methodology, and reviewed drafts of the manuscript. BY, OA, JA, and IC assisted with data synthesis and analysis and reviewed drafts of the manuscript. XL and YL assisted with the methodology and editing of the drafts of the manuscript. SPM, the senior author, conceptualized the study, developed the methodology, provided resources, supervised the work, validated the results, and reviewed and edited the manuscript.

Abstract

Background: Sexual and reproductive health and rights (SRHR) are foundational to both individual autonomy and global well-being. Misinformation in this domain poses serious risks by undermining evidence-based decision-making, weakening systems of accountability, and perpetuating social injustices.

Objective: This scoping review aimed to map and synthesize evidence on the forms, spread, and impacts of misinformation related to SRHR in digital spaces, with a particular focus on implications for the protection and promotion of human rights.

Methods: We conducted a scoping review of scientific papers and gray literature. It was guided by the JBI (Joanna Briggs Institute) population, exposure, and outcomes framework. The extracted information was documented following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist. Thematic analysis was carried out and mapped against human rights standards: (1) equality and nondiscrimination; (2) Availability, Accessibility, Acceptability, and Quality; (3) informed decision-making; (4) privacy and confidentiality; (5) participation and inclusion; and (6) accountability.

Results: Of the 254 eligible studies and documents, 133 focused on the information ecosystem, 37 on the individual, 32 on service delivery and health system, 31 on law and policy, and 21 on community levels. SRHR misinformation impacts individuals' informed SRHR decisions by shaping their beliefs, attitudes, and health-seeking behaviors. It reinforces harmful and discriminatory social norms at community levels and the exclusion of marginalized voices. SRHR misinformation impacts health systems by shaping provider knowledge and practice, disrupting service delivery, and creating barriers to equitable care. It may function as a legal and policy tool to erode SRHR protections. The design of online platforms, digital marketing strategies, and content moderation policies enables misinformation to spread widely while restricting credible SRHR content.

XSL•FO
RenderX

Conclusions: SRHR misinformation in digital spaces is a systemic issue that undermines human rights across multiple levels, highlighting the urgent need for integrated, rights-based approaches to research, policy, and intervention.

Introduction

Access to accurate, evidence-based information is integral to realizing sexual and reproductive health and rights (SRHR). The ability to make informed decisions across the full spectrum of sexual and reproductive health (SRH)—from the prevention of health-harmful practices to contraception, fertility, pregnancy, and lifelong sexual health and well-being—is fundamental to health, dignity, population resilience, and enables people to thrive into the future [1]. Misinformation [2] in this domain can pose significant risks by undermining evidence-based decision-making, eroding accountability, and perpetuating injustices. Although public health programs have thorough experience and expertise in providing credible, accurate health information to clinicians, patients, and the public, these long-standing approaches have been strained in the past two decades by rapidly changing information ecosystems [3-5]. How people seek and consume health information has changed with the digitization of information exchange and the ubiquity of consumer-centered and device-mediated information consumption. Digital access to health information is particularly critical for adolescents, who rely on online sources for education and support [6].

Misinformation is defined as false, inaccurate, or misleading information shared without intent to deceive [2]. It differs from disinformation, which involves the intentional spread of false or misleading content to profit from, deceive, or manipulate individuals or communities [2]. While these two concepts are distinct in terms of intent, they often operate in overlapping and reinforcing ways within digital environments and leverage the same features of the information ecosystem and vulnerabilities of online users [7]. In practice, the outcomes of both misinformation and disinformation, such as confusion, mistrust, stigmatization, and harm, can be similarly damaging, especially in the context of SRHR. SRHR disinformation is included in this review as a particularly harmful form of misinformation, with the potential to deliberately erode human rights protections and restrict access to evidence-based care.

Both mis- and disinformation spread rapidly in digital spaces, which are online environments where people interact, share content, and consume information. These include social media platforms (eg, Facebook [Meta], X [formerly known as Twitter; X Corp], and Instagram [Instagram from Meta]), websites, forums (eg, Reddit [Reddit, Inc], comment sections under news or blog posts), blogs, messaging apps (eg, WhatsApp [Meta] and Telegram [Telegram Messenger Inc]), and other digital platforms (eg, Alexa [Amazon.com, Inc] and Google Maps [Google Inc]). However, this digital ecosystem is far broader than traditional social media: people also encounter and negotiate SRHR narratives in the digital information environment within gaming communities, livestreaming platforms, pornography sites, dating apps, and short-form video environments such as TikTok or YouTube Shorts (Google LLC). These varied spaces are not only sites of information transmission, but also of identity formation, social bonding, entertainment, and emotional expression, all of which shape how users interpret and act on health-related messages. For many individuals, particularly youth and marginalized communities, these platforms have become primary sources of SRHR knowledge, community, and meaning-making. Yet, they also enable the amplification of inaccurate or deceptive content, often without adequate moderation or accountability. This can distort individuals' perceptions, influence health-related decisions and behaviors, reinforce harmful norms and stigma, and erode trust in public health guidance and institutions [8,9].

The broader field of misinformation research is rapidly evolving. It is moving beyond static definitions of false content and intentions to spread it to embrace a more dynamic, contextualized understanding of how information and narratives flow through digital spaces and impact social norms and behaviors [3], and learning from specific health contexts such as vaccine demand promotion, science communication, cancer treatment and prevention, and pandemic preparedness and outbreak response [4,10-14]. Scholars and public health leaders increasingly recognize that interventions focused solely on individual knowledge, fact-checking, or improved digital marketing are insufficient in addressing the structural and systemic nature of the problem [3,9,14-17]. Misinformation does not merely reflect gaps in public understanding, but intersects with identity, emotion, prior experience, and the relational dynamics that shape trust and meaning-making [3,8,16,18].

Public health responses to misinformation have often focused on correcting individual behaviors rather than addressing systemic failures in information governance [14,15,17,19]. Public health efforts that continue to emphasize scale through adaptable digital communication and engagement risk replicating limited impact if they do not adapt to the lived realities of how people seek, share, and interpret health information and experience relationships online [15,16,18]. This shift in understanding has catalyzed calls for more equity-centered, interdisciplinary, and reflexive approaches that engage with information ecosystems holistically, recognize user agency and curation, and address power imbalances in how knowledge is produced and accessed [2,3,14-18,20].

The information environment refers to the dynamic set of ecosystems [21] of all the communication channels, platforms, actors, narratives, and interactions that influence how individuals

XSL•FO
RenderX

receive, process, and use information. Often, public health functions do not have strong policies or funded programs designed to address information environment challenges or mitigate their harms to health, and many new efforts were stood down after the pandemic due to a lack of resources and integration into routine programming [5,17,19,22].

In the context of SRHR, the information environment includes not only digital platforms but also how it intersects with traditional media, community networks, health systems, legal frameworks, socially built identities, and social norms that shape the flow and interpretation of SRHR information. Additionally, the World Health Organization (WHO) has identified artificial intelligence (AI)–generated misinformation as a growing threat to SRHR [23], and the United Nations (UN) has recognized the role of digital platforms in shaping the SRHR information landscape and has raised concerns about governance and accountability [24]. Companies that operate these platforms have a responsibility to respect human rights; yet, content moderation policies and advertising models often allow misinformation to proliferate [25,26].

This scoping review maps existing literature on how misinformation related to SRHRs circulates in digital spaces, with the aim of identifying dominant themes, gaps in the literature, and implications for human rights protection (reducing harm) and promotion (enabling autonomy). It introduces human rights standards to an analysis in information science and misinformation studies, and is not an interpretation of existing legal frameworks that are used in international law in relation to SRH and health information. At the same time, it adds a socioecological lens to the analysis of SRH misinformation literature, which enables a more comprehensive discussion of influences and impacts at each of the socioecological levels, as well as interactions between them.

This paper is the first in a series of publications that will emerge from the data collected during the review. This paper examines SRHR misinformation through the levels of the socioecological model and aims to inform future research priorities and guide the development of rights-based, evidence-informed interventions in an increasingly complex and rapidly evolving digital information landscape. While this paper focuses on the human rights impacts of SRHR misinformation, future papers from this review will map, describe, and discuss the drivers and amplifiers of SRHR misinformation, and interventions and recommendations.

Methods

Study Team

The core study team consisted of five members with expertise in health communication, misinformation studies, community engagement, information science and analytics, medicine, sociology, SRH, gender, and human rights. A project advisory group was convened and consulted in defining the scope, distributing a web survey to networks and experts, reviewing findings, and reporting results. Consultations with SRHR practitioners and policy makers, human rights experts, and digital health and health communication specialists were conducted to identify additional sources of gray literature, validate findings, and provide contextual insights on addressing SRHR misinformation.

Study Design

We used the JBI (Joanna Briggs Institute) manual for evidence synthesis for the overall process of review and analysis [27]. We followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist [28] (Multimedia Appendix 1).

The objective was to organize and summarize available literature and inform future research on the incidence, types, and influence of SRHR misinformation in digital spaces and its effects at the individual, community, health system, law and policy, and information ecosystem levels, from a human rights perspective.

Identifying Research Questions

The following questions guided the scoping review: (1) What are the common types of SRHR misinformation and narratives in the digital information environment? (2) How is SRHR misinformation amplified in the digital information environment, and why or for what reasons? (3) What kind of effect does SRHR misinformation and narratives in the digital information environment have on individuals, communities, service delivery, laws, and policy?

To effectively answer these questions, we adopted the population, exposure, and outcome framework developed by the JBI [29]. The population, exposure, and outcome criteria were as follows: P (population)—research and gray literature focused on SRHR misinformation in digital information environment affecting individuals, communities, health workers, or policy makers; E (exposure)—misinformation related to SRHR topics such as contraception, fertility, abortion, maternal health, sexual health, and bodily autonomy; and O (outcomes)—impacts on decision-making, health-seeking behavior, health service delivery, community norms, laws, and policies.

The corresponding inclusion and exclusion criteria are summarized in the SRHR misinformation Table 1.

XSL•FO
RenderX

Table 1. Summary of inclusion and exclusion criteria for papers in this scoping review focused on misinformation in digital spaces related to sexual and reproductive health and rights.

	Included	Excluded
Paper type	Original research papers, policy analyses, policy reports, and commentaries published in peer-reviewed research journals and gray literature	Preprints, duplicates, theses, or book chapters
Methodology	Can include any methodology or type of research (qualitative, quantitative, and mixed methods)	N/A[a]
Geography	Any country or region	N/A
Language	English	Not in English
Publication date range	January 1, 2019, and November 23, 2024	Outside of January 1, 2019, and November 23, 2024
Full text available?	Yes	No
Related to topics in sexual and reproductive health and rights (eg, contraception, fertility, abortion, maternal health, and bodily autonomy)	Yes	No
Related to misinformation in digital spaces (eg, includes social media, apps, and the internet)	Yes	No
Related to health information–related outcomes? (eg, decision-making, health-seeking behavior, health service delivery, community norms, laws, and policies)	Yes	No

[a]N/A: not applicable.

Search Strategy

We considered qualitative, quantitative, and mixed-methods studies, commentaries, policy analyses, and gray literature in English. We searched PubMed, Scopus, Web of Science, JStor, and HeinOnline databases with a search strategy presented in Multimedia Appendix 2. In addition to more traditionally used databases in information science (PubMed, Scopus, and Web of Science), additional searches were also performed in JStor and HeinOnline. JStor, as Web of Science, covers humanities and social sciences, but it is more expansive, which was deemed useful to locate more papers for this study. HeinOnline covers legal and law-related materials and was included to search for current discussions of SRHR misinformation in digital spaces, as impacts on law were part of the research question.

Search terms were tested and developed iteratively from narrow to the final broader definitions to intentionally capture the diversity of studies that might otherwise not be included because they used diverse keywords and terms in relation to SRH and misinformation. We included studies and documents published and made available in the databases between January 1, 2019, and November 23, 2024.

Information environment dynamics, related regulatory, platform, and consumer protection policies, user trends, and narratives change quickly and are often first described in gray literature before scientific papers. As we wanted to capture the current discussions and evidence, and the SRHR misinformation impacts are often described in gray literature such as relevant government, UN, and nongovernmental organization reports and newspapers, we also searched Google and Google Scholar. In addition, policy and evidence reports were also suggested by key informants via a web survey on the WHO website that was open for 6 weeks, between November 25, 2024, and January 5, 2025, and advertised through WHO SRHR networks and social media.

Document Screening and Inclusion

Two investigators searched and screened the documents by titles and abstracts, and then reviewed the full texts of potential documents to include. The screening by titles and abstracts focused on excluding and marking as irrelevant the studies that did not relate to SRHR misinformation and digital spaces, were in a language other than English, or that were books, book chapters, or theses. The subsequent full-text review focused on applying all exclusion and inclusion criteria to the remaining studies. Conflicts were resolved through consensus between the two investigators. Records were managed in the Covidence systematic review software [30]. We excluded any documents not in English, reviews and meta-analyses, and those that did not focus on misinformation in the digital information environment or misinformation in SRHR.

Data Extraction

A data extraction form was developed to extract data from included studies. The form included fields to capture information about the study or document (authors, title, journal or publisher, and country or region) and document or study characteristics (study type, digital setting, and human rights standards). It also captured misinformation characteristics (topics and types), underlying drivers and attributions, digital channel, impacts of misinformation, affected populations (by social group, identity, or vulnerability), legal and policy implications, interventions and solutions, and additional notes.

XSL•FO
RenderX

Summarizing and Reporting the Results

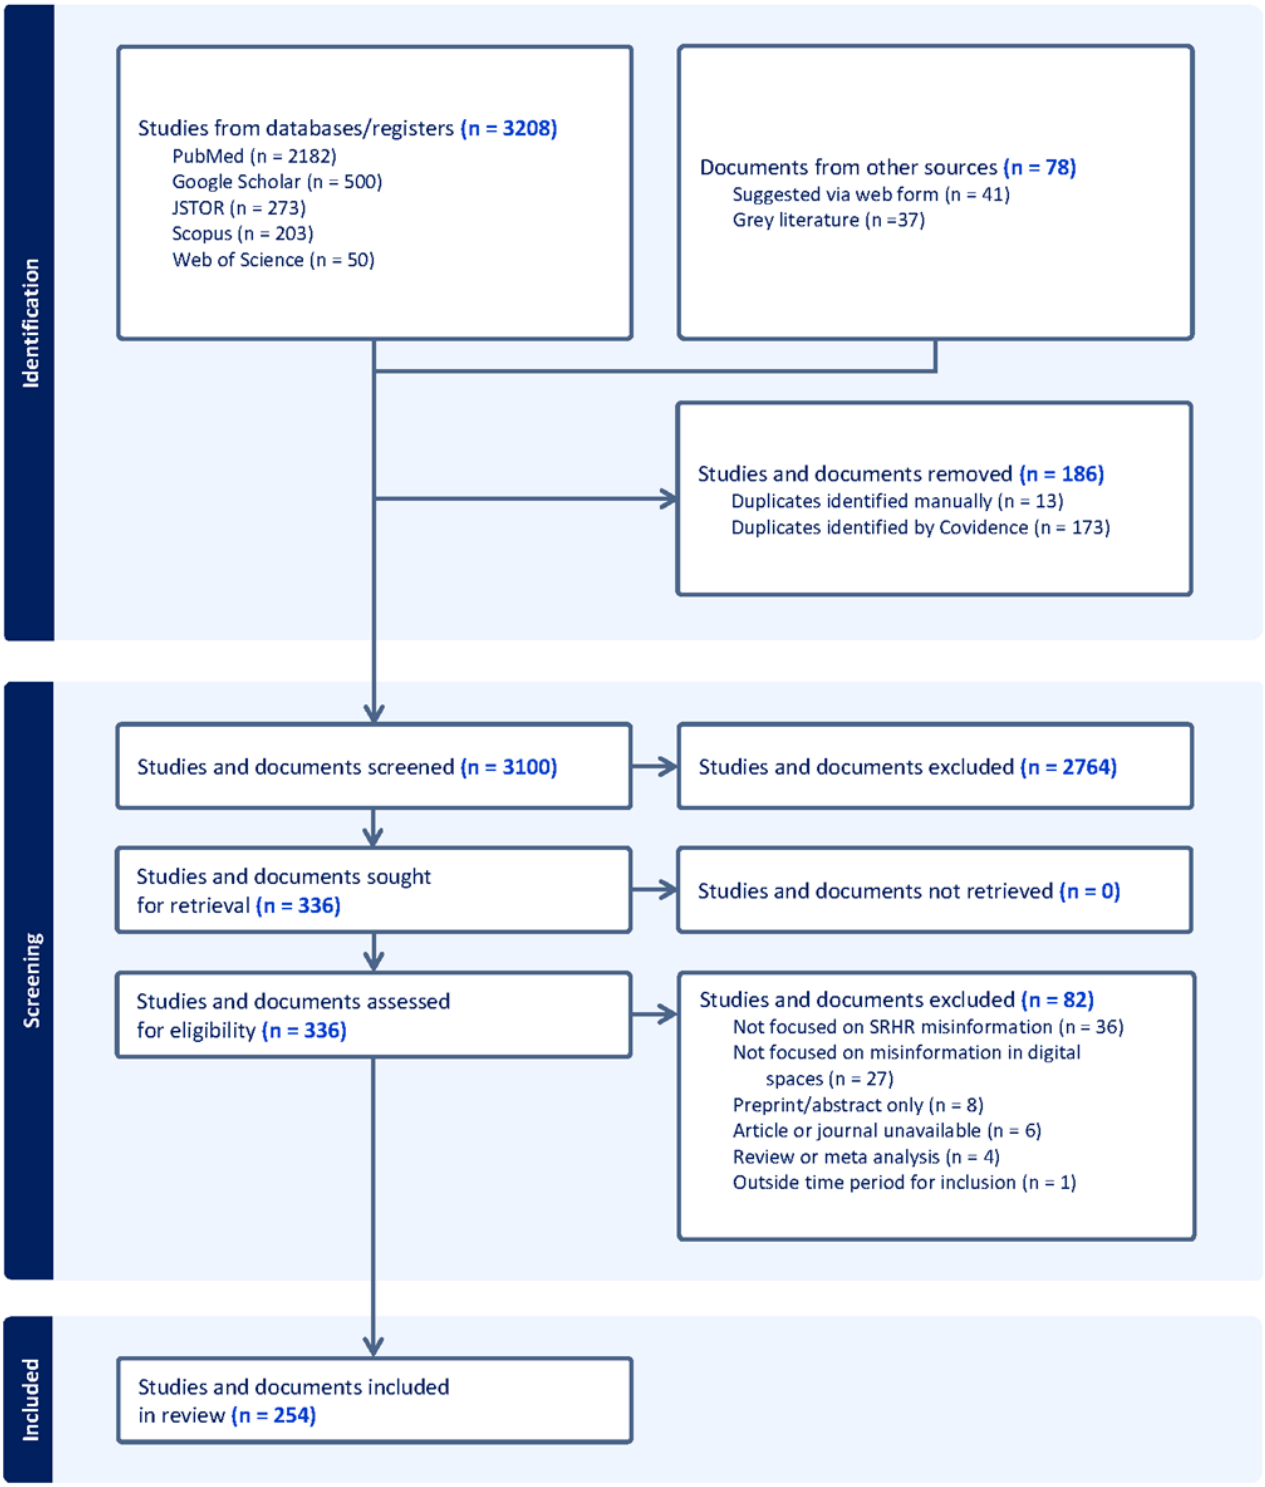
We conducted a thematic content analysis using narrative descriptions of the extracted data, and mapped it against categories of human rights standards, namely (1) equality and nondiscrimination, (2) Availability, Accessibility, Acceptability, and Quality (AAAQ), (3) informed decision-making, (4) privacy and confidentiality, (5) participation and inclusion, and (6) accountability. The sources for the human rights standards applied include international and regional human rights treaties, the general comments and recommendations issued by the UN human rights treaty-monitoring bodies, international and regional court decisions, and international and regional consensus documents. The application of these to the area of SRH was made on the basis of WHO guidelines, taking "Ensuring Human Rights in Contraceptive Information and Services: WHO Guidance and Recommendations" (2014) [31] as a key reference and point of departure. We organized the results by levels of the socioecological model: individual, community, service delivery and health system, law and policy, and information ecosystem. The work was performed by two analysts and reviewed by two other reviewers.

Patient and Public Involvement

This study did not involve patients or the general public. Their input was not sought in the scoping review design, interpretation of results, or drafting or editing this document.

Ethical Considerations

This study was a scoping review of publicly available literature and documents, and ethical approval was not required.



Results

Overview

We retrieved 3208 studies from databases and an additional 78 documents from gray literature sources. After removing duplicates, 3100 records remained for screening of titles and abstracts, of which 336 were retrieved for full-text screening. A total of 82 records were excluded for the following reasons: not focused on SRHR misinformation (n=36), not focused on misinformation in digital spaces (n=27), was a preprint or only had an abstract available (n=8), unavailable to retrieve (n=6), review or meta-analysis (n=4), outside of time period for inclusion (n=1). In total, 254 studies and documents were included in the final review. The study selection process is outlined in the PRISMA-ScR flow diagram in Figure 1.

XSL•FO
RenderX

Figure 1. PRISMA-ScR flow diagram. PRISMA-ScR: Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews; SRHR: sexual and reproductive health and rights.

Description of Included Studies and Documents

Characteristics of Studies and Documents

Of the 254 studies and documents (Multimedia Appendix 3 [23,24,32-278]), 77% (n=195) were from scientific journals and 23% (n=59) from gray literature. Detailed figures describing the studies and documents are listed in Multimedia Appendix 4. All analysis was carried out on the full dataset of studies and documents, and referred to as “studies” for the rest of this paper.

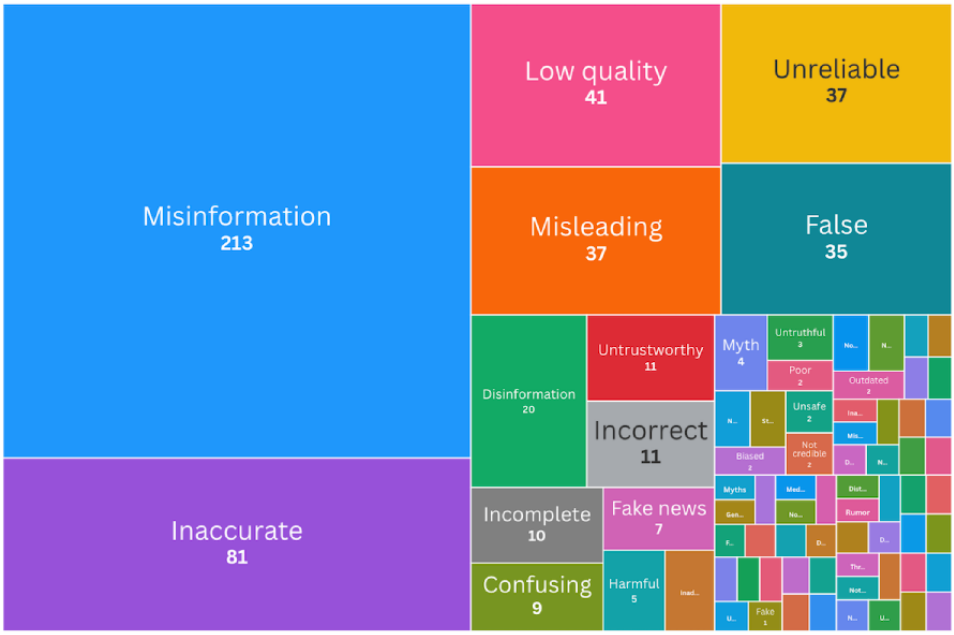
Not all studies referred to specific geographies; 43% (n=40) had a global focus, 39% (n=37) focused solely on the US context, and 18% (n=16) focused on other country contexts.

In total, 45 countries or regions were covered in the studies. The 5 countries included in most studies were the United States (n=80), Canada (n=12), Australia (n=9), Brazil (n=7), and the United Kingdom (n=5), followed by studies of the digital environment spanning the European region (n=5). Only 10% (n=26) of studies and documents specified the language of the

XSL•FO
RenderX

misinformation that was covered; 12 analyzed English content, followed by Spanish (n=4), French (n=4), Portuguese (n=2), Dutch (n=1), Russian (n=1), Malay (n=1), and Ukrainian (n=1).

Among the included studies, 49% (n=125) are qualitative and focused on the description of digital SRH misinformation in specific populations, specific settings, and on specific SRH topics. Other types of studies were quantitative studies (n=27), news or magazine articles (n=25), commentaries (n=24), mixed-methods studies (n=16), reports (n=15), policy analyses (n=8), legal analyses (n=8), advocacy materials (n=2), webinars or podcasts (n=2), and toolkits or tools (n=2).



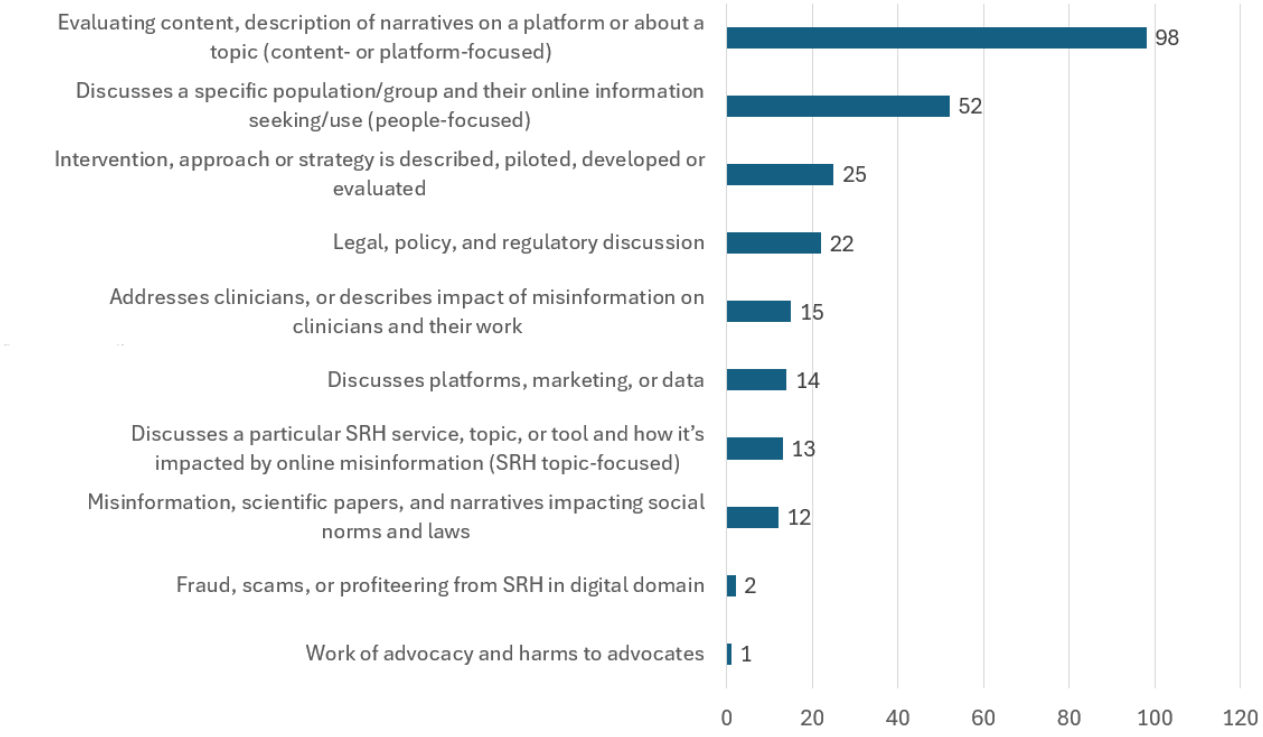
More than half (n=149, 57%) of the 254 studies described specific challenges or characteristics of online SRHR misinformation but did not make any recommendations or list strategies for action. A total of 86% (128/149) of those were from scientific journals.

Characteristics of SRHR Misinformation

For each study, terms that were used to describe misinformation were logged. Across all studies, 75 different terms were used to refer to misinformation, and often multiple terms within the same study. A treemap was generated with the Fourish [279] web tool, where the number of studies (of total 254) that used each term is represented with a proportionally-sized box (Figure 2). Underlying data for the treemap is in Multimedia Appendix 4.

The SRH topics that were covered by the studies were very diverse and are summarized in Multimedia Appendix 4, by topics referred to by authors or communities described in the study. More than 25% (n=72) of all studies discussed SRHR in broad terms, while those focusing on specific topics included maternal and perinatal health (n=36), safe abortion and postabortion care (n=30), fertility, infertility and assisted reproduction (n=20), vaccines (n=19), contraception and family planning (n=17), men's SRH (n=16), adolescent SRH (n=13), LGBTQ+ (Lesbian, Gay, Bisexual, Transgender, Queer, and more) SRH (n=12), gender-based violence and sexual violence (n=6), sexually transmitted infections, including HIV (n=4), menstrual health and hygiene (n=3), cervical cancer and human papillomavirus (HPV) prevention (n=2), and SRHR in public health emergencies (n=1).

Figure 2. A treemap of terms used to refer to SRH misinformation in studies included in the scoping review. The number next to each term represents the count of the studies that used it when referring to misinformation. SRH: sexual and reproductive health.



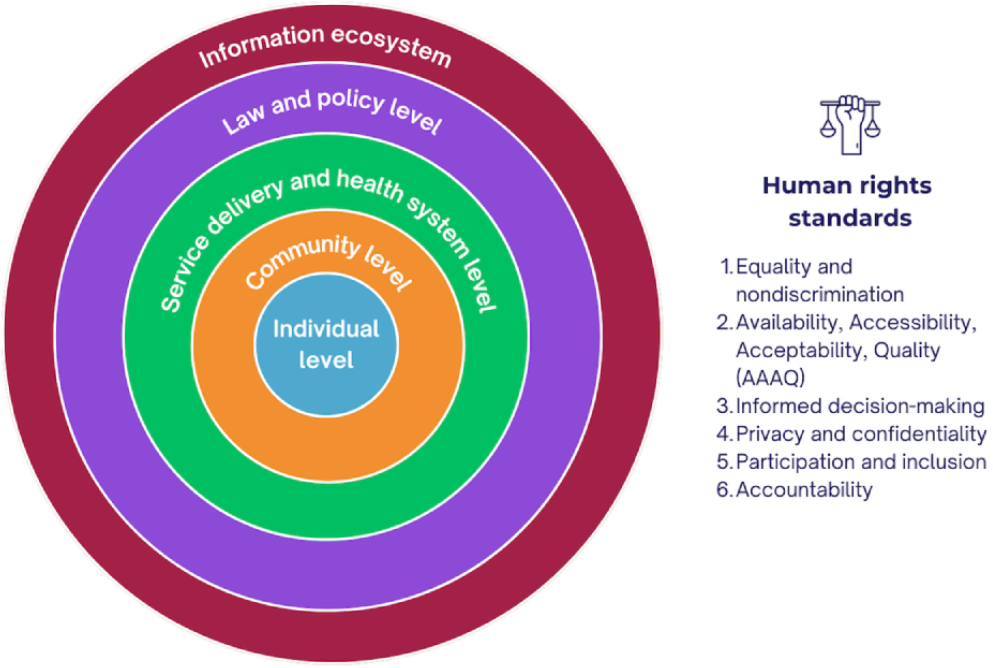
Digital Contexts and Settings

Regarding digital information environment or settings covered, the most commonly discussed were digital platforms in general (n=151, 59%) and social media (n=98, 35%), while far fewer discussed search engines (n=8, 3%), advertising and marketing (n=8, 3%), and online forums (n=6, 2%). If specifically mentioned, 23 different platforms were discussed across all studies and documents, most commonly X (formerly known as Twitter; n=32), Facebook (n=28), YouTube (Google LLC; n=26), and TikTok (n=26).

An exploratory categorization of the studies and documents by topic discussed in relation to misinformation was developed as a preliminary overview, as existing taxonomies are not integrative and omit aspects that would need further coding in this dataset. This exploratory categorization showed that the most common types of study were about content- or platform-focused issues, how specific groups use digital spaces for SRH, descriptions of interventions and strategies, and legal and policy discussions (Figure 3). The exploratory categorization will be discussed in more detail in future papers.

XSL•FO
RenderX

Figure 3. Exploratory categorization of types of misinformation discussion across included studies and documents. SRH: sexual and reproductive health.



Human Rights Impact of SRHR Misinformation by Level of the Socioecological Model

Overview

The results reported below used an analysis framework (Figure 4) that mapped the impacts of SRHR misinformation on human rights standards across the levels of the socioecological model. Organized by the socioecological model, 52% (n=133) studies and documents focused on the information ecosystem, followed by 15% (n=37) at the individual level, 13% (n=32) at the service delivery and health system level, 12% (n=31) at the law and policy level, and 8% (n=21) at the community level. The following sections present a mapping of the existing literature describing SRHR misinformation impacts on human rights, and reference illustrative examples from the included studies. A detailed mapping of included studies and documents by levels of the socioecological model is presented in Multimedia Appendix 5 [23,24,32-127,129-133,135-170,172-175,177-180,182-193,195,197-213,215-218,220-236,239-249,251,252,254-278,280,281].

RenderX

Figure 4. An analytical framework used in the analysis of misinformation impacts on human rights protection (reducing harms) and promotion (enabling autonomy) in the digital information environment. AAAQ: Availability, Accessibility, Acceptability, and Quality.

Individual Level: Misinformation Disempowers Individual SRHR Decision-Making and Autonomy

Overview

The data collected through this review shows how SRHR misinformation directly undermines individuals' autonomy by distorting health beliefs, shaping attitudes, and disrupting health-seeking behaviors. These effects are mediated by cognitive biases, social influences, and disparities in digital access and literacy. The human rights standard most consistently impacted by SRHR misinformation at the individual level is the right to informed decision-making. Impacts on access to acceptable and quality health services, and equality and nondiscrimination, particularly among youth, people of color, LGBTQ+ individuals, and people in conservative settings, were also documented. While the impact on accountabilities for human rights protection is less directly visible at the individual level, it may arise when platforms and systems fail to protect users from targeted misinformation.

Misleading Information Online Limits Individuals' Ability to Make Autonomous, Informed SRHR Decisions, Exacerbated by Increasing Reliance on Digital Sources for Health Information

Misinformation online undermines individuals' ability to make autonomous, informed SRHR decisions, especially as reliance on digital sources grows. People seeking information about contraception, fertility, abortion, or sexual health frequently encounter misleading content that influences beliefs and behaviors [32-34]. This can cause confusion and anxiety, particularly during public health crises [35]. For example, while 61% of Dutch women use pregnancy and childbirth apps, these were seen as less trustworthy than professional advice [36]. In Brazil, many new mothers use the internet to verify or replace provider guidance [37], and in Italy, 76% of women with endometriosis reported encountering online misinformation about their condition [38,39]. Similarly, 55% of men surveyed at an outpatient urology clinic in Canada reported searching online for information about men's SRH and expressed concern about the pervasiveness of misinformation in the digital information environment [40]. Exposure to misinformation can also reinforce existing beliefs; one study found that inaccurate beliefs about fetal pain were linked with antiabortion views, shaping attitudes toward access and policy [41].

Misinformation Exacerbates Digital Inequities and Perpetuates Distrust, Fear, Stigma, Discrimination, and False Narratives

Studies show how digital misinformation amplifies stigma and discrimination, particularly for groups experiencing social exclusion, deterring individuals from seeking care. LGBTQ+ individuals, people of color, and those from lower-income backgrounds face higher exposure to misinformation, reinforcing existing disparities in SRHR knowledge and access [42-44]. One study described how misinformation campaigns on social media about Tenofovir-based pre-exposure prophylaxis have contributed to mistrust and hesitancy among Black, Latinx, and multiracial individuals, many of whom began to question the safety of pre-exposure prophylaxis after viewing targeted legal advertisements [44]. Similarly, social media discourse has fueled "hormonophobia" and skepticism toward hormonal contraception, often promoting unsubstantiated claims and emphasizing side effects over benefits—especially among women of color, exacerbating distrust in health care providers, contributing to vaccine hesitancy, skepticism toward contraceptives, and fear-based narratives about SRH [45].

Lack of Digital Access, Insufficient Health, Media, and Digital Literacy, and Lack of Protections Against Online

XSL•FO
RenderX

Abuse and Fraud Make Individuals Vulnerable to Misinformation

Limited digital, information, media, and health literacy and health care access worsen misinformation exposure, leaving individuals vulnerable to scams, misinformation-driven health decisions, and fraudulent SRHR products. Women seeking fertility information online often encounter misinformation, particularly in non-Western digital spaces, leading to confusion and poor health choices [46,47]. Scammers exploit individuals seeking reproductive health solutions, as seen in Nigeria, where fraudulent "miracle fertility treatments" exploit vulnerable women with deceptive promises and financial scams [280].

Community Level: Misinformation Reinforces Stigma, Silencing, and Resistance to SRHR

Overview

The review shows that misinformation at the community level reinforces harmful social norms, perpetuates stigma, and contributes to the exclusion of marginalized voices. Human rights standards related to equality and nondiscrimination are routinely impacted, particularly when gender stereotypes, religious ideologies, or cultural beliefs are used to delegitimize SRHR. Access to quality health services and information and informed decision-making are compromised by peer-driven misinformation, while participation and inclusion are weakened when misinformation silences dissent or misrepresents marginalized populations. Furthermore, impacts on human rights accountability remain an implicit concern where misinformation is amplified by community leaders, influencers, or unregulated local media.

Reinforcement of Harmful Gender and Social Norms

The mapped evidence shows how misinformation perpetuates stigma against SRHR services and marginalized identities, discouraging individuals from seeking care or engaging in public discourse. Worldwide, women and girls report concerns about navigating misleading SRHR information online, in particular in spaces where misogynistic and anti-LGBTQ+ rhetoric thrives [48]. LGBTQ+ individuals face heightened misinformation exposure, particularly regarding fertility, contraception, and HIV prevention, which influences community norms and limits health care access [42-44,49]. For instance, a study in Aotearoa New Zealand found that WSW are significantly less likely to engage in cervical screening due to a legacy of misinformation about their cancer risk, reinforced by heteronormative public health messaging and provider assumptions that exclude their sexual histories [49].

Spread of Misinformation Within Communities Leads to Discriminatory Behaviors or Resistance to Evidence-Based SRHR Practices

Community-based misinformation shapes SRHR choices and can lead to harmful health behaviors. Antivaccine narratives in online parenting communities have influenced vaccine refusal, shaping norms that undermine public health efforts [50]. In South Africa and Southeast Asia, youth report misinformation, stigma, and intergenerational barriers as major obstacles to accessing SRHR services [34,51]. Online misinformation has promoted ineffective fertility-tracking methods [52,53] and also contributed to declining use of modern contraception among young people [52,53]. In Wales, for instance, uptake of the combined contraceptive pill dropped significantly between 2019 and 2023, with clinicians linking the trend to pervasive "horror stories" on TikTok and Instagram that exaggerate side effects and create fear among young women seeking care [52].

SRHR Advocates Face Online Violence, Exclusion, and Disinformation Campaigns

SRHR misinformation fuels harassment, exclusion, and violence against individuals and organizations advocating for sexual and reproductive rights. Reproductive justice organizations face content suppression, misinformation-driven backlash, and barriers in digital advocacy [54-56]. Antirights groups actively weaponize misinformation to delegitimize SRHR movements, as seen in Kenya and Ethiopia, where foreign-funded campaigns influenced policy decisions and public discourse [57,58]. Gendered disinformation and digital violence disproportionately target women and LGBTQ+ advocates, discouraging their participation in public life [59,60]. Deepfake revenge pornography and manipulated digital content have been used to spread false narratives and intimidate SRHR advocates [60]. Gendered disinformation legitimizes violence against women and LGBTQ+ individuals while distorting discussions on gender and reproductive rights [59].

Service Delivery and Health System Level: Misinformation Degrades Trust, Service Delivery, and Health Worker Roles in SRHR

Overview

Misinformation at the service delivery and health system level undermines the quality and equity of SRHR care. It influences provider knowledge, patient expectations, and institutional practices, compromising the AAAQ of services and information. Informed decision-making is eroded when patients rely on misinformation or when providers themselves disseminate false claims. Equality and nondiscrimination are implicated when misinformation leads to substandard care for marginalized groups. Impacts on privacy and confidentiality are underdiscussed in the literature we reviewed, but are relevant, especially when digital health tools compromise user data.

Health Workers May Disseminate or Be Influenced by Misinformation, Contributing to Biased or Low-Quality Care

Health care providers are increasingly confronted with responding to misinformation from patients, impacting clinical decision-making and patient trust. In Australia and the United States, doctors report an increase in patients not choosing contraception when offered, requesting unnecessary procedures, or expressing concerns about reproductive health due to misinformation spread on social media [52,53,61]. Providers themselves are not immune to misinformation, as seen in deceptive marketing targeting men's health clinics, fertility treatments, and aesthetic gynecological procedures [62-65]. For example, an investigation into direct-to-consumer men's health clinics in the United States found widespread promotion of low testosterone treatments and erectile dysfunction therapies, often unsupported by robust evidence, and noted that clinics rarely

XSL•FO
RenderX

disclosed provider credentials, contributing to potential misinformation and compromised patient safety [65]. Similarly, several studies have shown that fertility clinics routinely market unproven IVF "add-ons," such as embryo glue or endometrial scratching, often presenting them as effective despite limited or no supporting evidence [62,64]. Additionally, some health care professionals share misinformation online, blurring professional boundaries and undermining public trust in medical expertise [66].

Misinformation Can Prevent or Disrupt the Delivery of SRHR Goods and Services

SRHR misinformation creates barriers to the provision of evidence-based services, particularly for contraception, abortion, and vaccines. Misinformation about (HPV) vaccines, abortion safety, and fertility treatments affects patient decision-making and reduces uptake of essential SRH services [33,67,68]. In Wales and the United States, declining contraceptive use has been linked to misinformation on TikTok and Instagram promoting unreliable fertility-tracking methods [52,53]. In a hospital in Canada, internal policies have restricted access to abortion-related websites, limiting providers' ability to offer full referral pathways for patients [69].

Barriers to Equitable and Accessible Service Provision Arise From Misinformation About Health Systems or Workers

Misinformation fosters distrust in health care providers and discourages care-seeking behaviors, particularly among marginalized populations. Pregnant women, individuals with abnormal cervical screening results, and those seeking abortion services report turning to online sources due to fear of provider judgment or legal uncertainty—only to encounter further misinformation that heightens anxiety and confusion [70-72]. Antichoice narratives and misinformation about fetal tissue have shaped patient expectations and fueled clinic harassment, making it harder for providers to deliver compassionate, evidence-based care [73]. Additionally, health workers face online harassment and disinformation campaigns, further discouraging their active engagement in SRHR service provision and public education [74-77].

Law and Policy Level: Misinformation Is a Legal and Policy Tool for Eroding SRHR Protections

Overview

At the law and policy level, the review shows that misinformation can act as a mechanism for institutionalizing discrimination and rolling back SRHR protections. It shapes legal frameworks, drives policy enforcement decisions, and creates ambiguity that undermines informed decision-making and access to acceptable and quality health services. Most findings implicate governments' human rights accountabilities, revealing weak regulation, misuse of science, and institutional complicity in the spread of disinformation. Equality and nondiscrimination and privacy, and confidentiality are routinely compromised through discriminatory laws and digital surveillance. While human rights standards related to participation and inclusion are less emphasized, misinformation suppresses engagement and discussion across differences and stifles civil society advocacy.

Legal Manipulation and Policy Distortion Through Misinformation

Misinformation influences the creation or perpetuation of discriminatory laws. False narratives shape restrictive SRHR policies by misrepresenting scientific evidence and swaying public opinion. In the United States, misinformation about late-term abortions and abortion pills has influenced state-level restrictions, despite FDA (Food and Drug Administration) assurances of their safety [78]. Similarly, Ghana's anti-LGBTQ+ bill has been fueled by foreign right-wing disinformation campaigns that mischaracterize reproductive rights and LGBTQ+ advocacy as threats to society [58].

Policy decisions based on misinformation also harm equitable SRHR access. Misinformation has justified restrictive SRHR policies that limit access to essential health care. In Nigeria, false claims about how SRHR issues were integrated in the Samoa Agreement led to a national political crisis despite official debunking efforts [79]. Similarly, US laws restricting emergency contraception access have been shaped by misinformation falsely equating the emergency contraception with abortion [80].

Misinformation may also prevent effective implementation of laws and policies designed to promote and protect SRHR through health systems. Legal uncertainty and misinformation discourage providers from delivering SRHR services, even where laws permit them. Unclear abortion laws in the United States have created confusion, leading to provider reluctance to offer legally available care [78]. In Canada, a Catholic hospital restricted provider access to abortion-related websites, limiting their ability to offer comprehensive referrals [69].

In the United States, the Project 2025 playbook outlines strategies to embed misinformation into federal governance by altering agency mandates and rewording policies to stigmatize and delegitimize SRH [81]. These tactics aim to institutionalize SRHR misinformation, making it harder for the public to access accurate and credible information about abortion and related services [81].

Surveillance, Privacy, and Targeting of SRHR Users and Advocates

Private digital user data from tools, platforms, and devices has been used for surveillance, the spread of misinformation, and harassment related to SRH. Digital surveillance tools have been used against individuals seeking SRHR services. Antichoice activists and law enforcement agencies in the United States have used private digital user data, geofencing, and web histories to track abortion seekers and misdirect them to crisis pregnancy centers [82,83]. LGBTQ+ users have also faced privacy risks, as seen when Grindr (Grindr LLC) was labeled a national security threat due to concerns over foreign intelligence misuse of user data, without broader protections for LGBTQ+ digital privacy [84].

Barriers to Advocacy and Accountability

Efforts to counter SRHR misinformation are frequently obstructed by platform restrictions and targeted attacks on reproductive rights advocates. Reproductive justice organizations struggle to promote accurate information due to

XSL•FO
RenderX

advertising restrictions on social media platforms, limiting outreach efforts [55]. Human rights defenders advocating for SRHR face harassment, smear campaigns, and violence, further discouraging public discourse on reproductive rights [85].

Misinformation may distort human rights accountability systems, affecting justice outcomes for those claiming their sexual and reproductive rights. Misinformation undermines evidence-based policymaking and accountability mechanisms. In the United States, flawed research linking abortion to mental health risks—despite being widely discredited—has been cited in legal cases to justify abortion restrictions [86]. Gendered misinformation also weakens legal protections against online violence, as existing laws often fail to address digital threats and harassment effectively [59].

Information Ecosystem Level: Information Ecosystem Design Systemically Undermines SRHR Rights and Equity

Overview

This review reveals that the information ecosystem, comprising social media, search engines, digital ads, algorithms, mobile apps, AI agents, other online spaces, and platform governance, is a key enabler of systemic SRHR misinformation. Platform design choices and business models allow misinformation to flourish while silencing accurate, rights-based content. This results in impacts across all six categories of human rights standards: algorithmic bias reinforces discrimination, censorship of accurate SRHR content limits AAAQ, exposure to misleading content undermines informed decision-making, tracking and surveillance violate privacy, content moderation suppresses participation, and regulatory inaction weakens accountability.

Platform Architecture and Digital Business Models Enable Harm From SRHR Misinformation

Misinformation distorts public discourse, crowds out accurate information, and undermines trust in credible, accurate SRHR information and sources. SRHR misinformation spreads rapidly in high-engagement digital spaces, reinforcing stigma, confusion, and distrust in public health sources. During the 2022 mpox outbreak, social media misinformation fueled stigma against sexual minority men and gender-diverse individuals, reinforcing discrimination [87].

SRH misinformation has been monetized in an unregulated digital information ecosystem, undermining consumers' ability to make informed choices. Platforms, influencers, and wellness brands profit from misleading SRHR narratives, making it harder for individuals to access evidence-based guidance. YouTube, TikTok, and Instagram influencers promote unregulated fertility apps, alternative contraceptive methods, and nonevidence-based treatments for polycystic ovary syndrome and erectile dysfunction [88-92]. Google and Meta profit from deceptive advertising, directing users searching for abortion services to crisis pregnancy centers that provide misleading information [93].

Vague and inconsistently enforced content moderation policies enable misinformation while restricting SRHR advocacy. Social media platforms fail to regulate misinformation effectively while disproportionately censoring SRHR content. Meta restricts advertising by abortion providers while allowing antichoice misinformation to spread unchecked [93]. Google search results for abortion medication often lead to misleading crisis pregnancy centers [94]. Additionally, retail platforms such as Amazon (Amazon.com, Inc) have been reported to restrict or delist vaginal health products—such as therapeutic devices for pelvic pain—labeling them "potentially embarrassing," thereby limiting access to essential women's health products and reinforcing stigma around SRH care [282].

Inequities in SRHR Content Access and Algorithmic Asymmetries and Discrimination

Inequalities in digital access, the design of internet platforms, and digital marketing tools lead to uneven exposure to accurate SRHR information. Algorithmic bias and content moderation disparities create unequal access to accurate SRHR information. Platforms inconsistently apply moderation policies, disproportionately censoring sexual health content while allowing misinformation to flourish, particularly in low-income countries [95-97]. In Egypt and Western Asia, SRHR advocates face content suppression, including blocked ads and limited reach [56].

The quality of SRHR health information online is low, with misinformation incidence rates ranging from 14% to 97% across topics and platforms [98-119]. Studies show 41% of Facebook articles about HPV vaccination contained misinformation [115], 28% of YouTube videos about erectile dysfunction included misleading content [102], and 73% of TikTok videos about gynecological cancers were of poor quality [99].

Global Flow and Amplification Mechanisms of Misinformation

Digital misinformation on SRHR easily transcends national boundaries, affecting global health policies and legislation. Far-right groups in Europe have replicated US misinformation campaigns, targeting LGBTQ+ rights and reproductive health access [120]. In Kenya, a far-right group manipulated X (formerly known as Twitter) discussions to derail support for reproductive health bills [121,122].

Triggers of misinformation surges include public events, sensationalized news, and humor. Misinformation spikes during public health emergencies and policy changes. The reversal of Roe versus Wade triggered an abortion-related infodemic, where evolving laws, social media misinformation, and inadequate content moderation fueled confusion [94,123]. News coverage of contraceptive lawsuits has exaggerated risks, shaping global perceptions and fueling misinformation [124]. Additionally, a rising antirights movement in Ethiopia, aligned with the US Christian Right, is working to dismantle the right to safe and legal abortion, propagating SRH misinformation online, all the while gaining influence in political spaces [57].

Drivers of misinformation amplification in the digital information environment include scams, memes, clickbait, and marketing. SRHR misinformation spreads through viral content, influencer marketing, and deceptive digital campaigns. Scammers posing as fertility experts in Nigeria have exploited vulnerable women with false "miracle treatments" [280].

XSL•FO
RenderX

Another emerging form of online harm involves "Munchausen by internet," where individuals fabricate perinatal illnesses and crises in real time—such as neonatal death—using fake online personas [125]. These cases can emotionally manipulate and mislead health care providers, wasting their time and creating distress when the deception is uncovered [125]. In addition, memes on TikTok are used to evade content moderation while spreading misinformation about contraception and sexual health [126].

Lack of regulation or accountability for digital health misinformation undermines public health efforts. SRHR misinformation remains largely unregulated, enabling bad actors to shape digital discourse. WHO has identified AI-generated misinformation as a growing threat to SRHR, as AI tools produce misleading reproductive health content with little oversight [23]. Efforts to counter misinformation are often obstructed by digital platform policies, limiting reproductive justice advocacy [55].

Discussion

Principal Findings

This scoping review maps and describes existing literature on misinformation in SRHRs, suggesting that it is rarely limited to isolated myths, individual misunderstandings, or politicized topics. Instead, the evidence reviewed points to SRHR misinformation as being entangled with the broader social, political, and digital systems through which health information is searched for, interpreted, shared, and acted upon. Traditional responses to health misinformation have often focused on correcting false beliefs through education, counter-messaging, or fact-checking, which are based on communication frameworks and exclude systems thinking and information environment, approaches, and analysis through human rights standards. The literature reviewed highlights concerns that such approaches may be insufficient, particularly given the disproportionate impacts on underserved communities. Several studies suggest that SRHR misinformation can operate within wider structures of inequality, stigma, and power, and in some cases, may be deliberately used to undermine reproductive autonomy, challenge evidence-based care, or reinforce discriminatory ideologies.

This scoping review focused on the five years since 2019 specifically because the digital information environment, architectures, algorithms, platform moderation policies, as well as socioeconomic dynamics have been changing rapidly, also in relation to how we understand misinformation and the wider impacts of the information environment on health behaviors. Capturing the recent experience of users seeking health information, support, and care in digital spaces more closely reflects the digital realities of today. During this time, users online have experienced a shift to reduced moderation on many large platforms [26,283] and related polarization of conversations in digital spaces [284,285], the impacts of the pandemic on straining health systems health promotion programs and their capacity to address the information environment [20], as well as rapidly evolving ways users seek information, support and companionship through synthetic companions and AI-powered tools and interfaces. The themes coming out of this review show that this changing sociotechnical landscape is both concentrating harms in groups that seek SRHR-related support and care online, and at the same time, the features of the information environment are used by communities to exercise autonomy in relation to how they access, discuss, and act on health information.

These insights are aligned with the growing shift in the broader health misinformation research and practice field, where scholars have called for moving beyond individual-level interventions to engage with the systemic, emotional, and relational dynamics that shape how people encounter and respond to information. The results of the mapping underscore that SRHR misinformation is not an exception but a critical and often overlooked example of these wider dynamics.

This paper is the first of three planned publications based on this scoping review's dataset and focuses on cross-mapping information science and misinformation research with human rights principles. The overall purpose of this work is to bring the research and advocacy community across different fields together to improve human rights protection and promotion in the context of SRHR misinformation in digital spaces. Future papers will detail the attributes of SRHR misinformation and harm, and interventions reported in the included studies, while the third will be the result of a consultation with human rights scholars and advocates on improving concepts and monitoring frameworks of the harmful impact misinformation has on SRHR protection and promotion.

What Makes SRHR Misinformation Distinct

What makes SRHR misinformation distinct from misinformation in other health areas (such as vaccine-preventable diseases, cancer, or emergency preparedness and response) is its intrinsically gendered and politicized nature. SRHR is deeply connected to individual autonomy, social identity, and cultural norms. Misinformation in this space is not only shaped by stigma and taboo, but it often also reinforces them. It is commonly weaponized to control reproductive choices, restrict access to care, and limit public discourse on gender and sexuality. Unlike many other health domains, SRHR misinformation often targets and impacts people differently based on their gender identity, sexual orientation, reproductive status, or age, reinforcing longstanding power imbalances.

Increasingly in most contexts, the search for SRHR information begins and ends online. Many individuals, particularly those in marginalized or stigmatized communities, seek answers to sensitive questions via the likes of search engines, mobile apps, social media, AI agents and tools, and private messaging platforms. Due to its intimate, gendered, and relational nature, SRHR misinformation does not just distort facts. It also shapes how people understand their rights, identities, and relationships. These characteristics make SRHR topics particularly vulnerable to disinformation, where individuals, influencers, or organizations deliberately spread misleading narratives or promote unproven products and services for financial gain or political influence.

XSL•FO
RenderX

Addressing the harm from SRHR misinformation, therefore, goes beyond correcting content or narratives and requires confronting and transforming the systemic drivers, commercial incentives, and sociopolitical norms that produce and legitimize harmful information about SRHR.

Terminological and Conceptual Inconsistencies

The analysis in Figure 2 reflects what kinds of contextualization and value judgments are placed on the concept of misinformation in the studies included in this review. Importantly, this review reveals a wide diversity in the terminology used to describe SRHR misinformation. While the most common terms used are "misinformation" and "inaccurate," the rest of the terms used all point to an attribute or impact of information itself, not merely its accuracy. Terms such as "misleading," "inappropriate," "unreliable," "gendered disinformation," "myths," "incomplete," and "harmful narratives" were used across the studies. This suggests that authors from different disciplines (eg, public health, law, or media studies) and professional groups (eg, clinicians, health educators, policy analysts, or advocates) differently interpret and frame the qualities of information, such as its accuracy, relevance, intent, and social impact. This might stem from the drivers and harms perceived as most relevant to SRHR. These conceptual differences likely shape how misinformation is approached in the literature and by advocates and may present challenges for synthesizing evidence, developing effective interventions, and creating shared standards across health topics and research disciplines. Future research must grapple with this definitional pluralism and embrace cross-disciplinary approaches that can accommodate and bridge these varied perspectives. One approach to acknowledge this diversity is to move from discussing "misinformation" to studying "information environment," as many of the drivers and impacts, including harms, described in this paper are related to social, cognitive, and other drivers of how information is interpreted and meaning is made, rather than the accuracy of a piece of information alone.

These terminological inconsistencies also reflect a deeper fragmentation in the research, beyond language, regarding how the problem of SRHR misinformation is conceptualized and situated within broader systems. This scoping review shows that while there is growing recognition that SRHR misinformation is a public health issue, the literature remains fragmented. Most of the studies identified in this review focus on describing or measuring misinformation in specific domains or platforms (such as abortion or contraception, YouTube or X [formerly known as Twitter]), with fewer addressing the broader political, cultural, and systemic conditions that shape the production, circulation, and impact of misinformation in SRHR. This pattern mirrors wider critiques in the health misinformation research field, which caution against overly narrow, content-focused approaches that overlook the complexity of digital ecologies and information environments. As recent scholarship has argued, health misinformation is not simply a matter of individual belief or factual inaccuracy, but a relational and evolving process shaped by identity, emotion, trust, and social context [2,3,14]. Our findings underscore the need for SRHR misinformation research to engage more fully with these broader frameworks to inform more effective, equity-oriented responses.

Human Rights Framework and Structural Harms

A key contribution of this review is the application of a human rights framework to map the harms of SRHR misinformation across the socioecological model. We found that misinformation impacts multiple human rights standards, including informed decision-making, equality and nondiscrimination, availability and quality of information, services and goods, privacy, participation, and accountability. These violations occur at different levels, undermining individual autonomy, fueling stigma within communities, disrupting evidence-based service delivery, enabling discriminatory laws and population surveillance, and fostering unregulated information ecosystems that prioritize virality over veracity. This lens clarifies how SRHR misinformation is not merely a matter of faulty information, but rather that it is a matter of human rights, social justice, and systemic inequity.

Notably, this review highlights a gap in current SRHR and human rights literature and practice—while the right to SRH has long emphasized access to accurate information, it has yet to fully grapple with how information ecosystems—including ecosystem architecture, algorithmic governance, and commercial content moderation and marketing tools [24,26]—function as structural determinants of health. Digital environments now shape not only what information is available, but whose voices are amplified, whose experiences are silenced, and whose health is protected or compromised [2,14]. The failure to regulate or even acknowledge these dynamics constitutes a failure of accountability [24,26].

Implications for Research, Policy, and Practice

Understanding misinformation as ecosystemic has major implications for public health, policy, and advocacy. Health systems can no longer treat misinformation solely as a public education issue and must engage with how SRHR information is designed, curated, and circulated across digital infrastructures. This requires a shift from short-term, message-based communication and reactive debunking to proactive governance that supports digital literacy, designs inclusive information pathways, and builds social cohesion and institutional trust. SRHR advocates that communities, especially marginalized communities, must be protected from online harassment and supported to participate meaningfully in digital public spheres.

Policy makers must reaffirm access to accurate, evidence-based health information as a public good and a fundamental human right, rather than a consumer product vulnerable to manipulation. Regulatory frameworks should ensure transparency in platform algorithms, protection of privacy, and equitable access to information. Meanwhile, digital platforms must be held accountable for the role they play in facilitating and profiting from SRHR misinformation. Monitoring and addressing these harms will require collaborative efforts across sectors, including health, education, technology, and law, and must center the voices of those most affected by SRHR misinformation and information injustice.

XSL•FO
RenderX

This therefore points to several research priorities in this space. First, there is a need to move beyond cataloguing misinformation content to studying how SRHR misinformation functions within broader digital ecosystems—not only how it spreads, why it resonates with particular communities, and how trust in different sources is constructed, but also what are the "dark patterns" that propagate vulnerabilities of SRHR, the commercial determinants of SRHR misinformation, and the evolving relationships with information online that discard its tactfulness for relatability. Second, future work should explore how individuals and groups resist, reinterpret, or correct misinformation, particularly in marginalized communities, and what forms of digital literacy and social support strengthen resilience. Third, more research is needed into the interactions between misinformation, digital platform design, and regulatory policies, including how algorithmic amplification works, how the use of private user data has been monetized, and content moderation affect health-related rights. Finally, interdisciplinary inquiry should investigate how to embed human rights frameworks into technology governance, including the development of accountability indicators that assess whether information environments support or hinder the right to SRHR. These research directions are essential to inform rights-based, equity-driven strategies to counter SRHR misinformation at scale.

Limitations

This scoping review has several limitations. First, our inclusion criteria restricted the search to English-language sources, which may have excluded relevant studies published in other languages. Second, by focusing exclusively on the digital information environment, we did not capture insights from offline spaces or additional media channels where SRHR misinformation might also circulate and impact communities. Third, we included only studies and documents explicitly addressing misinformation, and this approach may have overlooked research that does not focus on misinformation but on other challenges within the information ecosystem that share drivers, amplifiers, and attributes with misinformation, such as questions, concerns, information voids, hate speech, or disinformation (for promoting ideas or products for profit or influence).

Conclusions

The consequences of SRHR misinformation in the digital information environment include restricted bodily autonomy, compromised reproductive justice, and distorted policy environments. SRHR misinformation includes a wide spectrum of topics, platforms, and various effects and harms that infringe on human rights principles and standards. This scoping review described the multitudinous social, technological, and regulatory drivers that shape discourse about health online and the many ways individuals' SRH and human rights are affected by it online and offline. No single level of the socioecological model is sufficient to describe the scope and effects of SRHR misinformation in the digital information environment, and solutions are also unlikely to be found at a single level.

Although this scoping review cataloged some of the effects and harms of SRHR misinformation, fuller accounting is needed to understand the cumulative effects and harms of SRHR misinformation in individuals, communities, health systems, and societies. Inspiration can be drawn from more established fields of health misinformation and behavioral science research in vaccines, cancer, and pandemic preparedness, where misinformation is a common risk to health care decisions and behaviors, and has been long studied, and impacts have been well-catalogued.

The internet will only become more ingrained in the day-to-day lives of people and their families and communities, and so, the SRHR field must evolve with this now indispensable source of information, connection, and care to help everyone realize their right to SRHR health care everywhere, including online.

Acknowledgments

The authors would like to thank everyone who submitted gray literature and provided feedback during the online data collection period. TDP used OpenAI's ChatGPT to review the prefinal drafts for structure, readability, English style, and grammar, and edited them to improve them accordingly. The transcript of the ChatGPT conversation used in the preparation of this paper is attached as Multimedia Appendix 6. TDP used Grammarly (Grammarly, Inc) for spellcheck and sentence editing. This paper reflects the views of the named authors, and not necessarily the views of UNDP (United Nations Development Programme)/UNFPA (United Nations Population Fund)/UNICEF (United Nations Children's Fund)/WHO (World Health Organization)/World Bank Special Programme of Research, Development and Research Training in Human Reproduction (HRP) or World Health Organization.

Funding

This work received funding from the UNDP-UNFPA-UNICEF-WHO-World Bank Special Programme of Research, Development and Research Training in Human Reproduction (HRP), a cosponsored program executed by the WHO. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of this paper.

Authors' Contributions

ÅN, TDP, EW, DS, CW, SB, BG, AL, GM, and TT conceptualized this study. ÅN and TDP supervised this study. ÅN was responsible for project administration. TDP, EW, DS, CW, and ÅN developed the methodology. TDP, EW, DS, CW, and ÅN conducted the investigation and validation of results and wrote the original draft of the paper. TDP prepared the visualizations. TDP, EW, DS, CW, ÅN, SB, BG, AL, GM, and TT critically reviewed and edited this paper. All authors approved the final version of this paper.

Conflicts of Interest

TDP is the associate editor of JMIR Infodemiology and did not participate in the journal's handling or decisions regarding this paper.

Abstract

Background: Opioid overdose is a global public health emergency, with the United States experiencing high rates of morbidity and mortality due to prescription and illicit opioid use. Traditional public health monitoring systems often fail to provide real-time insights, limiting their capacity for early detection and intervention. Social media platforms, especially Reddit, offer a promising alternative for timely toxicovigilance due to the abundance of user-generated, real-time content.

Objective: This study aimed to explore the use of Reddit as a real-time, high-volume source for toxicovigilance and develop an automated system that can classify and analyze opioid-related social media posts to detect behavioral patterns and monitor the evolution of public discourse on opioid use.

Methods: To investigate evolving social media discourse around opioid use, we collected a large-scale dataset from Reddit spanning 6 years, from January 1, 2018, to December 30, 2023. Using a comprehensive opioid lexicon—including formal drug names, street slang, common misspellings, and abbreviations—we filtered relevant posts for further analysis. A subset of these data was manually annotated according to well-defined annotation guidelines into 4 categories: self-misuse, external misuse, information, and unrelated, with distributions of 37.21%, 27.25%, 27.57%, and 7.97%, respectively. To automate the classification of opioid-related chatter, we developed a robust natural language processing pipeline leveraging classical machine learning algorithms, deep learning models, and transformer-based architecture, and fine-tuned a state-of-the-art large language model (LLM; OpenAI GPT-3.5 Turbo). In the final stage, the trained LLM was deployed on an unlabeled dataset comprising 74,975 additional Reddit chatter posts. This enabled a detailed temporal analysis of opioid-related discussions, aligned with 6 years of opioid-related death records from the Centers for Disease Control and Prevention (CDC). For this study, self-misuse and external misuse were merged into a misuse category for direct comparison with the CDC's mortality data, examining whether trends in social media discourse on opioid misuse reflect patterns in real-world mortality statistics.

Results: The fine-tuned GPT-3.5 Turbo model achieved the highest classification accuracy of 0.93, outperforming the baseline (random forest 0.85) by representing a performance improvement of 9.14% over the machine learning model. The temporal analysis of the unlabeled data revealed evolving trends in opioid-related discussions, indicating shifts in user behavior and overdose-related chatter over time. To quantify this relationship, we calculated the Pearson correlation coefficient between misuse-related posts and CDC death records (r=0.854). This correlation was statistically significant (P<.001), indicating a strong positive relationship between web-based discussions and CDC mortality data.

Conclusions: This study demonstrates the potential of integrating advanced natural language processing techniques and LLMs with social media data to support real-time public health surveillance. Reddit provides a valuable platform for identifying emerging trends in opioid use and overdose risk. The proposed system offers a proactive tool for researchers, clinicians, and policymakers to better understand and respond to the opioid crisis.

Introduction

Background

An opioid overdose occurs when a toxic amount of opioids—such as prescription painkillers like oxycodone, hydrocodone, and morphine or illicit drugs such as heroin and fentanyl—slows vital functions such as breathing and heart rate, potentially leading to death. Opioids can be classified into natural opioids (eg, morphine and codeine), semisynthetic opioids (eg, oxycodone, hydrocodone, and heroin), and synthetic opioids (eg, fentanyl, methadone, and tramadol), each differing in potency, pharmacokinetics, and overdose risk. The United States is currently facing a severe epidemic, with opioids being the leading cause of drug addiction and overdose [1]. In 2017, it was estimated that more than 72,000 deaths occurred due to drug overdoses, and opioids were involved in more than 47,000 of these cases, accounting for approximately 68% of all overdose deaths [2]. This translates to an average of more than 130 opioid-related deaths per day, with approximately 46 deaths daily linked specifically to prescription opioids [3]. The opioid epidemic in the United States has evolved in distinct waves: the first wave was driven by prescription opioids, the second wave was driven by increased heroin use, and the third wave was driven by synthetic opioids, such as fentanyl. Recent reports suggest a potential fourth wave involving polysubstance overdoses, particularly synthetic opioids combined with stimulants [4]. Data from the Centers for Disease Control and Prevention (CDC) highlight that some states, including West Virginia, Ohio, and Pennsylvania, experienced particularly high death rates, exceeding 40 per 100,000 people in 2017, alongside statistically significant year-over-year increases [5].

Variations in opioid overdose mortality across the US states are influenced by multiple factors, including differences in prescription policies and the public's awareness and education regarding opioid risks and benefits [5]. Despite recognizing these geographic disparities, efforts to monitor the opioid crisis remain severely lacking [6,7]. Existing surveillance systems are hindered by considerable delays, making it difficult to evaluate the immediate impact of new policies and interventions [8-10]. Kolodny and Frieden [11] have highlighted many of the limitations of current monitoring efforts and proposed 10 federal-level actions to combat the opioid epidemic, with enhanced surveillance and monitoring identified as a critical priority.

The US Food and Drug Administration recognizes social media as a valuable source of real-world evidence for drug monitoring [12-14]. In addition to this, social media have increasingly become an important tool for public health surveillance [15-19], offering insights into various health-related trends, including drug abuse and misuse [20-25]. As the use of social media such as X, Reddit, Facebook, and YouTube continues to grow at an unprecedented rate, the volume of health-related discussions shared online has expanded significantly. When analyzed carefully, this chatter offers unique insights into patterns of substance use, which are often difficult to capture through traditional methods. Studies have shown that posts mentioning opioids and other addictive substances often carry clear signs of misuse, with many individuals openly sharing experiences they might hesitate to disclose in clinical settings [26-32]. This behavior highlights a major challenge in addressing the opioid crisis: despite struggling with addiction, many individuals avoid seeking professional help due to barriers such as time constraints, financial hardship, stigma, and a general lack of awareness about available treatment options.

While early studies based on manual analysis highlighted the potential of social media for drug abuse research, fully realizing this potential requires automated, data-driven approaches. However, social media data present a number of challenges for natural language processing (NLP) and machine learning, including frequent misspellings, the use of slang and informal language, data imbalance, and significant noise. To overcome these hurdles, researchers have developed a range of automated techniques, such as rule-based systems, supervised classifiers, and unsupervised learning methods. Notably, most studies exploring opioid-related discussions have relied on unsupervised approaches, often without fully filtering out irrelevant content or rigorously evaluating their methods. Despite these challenges, this body of work has firmly demonstrated the value of social media for toxicovigilance and paved the way for building real-time, end-to-end surveillance systems based on social media data.

NLP plays an essential role in classifying and exploring opioid overdose trends using social media discourse. Social media platforms contain large amounts of first-hand user-generated textual, video, and image data, including posts about drug use, overdose experiences, and discussions on opioid addiction. NLP helps in mining helpful information from these data by identifying keywords and patterns related to opioid use. It also classifies rising overdose cases, tracks geographical trends, and explores public reactions to opioid crises. Techniques such as sentiment analysis, named entity recognition [33], and text classification enable better monitoring. Moreover, NLP can help health care professionals and policymakers by providing real-time insights, helping in early intervention and prevention efforts.

In this study, we designed and evaluated an NLP and a large language model (LLM) to create an automated and robust social media pipeline for toxicovigilance. The proposed system uses supervised LLM to automatically classify opioid-related discussions into 4 predefined categories, such as personal experience, external experience, information, and not related, and integrates temporal data from Reddit to monitor the opioid crisis in specific time frames. For this purpose, we used 6 years of publicly available social media posts from Reddit, dated between January 1, 2018, and December 30, 2023. A total of 5045 posts were manually annotated through a rigorous process,

XSL•FO
RenderX

following a set of annotation guidelines specifically developed for this dataset in collaboration with experts in addiction medicine. Each post was categorized into 1 of 4 clearly defined labels. The annotation was performed by 2 domain annotation experts and the corresponding author [34,35]. Final labels were determined through majority voting to ensure consistency and minimize individual bias. Among these, 1877 posts (37.21%) were classified as related to self-misuse, 1375 (27.25%) were classified as related to external misuse, 1391 (27.57%) were classified as informational, and 402 (7.97%) were classified as unrelated. The opioid-related posts were identified using a comprehensive list of prescription and illicit opioid names, including street names.

After preparing the dataset, we applied and evaluated a diverse range of models, including traditional machine learning models, such as logistic regression (LR), random forest (RF), support vector machine (SVM), and Extreme Gradient Boosting (XGB), using term frequency–inverse document frequency (TF-IDF) features. For deep learning, we implemented convolutional neural networks (CNNs) and bidirectional long short-term memory (BiLSTM) networks using pretrained word embeddings, such as FastText and GloVe. In addition, we experimented with 4 transformer-based models—XLM-RoBERTa (XLM-R), DistilBERT, multilingual bidirectional encoder representations from transformers (mBERT), and ClinicalBERT—using contextual embeddings. To further enhance performance, we incorporated a state-of-the-art LLM, GPT-3.5 Turbo, leveraging its contextual understanding for classification. On the basis of our evaluation, the fine-tuned LLM-based model achieved the best performance with an accuracy of 0.93—representing a 9.41% improvement over the best classical machine learning model, RF (0.85). These results highlight the effectiveness of fine-tuning LLMs for capturing nuanced patterns in opioid-related social media discourse.

We analyzed 6 years of social media chatter on the opioid crisis using an LLM, examining 74,975 unlabeled posts from 2018 to 2023. This temporal analysis revealed patterns in online discussions about misuse that often paralleled trends in CDC-reported opioid deaths. A Pearson correlation analysis confirmed a strong positive association between misuse-related posts and CDC death records (r=0.854, P<.001), highlighting that social media activity closely reflects real-world mortality trends.

Prior Work

Webster et al [36] analyzed Canadian news media coverage of opioids, highlighting a shift from medical pain treatment to criminalization. They showed how media narratives polarize individuals as either victims or criminals while downplaying the pharmaceutical industry's role. This framing leads to stigmatization and punitive responses rather than effective solutions.

Dekeseredy et al [37] analyzed 5068 tweets about medications for opioid use disorder to understand public discourse. They found themes of suspicion, conspiracy theories, frustration over treatment access, and stigmatizing language. This stigma on social media may discourage people from seeking treatment.

Russell et al [38] analyzed 2836 Facebook comments on news posts about the opioid epidemic in Ohio. They found 2 main perspectives: most (61.1%) supported addiction as a disease requiring treatment, whereas a significant minority (38.9%) blamed individuals and dismissed the crisis. Media framing did not influence how addiction was discussed. These findings highlight both support and stigma in public discourse.

Hedberg [39] analyzed how male and female opioid users are represented in Ohio newspapers, revealing gendered biases. Male users are portrayed more leniently, often with humor, whereas female users are stigmatized as "erratic" and penalized for failing as caregivers. This language reinforces societal perceptions and may shape policy responses.

Johnston [40] analyzed racial representation in Canadian news media coverage of opioid deaths, highlighting differences in how White and Indigenous users are portrayed. They argued that White users are often seen as innocent victims, whereas Indigenous users face stigma. Drawing on media studies by Hall and others, the author examined how race influences drug-related narratives. They also discussed harm-reduction policies and Indigenous leaders' calls for culturally based treatment approaches.

Jaafar [41] analyzed language patterns in social media discussions of drug addiction, focusing on common metaphors and frames. Using corpus linguistics, it finds that addiction is largely associated with negative and life-threatening risks. The research highlights how language shapes public attitudes and informs policy and health communication strategies.

Henson [42] analyzed public perceptions of fentanyl through YouTube videos and comments, revealing both informed discussions and illicit drug marketing. Using semantic network analysis, it identifies public awareness of evidence-based treatments and the sources of the crisis. The findings highlight the need for health policy interventions to protect online discourse and combat illegal drug sales.

Sarkar et al [43] created a labeled dataset of 9006 geolocated tweets, categorized into 4 classes: abuse related, informational, unrelated, and non-English, and trained multiple machine learning classifiers, with their best ensemble model achieving a micro-averaged F_1-score of 0.726.

Fodeh et al [44] collected 6988 opioid-related tweets, manually labeled them into 3 categories (No-OM, pain-related OM, and recreational OM), and applied NLP with multiclass machine learning classifiers. Using a held-out test set of 1677 tweets, XLNet achieved the best performance with F_1-scores of 0.71 (pain misuse) and 0.79 (recreational misuse) and macro– and micro–F_1-scores of 0.82 and 0.92, respectively. They also performed k-means clustering on terms, revealing distinct keyword clusters associated with each misuse category.

Ali and LoveJennifer [45] applied a machine learning classifier to identify Twitter users self-reporting nonmedical prescription drug use (NMPDU) and analyzed 137 million posts from 87,718 users using NLP. They found NMPDU users showed more negative and fewer positive emotions, with greater concerns about family and the past and less about work and health

XSL•FO
RenderX

compared to controls. Gender analysis revealed females expressed more positive emotions, anticipation, and health concerns than males across all drug categories.

Garg et al [46] manually labeled 391 Reddit posts using a clinical codebook of 12 fentanyl risk categories and trained machine learning models to detect risky content. Their best model achieved 76% accuracy and sensitivity in identifying posts indicative of fentanyl misuse. They also compiled a vocabulary of colloquial terms for fentanyl to aid future monitoring and interventions.

Preiss et al [47] developed a named entity recognition model to extract substances and effects from 4 million Reddit comments discussing opioid withdrawal and built a co-occurrence network to link remedies to symptoms. Their model achieved F_1-scores of 92.1 (substances) and 81.7 (effects), identifying 458 substances and 235 effects, with 41.5% of remedies being US Food and Drug Administration–approved and others potentially useful, natural, or harmful. They created the Withdrawal Remedy Explorer to enable further analysis, validating social media as a method for studying self-treatment behaviors.

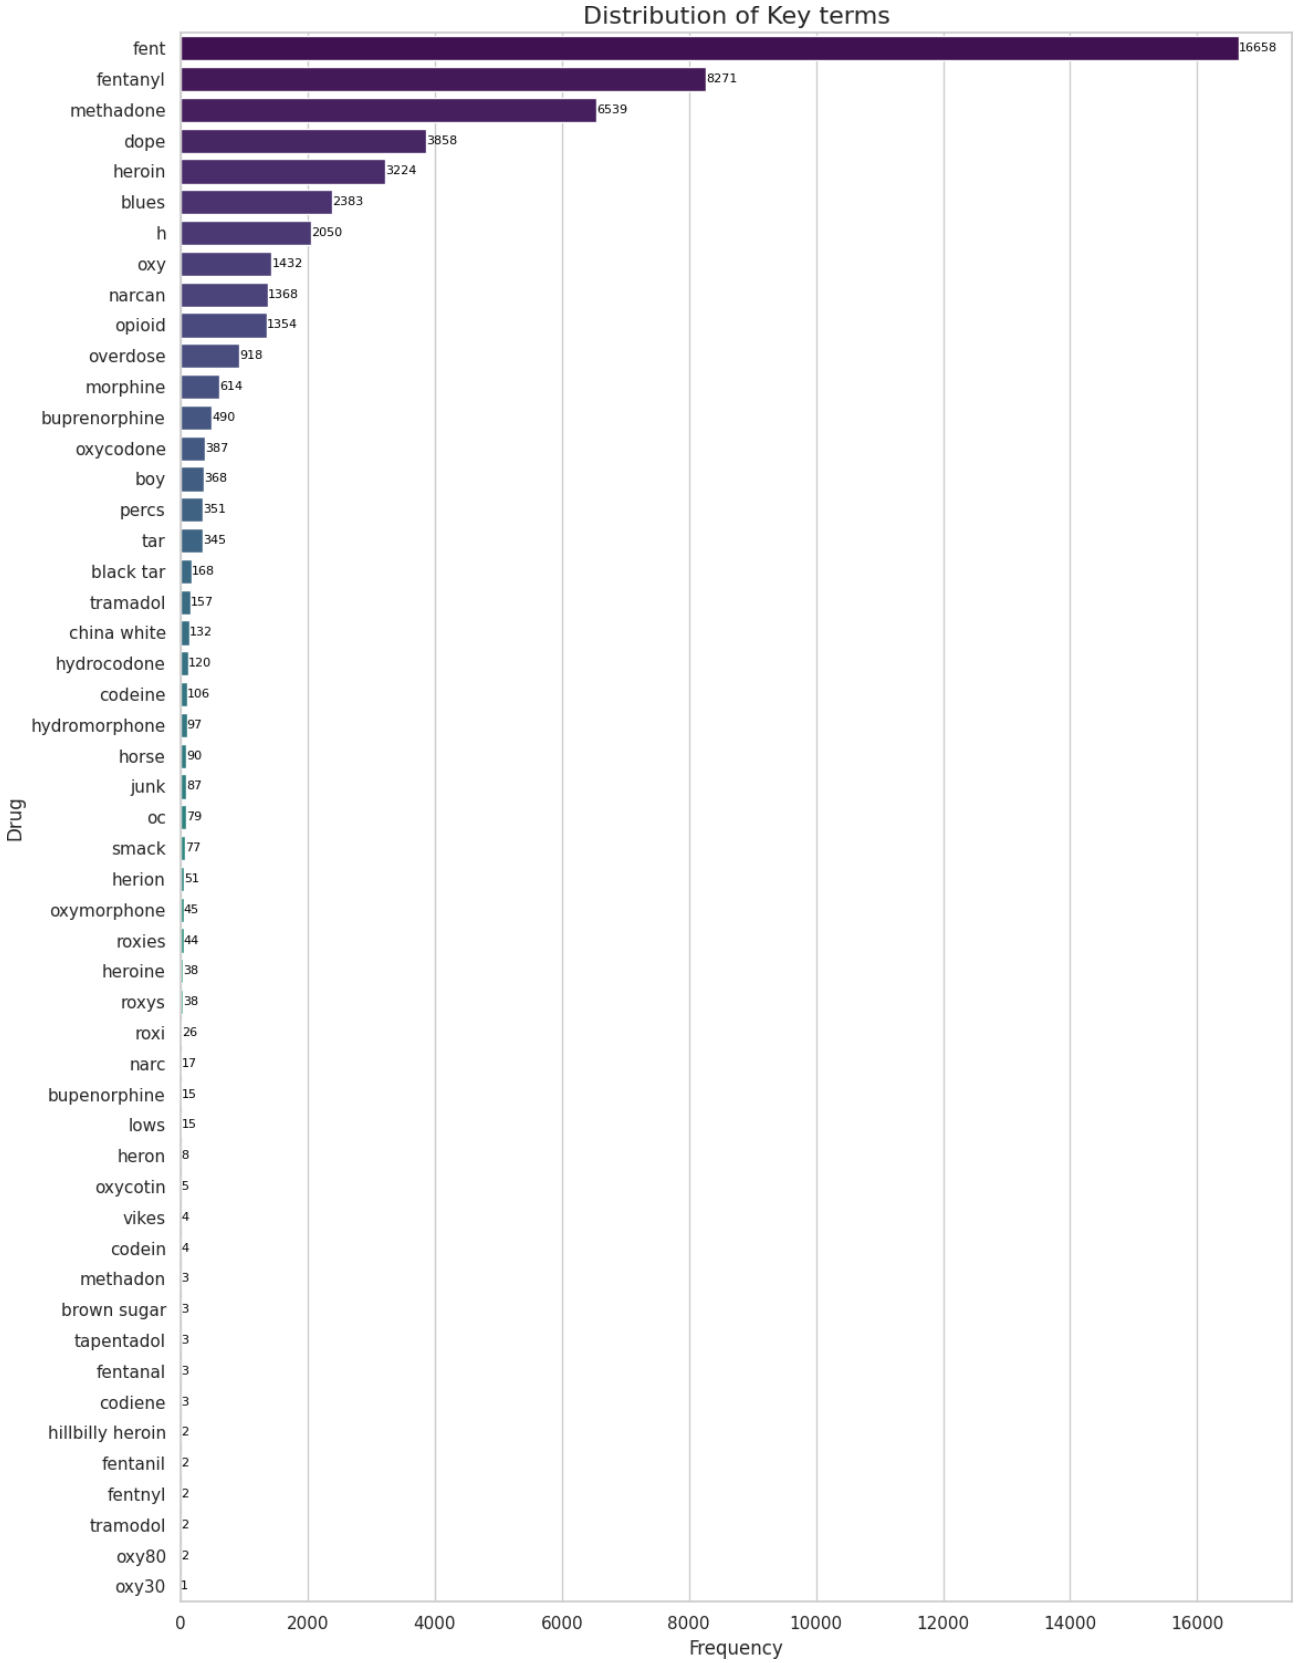
Yao et al [48] analyzed Reddit posts to detect suicidal ideation among opioid users using machine learning, training classifiers on data from suicide, depression, opioid-related, and control subreddits. The best model, a CNN, achieved an F_1-score of 96.6%, whereas neural network models outperformed traditional methods in minimizing false negatives when predicting posts combining opioid use and suicidality. This study shows that social media data and neural networks can help identify individuals at high risk for intentional overdose.

Smith et al [49] analyzed Reddit data to monitor opioid trends, creating a cohort of 1,689,039 users assigned to states and tracking opioid-related posts over time. Using an NLP pipeline, they compared Reddit trends with CDC overdose and NFLIS data, finding that adding real-time Reddit data improved the prediction of synthetic opioid overdose rates despite the CDC's 6-month reporting lag. The study shows Reddit can enhance timely surveillance of the opioid epidemic.

Unlike previous studies, including Sarkar et al [43], which focused on general abuse detection without distinguishing between types of misuse, our work develops a fully supervised NLP pipeline using both traditional machine learning and a fine-tuned LLM (GPT-3.5 Turbo) to classify Reddit posts into 4 detailed categories: self misuse, external misuse, informational, and unrelated. While prior studies often analyzed specific aspects such as pain versus recreational misuse by Fodeh et al [44], NMPDU behaviors by Ali and LoveJennifer [45], or fentanyl risk by Garg et al [46], our approach integrates multiple dimensions, spans 6 years of Reddit data, and incorporates temporal analyses. This enables not only higher classification accuracy (0.93) but also robust, scalable, and temporally informed monitoring of opioid-related social media discourse, providing a more comprehensive toxicovigilance system than previous work.

Methods

Construction of Dataset and Preprocessing



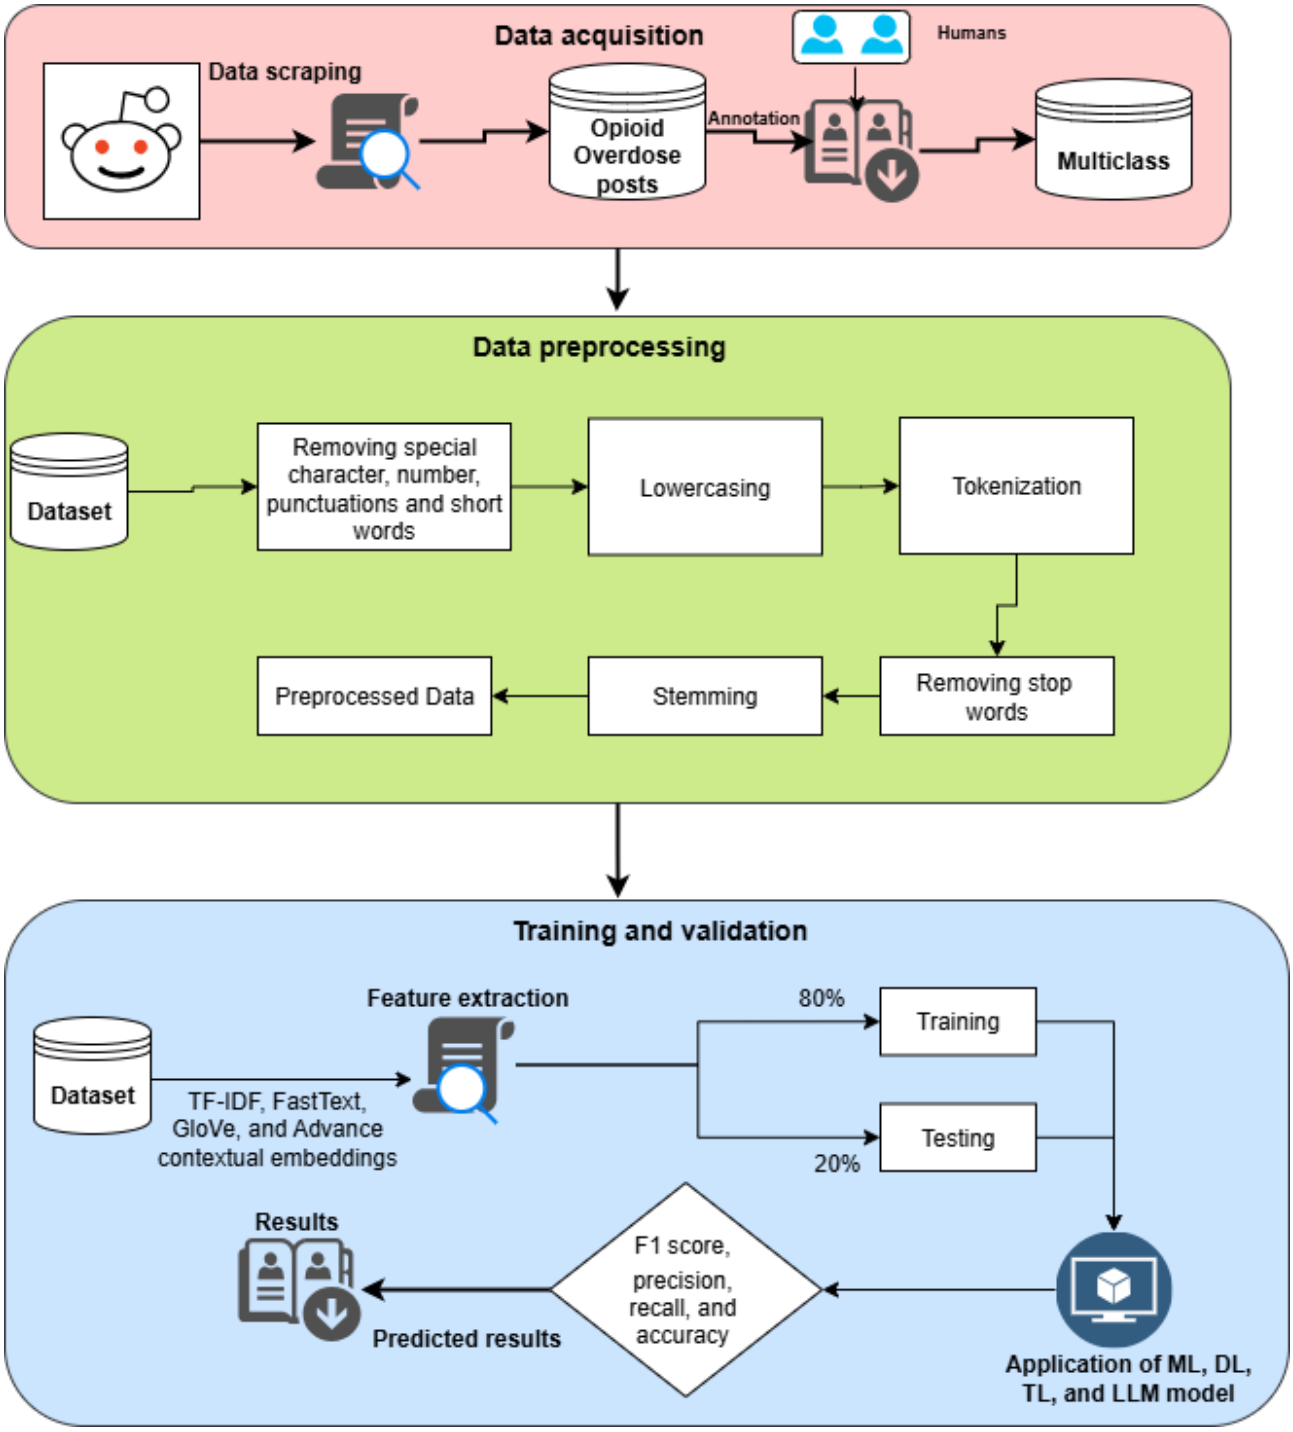
To construct a comprehensive dataset for analyzing opioid overdose discussions, we turned to Reddit, one of the most widely used online platforms where users openly share their personal health stories and experiences. Reddit is home to a range of communities, or subreddits, where users discuss various health-related topics, including substance use and recovery. Recognizing the value of real-world, user-generated content, we used Reddit's public application programming interface in combination with the Pushshift application programming interface to collect a substantial dataset of approximately 80,000 posts. The data, focused on mentions of opioid drugs and their overdose effects, were gathered between January 1, 2018, and December 30, 2023.

The data collection process spanned several relevant subreddits, such as r/opiates, r/OpiatesRecovery, r/addiction, and r/Drugs, which are known for hosting candid discussions about opioid misuse, addiction recovery, and overdose experiences. These subreddits provided a diverse range of conversations, from individuals sharing their personal struggles with addiction to those discussing family members' or friends' overdose incidents, as well as general awareness and information about opioids and related substances.

To ensure that the collected posts were relevant to the topic of opioid overdose, we implemented a keyword-based filtering system. We used a comprehensive set of nearly 50 carefully selected keywords, as shown in Figure 1, along with their word frequencies. These include formal terms such as "overdose," "opioid," "fentanyl," "heroin," "OxyContin," and "Narcan," as well as common slang and misspellings frequently encountered in social media discussions. Examples of slang and variations include "oxy," "narc," "fent," "dope," "smack," as well as misspellings such as "herin," "codein," "codiene," "herioin," "percacet," "fentnil," "fentnyl," "oxycontn," "oxocodien," and "narcan." This inclusive keyword list helped capture informal and colloquial references to opioids, reflecting the informal nature of Reddit conversations. Our keyword filtering also captured posts where opioid terms were used metaphorically, in usernames, or in unrelated contexts. These were manually labeled as unrelated during annotation to ensure dataset accuracy. Examples include phrases such as "@codeine_XXXX," "I am addicted to my X like fentanyl," or "Yoga and maple brown sugar roasted butternut squash." This step prevented irrelevant content from affecting the analysis.

XSL•FO
RenderX

Figure 1. Distribution of opioid-related keywords in a sample of 80,000 Reddit posts.



As social media platforms such as Reddit host multilingual communities, we applied language filtering to include only posts written in English. To ensure consistency and simplify analysis, we used a Python language detection library (eg, langdetect) to automatically identify and retain only English-language posts, excluding all non-English content from the dataset. This step ensured that the dataset accurately reflects English discussions relevant to our study.

After the construction of the dataset, we used some preprocessing steps to clean and standardize the text data for improved model performance. As our dataset was related to

XSL•FO
RenderX

opioid overdose discussions extracted from Reddit, it contained a lot of informal, noisy, and user-generated content that needed careful handling. Initially, we removed hashtags, emojis, and any embedded links to eliminate distractions and irrelevant symbols that do not contribute meaningfully to the actual content or context of the discussion. The next phase involved converting all text to lowercase to ensure uniformity, followed by expanding short or informal words into their full forms using the Python contractions library for standard English contractions (eg, “can’t” → “cannot,” “won’t” → “will not”). Finally, we removed posts with fewer than 15 characters, as they typically lacked meaningful information and could introduce noise into the analysis. These steps were crucial for ensuring the dataset was clean, consistent, and suitable for effective NLP, especially given the sensitive and critical nature of opioid-related discussions. Figure 2 presents the overall workflow of the proposed methodology.

Figure 2. . Proposed methodology and design. DL: deep learning; LLM: large language model; ML: machine learning; TF-IDF: term frequency–inverse document frequency; TL: transfer learning.

RenderX

Annotation

Annotation is the procedure of classifying data into predefined and meaningful information for supervised learning models. In our dataset, annotation involves labeling textual data into predefined binary classes that represent different aspects of opioid-related conversations. This helps machine learning models understand hidden patterns in drug abuse, detect trends, and train models for automated classification and analysis.

Data Annotation Guidelines

Following cleaning, the data were subjected to a rigorous manual annotation process. We defined 4 clear categories to label each post:

- Self-misuse: posts describing the Reddit opioid users' use of the drugs or overdose experiences by self or may include confessions, health complaints, withdrawal symptoms, or stories of addiction
- External misuse: posts discussing overdose or opioid use experienced by others (eg, friends, family, institutions, or social groups) or such as news, community issues, or government/policy critique
- Information: posts sharing factual data, advice, news articles, or general information about opioids and overdose or includes posts by health professionals, nongovernmental organizations, or automated bots sharing links or advice
- Not related: posts that mention keywords but are unrelated to opioid overdose

Annotation Process

In this study, the dataset was collaboratively created by the corresponding author with the assistance of 2 domain experts—PhD students in computer science—who had previously labeled the dataset. Their prior work on this dataset has been published, and they possess extensive experience in annotation within the opioid domain [34].

Initially, a subset of 500 Reddit posts was randomly selected for a pilot annotation phase to ensure a representative sample of opioid-related discussions. These posts were reviewed in collaboration with experts in addiction medicine to develop and refine the annotation guidelines. Each post was categorized into 1 of 4 predefined classes: self-misuse, external misuse, informational post, and not related (see section Data Annotation Guidelines). Table 1 provides examples for each category to illustrate the annotation criteria and support reproducibility. During this phase, all 3 annotators independently labeled the 500 posts to assess labeling quality and resolve discrepancies through discussion and majority voting. This iterative process facilitated refinement of the guidelines for improved clarity and consistency. After consensus on the guidelines, the remaining posts—bringing the total annotated dataset to 5046 posts—were labeled independently by all 3 annotators, following the finalized guidelines to maintain consistency across the dataset.

Table . Examples of opioid overdose taken from the dataset.

Reddit post	Class
Took way too many oxycodone tonight... feeling dizzy, can't breathe properly. My chest is so heavy. Should I be worried? #opioids #help	Self-misuse
My cousin keeps overdosing on fentanyl, but he refuses to go to rehab. I'm scared for him.	External misuse
Opioid overdoses are a major crisis. If you or someone you know is struggling, carry naloxone and seek help. Harm reduction saves lives! #EndOverdose	Information
She's my heroin—one smile from her and I'm gone. No rehab can fix this kind of addiction, and I don't even want to quit. #LoveAddiction	Unrelated

Interannotator agreement was assessed using Cohen κ and achieved a strong score of 0.82 across the entire set of annotated posts, indicating high reliability among annotators. This rigorous annotation process ensured that the dataset was accurately labeled and suitable for downstream classification tasks.

Corpus Characteristics and Standardization

Table 2 presents the label distribution in our annotated dataset before and after data augmentation. Initially, the dataset was imbalanced, with self-misuse having 1877 instances, whereas external misuse (1375 instances), information (1391 instances), and unrelated (403 instances) were underrepresented, resulting in a total of 5046 samples. To address this imbalance, we applied back-translation to augment the minority classes. Back-translation is a widely used technique in NLP [50,51] that enhances dataset diversity by translating text into an intermediate language and then translating it back to the original language. This process generates lexically and syntactically varied samples while preserving the original semantic meaning. Unlike simple duplication, back-translation introduces natural linguistic variation, helping the model generalize better. After augmentation, each class was expanded to contain 1877 instances, leading to a balanced dataset of 7508 samples, which supports more stable and unbiased model training.

XSL•FO
RenderX

Table . Label distribution of the proposed dataset before and after data augmentation.

Label	Before augmentation	After augmentation
External misuse	1375	1877
Information	1391	1877
Self-misuse	1877	1877
Unrelated	403	1877
Total samples	5046	7508

Table 3 provides a comprehensive overview of the linguistic characteristics of our final dataset after data augmentation, which consists of 7508 posts. The dataset contains a rich and diverse vocabulary of 25,993 unique words, reflecting the variety of expressions used across different user-generated texts. In total, the dataset comprises over 2.76 million characters, 603,107 words, and 23,615 sentences, indicating the substantial size and depth of the corpus. On average, each sentence contains approximately 17.68 words, which suggests moderately complex sentence structures, whereas each post contains about 5.23 words, highlighting the brevity typical of social media posts similar to those on Reddit. This combination of compact posts with meaningful linguistic diversity makes the dataset both challenging and valuable for training robust NLP models. Multimedia Appendix 1 shows the word cloud of our dataset.

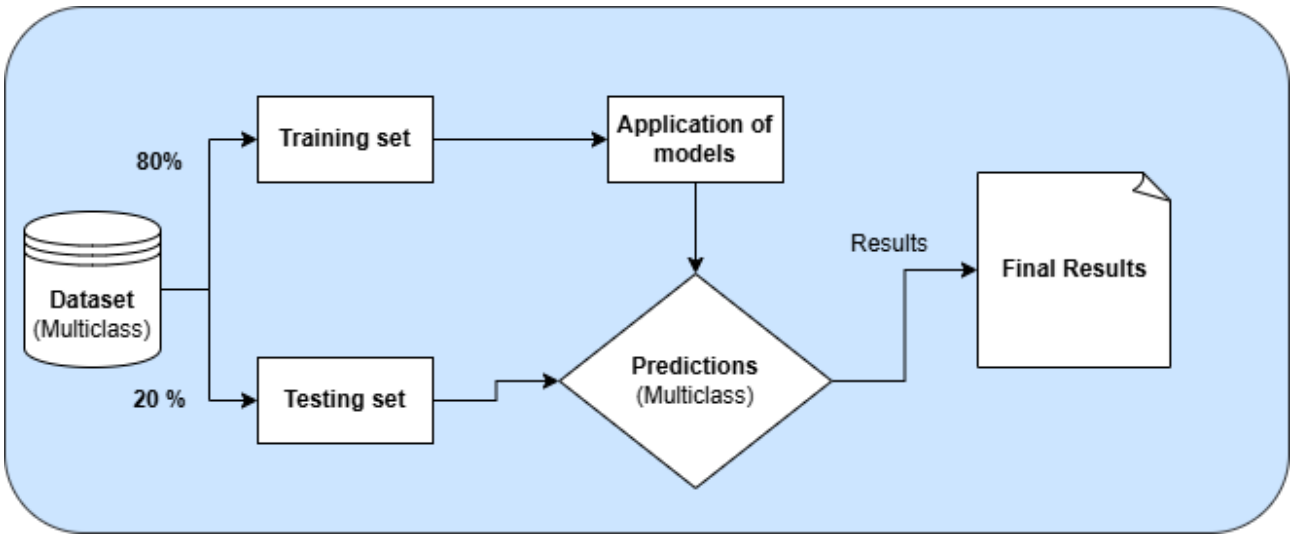

Table . Dataset statistics.

Metric	Value
Post	7508
Vocabulary	25,993
Total characters	2,762,238
Total word	603,107
Total sentence	23,615
Average words per sentence	17.679
Average words per post	5.23

Application of Models Training and Testing

In this section, we explain the application of the models during the training and testing phases. Figure 3 presents a detailed pipeline for a multiclass classification task using a variety of machine learning, deep learning, transformer-based models, and LLMs. The process begins with a multiclass dataset, which is divided into 2 parts: 80% of the data are allocated for training the models, whereas 20% are held out as an independent testing set for evaluating performance. This 80‐20 split was consistently applied across all models to ensure uniformity in data handling.

Figure 3. Application of models training and testing phase.

The training phase involves applying multiple types of models across 4 main categories. In traditional machine learning, models such as RF, XGB, SVM, and LR are trained using TF-IDF features to capture term importance. For deep learning, architectures such as CNN and BiLSTM are used, supported with pretrained word embeddings, such as FastText and GloVe,

XSL•FO
RenderX

to better capture semantic relationships in text. The pipeline also incorporates powerful transformer-based models, including XLM-R, DistilBERT, mBERT, and Bio_ClinicalBERT, all of which are fine-tuned to adapt to the dataset. These transformer-based models leverage contextual understanding from large-scale corpora. In addition, an LLM, GPT-3.5-turbo-0125, is fine-tuned (Table 2), using its advanced natural language understanding capabilities. LLMs generate high-quality contextual embeddings that capture deep semantic and syntactic information, enabling a more accurate and nuanced understanding of language compared to traditional embedding methods.

Once all models are trained, they are evaluated on the held-out testing set, generating multiclass predictions. These predictions are then compiled and analyzed to assess accuracy, precision, recall, and F_1-scores. The results from each category of models help determine which methods are most effective for the task. This comprehensive approach enables a comparative analysis across model types.

Owing to the significant computational resources and financial costs associated with fine-tuning LLMs such as GPT-3.5, cross-validation or separate validation sets were not feasible. Instead, hyperparameter tuning and model selection were conducted exclusively on the training data, whereas the held-out test set was strictly reserved for final unbiased evaluation.

In the final stage, the top-performing model was deployed on an unlabeled dataset comprising 74,975 additional Reddit posts. This enabled a detailed temporal analysis of opioid-related discussions over the 6-year period, uncovering trends and shifts in public perception, self-reported use, and information sharing around opioid drugs.

Table 4 summarizes the hyperparameter tuning settings applied during model training for each learning approach, such as LLM, transformers, machine learning, and deep learning—in the context of a multiclass classification task on opioid overdose data. Hyperparameter tuning was conducted using grid search exclusively on the training set, following an 80% to 20% train-test split, as detailed in the model training section. No separate validation set was used; instead, all parameters were optimized within the training partition to avoid data leakage and ensure generalization. For the LLM, GPT-3.5-turbo-0125 was tuned with parameters such as epochs (3), batch size (12), learning rate (2), seed (1278387729), and processed 1,761,342 tokens, reflecting the scale and reproducibility of fine-tuning. The transformer models, including mBERT, Bio_ClinicalBERT, DistilBERT-base-uncased, and XLM-R, were optimized using a learning rate of 2e-5, 3 epochs, batch size of 32, and trained with the AdamW optimizer and CrossEntropyLoss, a typical setup for classification tasks using pretrained language models. The machine learning models had distinct tuning schemes: SVM used random state (42), kernels (linear and RBF), C (1.0), and gamma (auto); XGB was tuned with 100 estimators, max depth (6), and learning rate (0.3); RF used standard parameters such as n_estimators (100), max_depth (none), and bootstrap (true) to control the number and depth of trees and sampling behavior; and LR used random state (42), max iterations (1000), C value (0.1), and the liblinear solver. Finally, the deep learning models (BiLSTM and CNN) were trained using a learning rate of 0.1, 5 epochs, an embedding dimension of 300, and a batch size of 32, suitable for word embedding–based architectures. These hyperparameter settings were selected through grid search to systematically explore model performance variations.

Ethical Considerations

This study involved the creation of a novel annotated dataset using publicly available text posts from Reddit. Only content that was freely accessible without any login or private access was collected, and no interaction with users occurred. All data were processed in accordance with Reddit's terms of service, and personally identifiable information was removed before annotation. As the study used publicly available, nonidentifiable content and presented results in aggregate, institutional review board or equivalent ethics approval was not required.

Results

Overview

In this section, we present the experimental results obtained using machine learning, deep learning, transformer-based models, and LLMs, following the methodology outlined in the previous section.

Machine Learning Results

We used several machine learning models to get a full picture of how diverse algorithms performed on our dataset. Owing to the various strengths and assumptions of individual models, the set of varied models will help in drawing a better and trustworthy analysis. This comparative approach helps identify which model performs best for our specific task and ensures that the results are not biased toward a single algorithm's limitations.

Table 5 presents the performance of 4 different machine learning models—such as LR, RF, SVM, and XGB—applied to a multiclass classification task on opioid-related social media chatter using TF-IDF. TF-IDF was used as a feature extraction technique to convert unstructured text into numerical features that machine learning models can understand and process. It helps highlight words that are important and meaningful in a specific document while minimizing the influence of commonly used words that may not carry significant context. The task involves categorizing Reddit chatter posts into 4 distinct classes: self-misuse, external misuse, informational content, and unrelated posts. Each model's effectiveness is measured using 4 standard metrics: precision, recall, F_1-score, and accuracy. Among the models, the RF achieved the highest performance across all metrics (0.85), indicating superior capability in correctly identifying various opioid-related classes in the dataset. XGB followed closely with scores of 0.83, suggesting it also performed well in handling the complexity of multiclass distinctions in social media text. SVM and LR trailed behind, with SVM scoring 0.79 and LR the lowest at 0.77 across all metrics. This evaluation suggests that ensemble models such as RF and XGB are more effective in understanding and classifying nuanced opioid-related discourse on social platforms compared to linear and margin-based methods.

[c]SVM: support vector machine.

[d]XGB: Extreme Gradient Boosting.

Deep Learning Results

Table 6 compares the performance of 2 popular deep learning models—such as CNN and BiLSTM—using 2 different pretrained word embedding techniques, FastText [52] and GloVe [53], for classifying opioid-related social media chatter for the classification of opioid-related Reddit posts into 4 categories, including self-misuse, external misuse, informational content, and unrelated posts. We used these word embeddings to capture the semantic meaning of words based on their usage in large corpora, allowing models to understand the context and relationships between words more effectively. When using FastText embeddings, the CNN model outperforms BiLSTM, achieving the highest scores across all metrics with a precision of 0.82, recall of 0.80, F_1-score of 0.79, and accuracy of 0.80. In contrast, the BiLSTM underperforms with slightly lower values. With GloVe embeddings, both CNN and BiLSTM perform similarly, with CNN achieving a slight edge in recall and accuracy (both 0.79) compared to BiLSTM (0.78). Overall, FastText embeddings combined with CNN yielded the best performance, suggesting that FastText's subword-level information is more effective in capturing linguistic nuances in opioid-related discussions, especially when processed with CNN's ability to extract local patterns in text.

Table . Results for deep learning models.

Model	Precision	Recall	F_1-score	Accuracy
FastText				
CNN[a]	0.82	0.8	0.79	0.8
BiLSTM[b]	0.77	0.76	0.76	0.76
GloVe				
CNN	0.79	0.79	0.78	0.79
BiLSTM	0.79	0.78	0.78	0.78

[a]CNN: convolutional neural network.

[b]BiLSTM: bidirectional long short-term memory.

Transformer Results

We have used transformer models, as they better comprehend the meaning and contextual relationships of words within a sentence compared to the models used in the previous sections, such as machine learning and deep learning approaches. Their ability to capture complex dependencies within the text contributes to improved performance, particularly in the classification of challenging and nuanced textual data [54].

Table 7 evaluates transformer-based language models—XLM-R, DistilBERT, mBERT, and Bio_ClinicalBERT—on their performance in classifying opioid-related social media chatter in a multiclass scenario. Among these, XLM-R and mBERT deliver the top results, each achieving a high F_1-score and accuracy of 0.89, with XLM-R slightly leading in precision (0.90). These results highlight their strong capability in handling multilingual or diverse language patterns often found in social media discussions. DistilBERT and Bio_ClinicalBERT also perform well, scoring 0.88 across all metrics, but fall just short of the leading models. Interestingly, despite Bio_ClinicalBERT being pretrained on clinical texts, it does not outperform general-purpose multilingual models in this context, possibly due to the informal, varied nature of social media language. Overall, XLM-R and mBERT emerge as the most effective models for understanding and classifying opioid-related content in a multilingual, user-generated text environment.

[b]mBERT: multilingual bidirectional encoder representations from transformers.

LLM Results

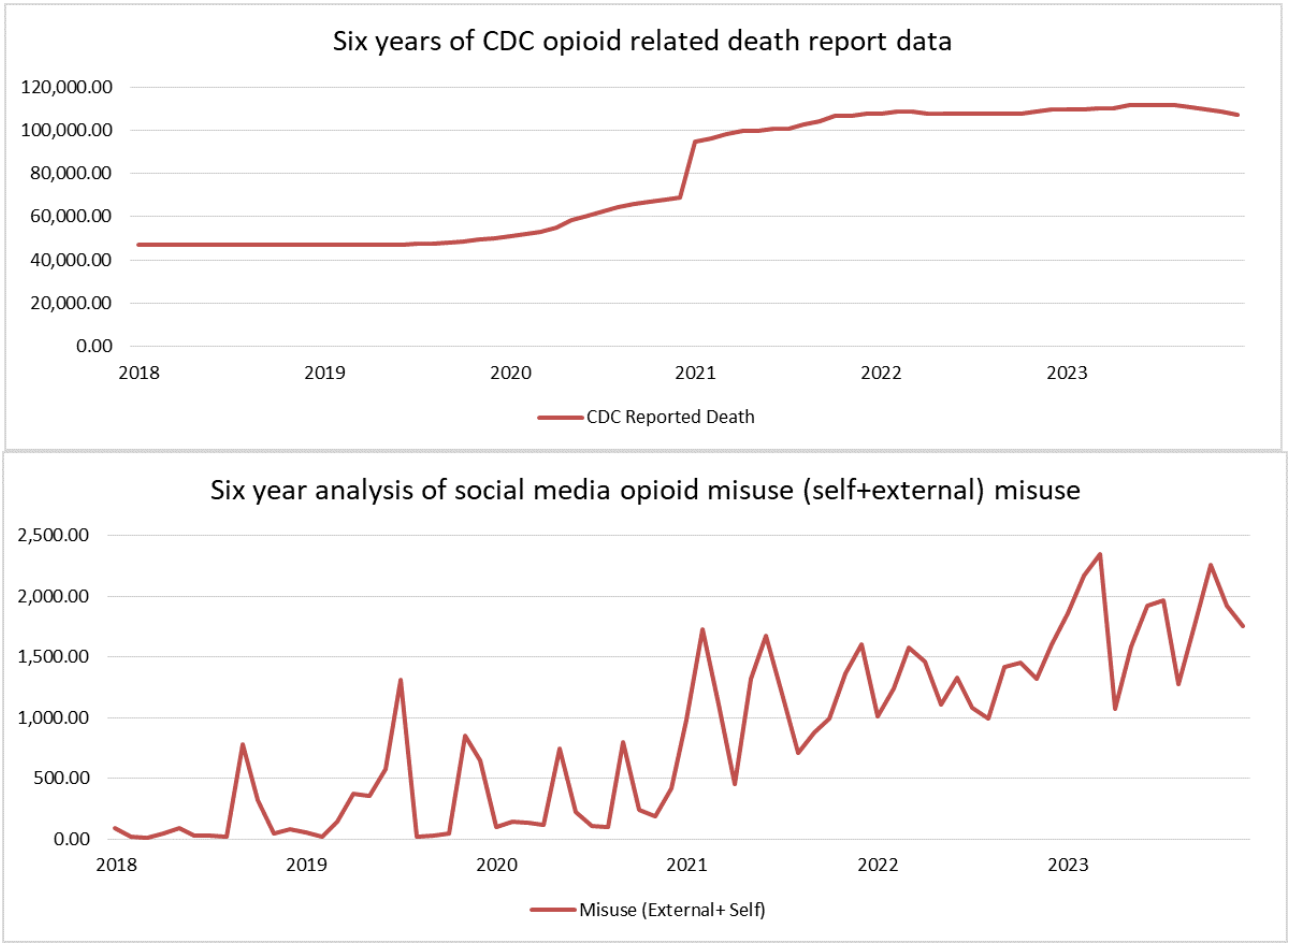
Table 8 presents how well GPT-3.5 Turbo performed on a multiclass classification task focused on opioid-related social media chatter, with categories such as self-misuse, external misuse, information, and not related. On the training set, the model scored almost perfectly with 97% precision, recall, F_1-score, and accuracy, meaning it could accurately distinguish between people talking about their own misuse, others' misuse, sharing informational content, or unrelated topics. When tested on unseen data, it still performed strongly with 93% across all metrics, showing that it generalizes well and can reliably interpret real-world conversations without major overfitting. This strong performance indicates the model can effectively support tasks such as public health monitoring or early detection of opioid misuse trends by correctly categorizing social media discussions into these nuanced classes.

Table . GPT-3.5-turbo performance on multiclass opioid-related social media classification in training and test datasets.

Model	Precision	Recall	F_1-score	Accuracy
XLM-R[a]	0.9	0.89	0.89	0.89
DistilBert	0.89	0.88	0.88	0.88
mBERT[b]	0.89	0.89	0.89	0.89
Bio_ClinicalBERT	0.88	0.88	0.88	0.88

[a]XLM-R: XLM-RoBERTa.

[b]mBERT: multilingual bidirectional encoder representations from transformers.



We used GPT-3.5 Turbo in this task because it is a powerful, general-purpose language model capable of understanding nuanced, context-rich data—such as informal and diverse social media posts [55]. Unlike traditional classifiers, GPT-3.5 Turbo can leverage deep semantic understanding and contextual reasoning, which is particularly useful for the ambiguous and unstructured language commonly found in online discussions about opioids.

Temporal Analysis

Figure 4A presents the official mortality records over a 6-year period [56], whereas Figure 4B shows the volume of misuse-related posts (combined external and self) and informational posts related to substance use during the same time frame. To conduct the temporal analysis of opioid abuse, we trained our top-performing model (GPT-3.5) on 74,975 unlabeled posts, classifying them into 4 key categories: self-misuse, external misuse, information, and unrelated.

XSL•FO
RenderX

Figure 4. Trends in opioid-related CDC mortality and social media discourse from January 1, 2018, to December 30, 2023. CDC: Centers for Disease Control and Prevention.

From 2018 to 2023, the temporal trends of Reddit misuse-related discussions show a striking alignment with the CDC's opioid-related death statistics, suggesting that social media discourse mirrors real-world shifts in the opioid crisis. In the early years (2018 - 2019), both misuse post volumes and CDC deaths remained comparatively lower and more stable, with occasional local spikes such as September and October 2018, where misuse posts surged to 780 and 324, respectively, despite steady death counts around 47,000. However, starting mid-2019, sharp increases in misuse chatter emerged, most notably in June (580 posts) and July (1310 posts), which preceded or coincided with gradual rises in reported deaths—indicating that online communities may detect or reflect growing misuse patterns ahead of official mortality escalation.

The year 2020 marks a turning point. Amid the COVID-19 pandemic, both misuse posts and CDC deaths began climbing in parallel, with significant peaks in May (750 misuse posts and ~58,640 deaths) and September (796 misuse posts and ~65,811 deaths). This synchronous growth continued into 2021, where both metrics reached unprecedented levels. February 2021 saw 1728 misuse posts alongside 96,118 deaths, followed by sustained high activity through the year, culminating in December with 1600 misuse posts and 107,573 deaths. Notably, the temporal curves for 2021 suggest a near one-to-one relationship—when misuse posts rose, deaths also trended upward, reinforcing the notion that digital discourse intensity is tightly coupled with public health outcomes.

From 2022 onward, the pattern persisted but with even higher baselines. Monthly misuse counts regularly exceeded 1000, with peaks such as March 2022 (1576 misuse posts and 108,604 deaths) and December 2022 (1600 misuse posts and 109,413 deaths). In 2023, the relationship became even clearer: February's 2167 misuse posts coincided with 109,714 deaths, whereas March reached the dataset's highest misuse level at 2345 posts alongside 110,084 deaths. Although CDC death counts plateaued toward late 2023, misuse posts remained elevated, suggesting sustained concern and conversation within online communities even when mortality rates slightly dipped.

To quantify this relationship, we calculated the Pearson correlation coefficient (r=0.854) and the corresponding P-value (P<.001). These results indicate a strong positive correlation between Reddit misuse posts and CDC death records, which is statistically highly significant, confirming that the observed alignment is unlikely due to chance.

Overall, the temporal comparison indicates that Reddit discussions—particularly misuse-related categories—tend to rise and fall in close alignment with CDC mortality trends, sometimes even leading them. This finding underscores the value of social media monitoring as a complementary, potentially more immediate signal for detecting shifts in the opioid crisis, enabling earlier interventions before official data fully reflects the magnitude of the problem.

XSL•FO
RenderX

Error Analysis

Table 9 presents the results of the top-performing models in each learning approach. The RF model delivered the best results in the traditional machine learning setting since it reached 0.85 in precision, recall, F_1-score, and accuracy. It is implied by its regular outcomes that RF is very efficient in recognizing the patterns in structured data on the basis of opioid-related discussions. RF has an ensemble nature that enables generalization, and therefore, it acts well in the case of an engineered dataset with moderate complexity.

Table . Top-performing models in each learning approach.

Model	Precision	Recall	F_1-score	Accuracy
RF[a]	0.85	0.85	0.85	0.85
CNN[b] (FastText)	0.82	0.8	0.79	0.8
XLM-R[c]	0.9	0.89	0.89	0.89
GPT-3.5	0.93	0.93	0.93	0.93

[a]RF: random forest.

[b]CNN: convolutional neural network.

[c]XLM-R: XLM-RoBERTa.

When using the deep learning models with FastText and GloVe, the CNN using the FastText embeddings proved most effective. The model achieved a highest F_1-score of 0.79 and an accuracy of 0.80. This pairing demonstrates the importance of both word representation and architecture when processing short, varied user-generated content.

In transformer-based models, the XLM-R model performed the best with a score of 0.89 (F_1-score) and accuracy of 0.89. It is also an appropriate tool to work with different language patterns on social media because of its multilingual training and well-developed contextual awareness. It performed better than other transformer models, including mBERT and DistilBERT, which means that it is strong in inferring subtle behavioral cues about the users talking about opioids.

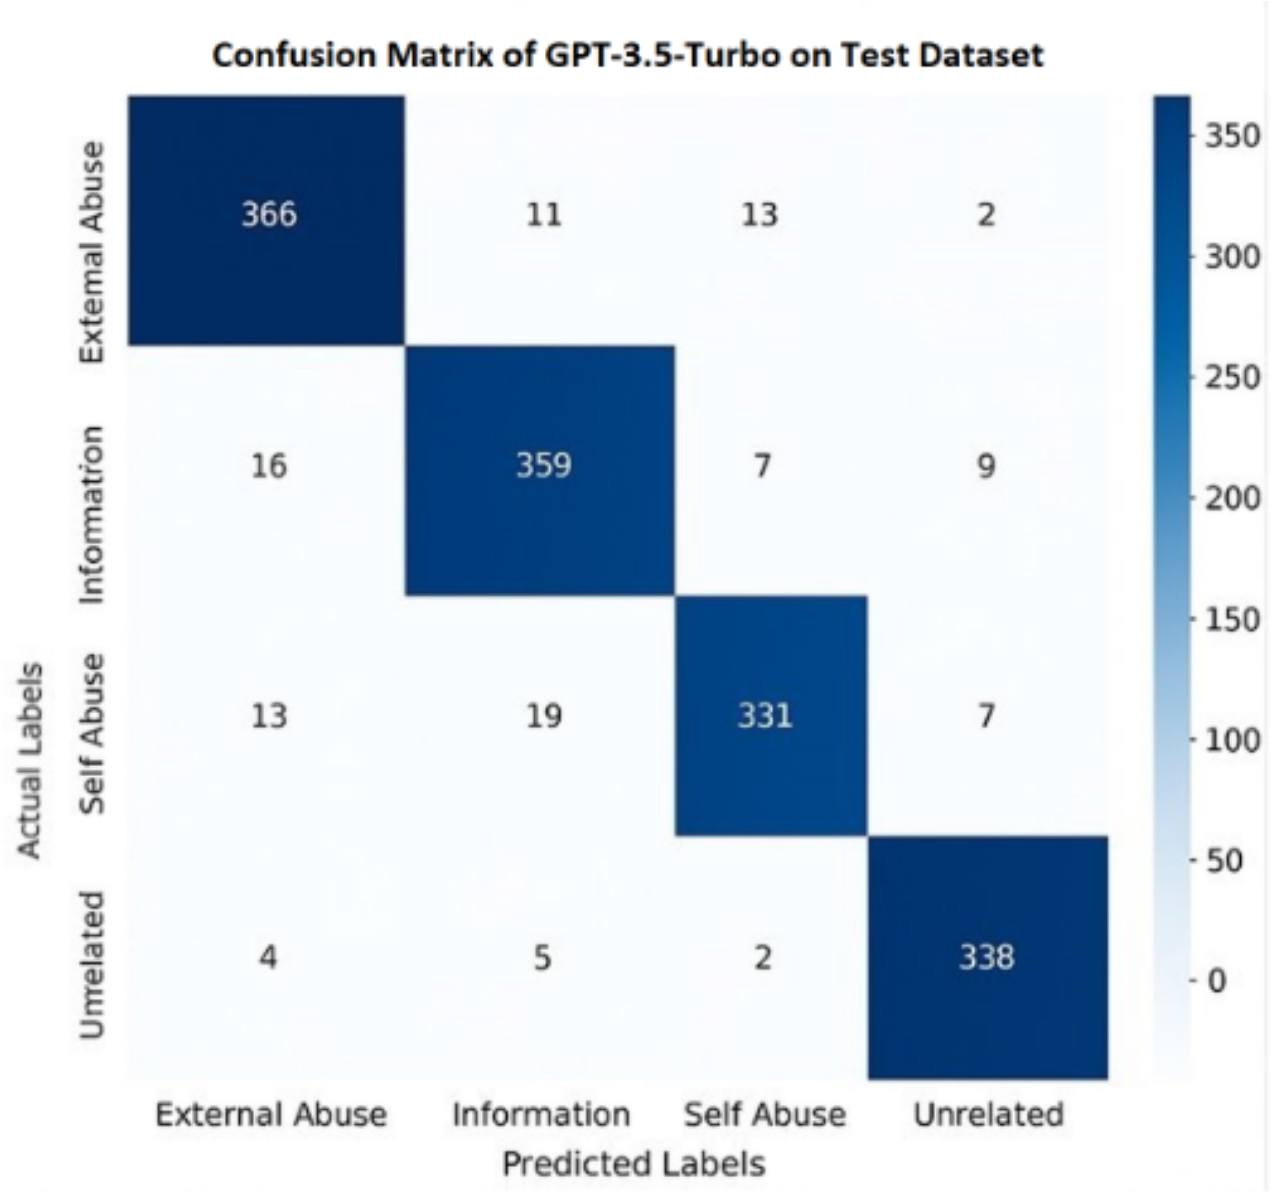
GPT-3.5 Turbo demonstrated the best performance among all models, achieving a score of 0.93 across all evaluation metrics, including precision, recall, F_1-score, and accuracy. This consistent and high performance highlights the model's effectiveness in handling the classification task. The reason why this LLM is exemplary is that it has a deep sense of understanding, few-shot reasoning capacities, and generalization skills over complex, input-rich scenarios. The high performance indicates the increasing potential of generative models in supporting the real-world and multiclass classification problems that deal with such sensitive and subtle issues as the behavior of opioid use.

Table 10 provides a detailed breakdown of GPT-3.5 Turbo's performance in classifying opioid-related social media posts into 4 distinct categories: external misuse, information, self-misuse, and unrelated on the training and testing datasets. These categories represent different contexts of opioid discussions: External misuse refers to posts about others misusing opioids, information includes educational or factual content, self-misuse captures individuals sharing their own misuse experiences, and unrelated denotes content not relevant to opioids. Each category was evaluated using standard metrics—precision, recall, and F_1-score—along with support, which indicates the number of posts in each category.

Table . Class-wise score of the GPT-3.5-turbo model on training and test datasets.

Category	Precision	Recall	F_1-score	Support
Test set				
External misuse	0.92	0.93	0.93	392
Information	0.91	0.92	0.91	391
Self-misuse	0.94	0.89	0.92	376
Unrelated	0.95	0.97	0.96	343
Training set				
External misuse	0.97	0.98	0.97	1506
Information	0.97	0.96	0.97	1498
Self-misuse	0.96	0.97	0.97	1502
Unrelated	0.99	0.97	0.98	1500

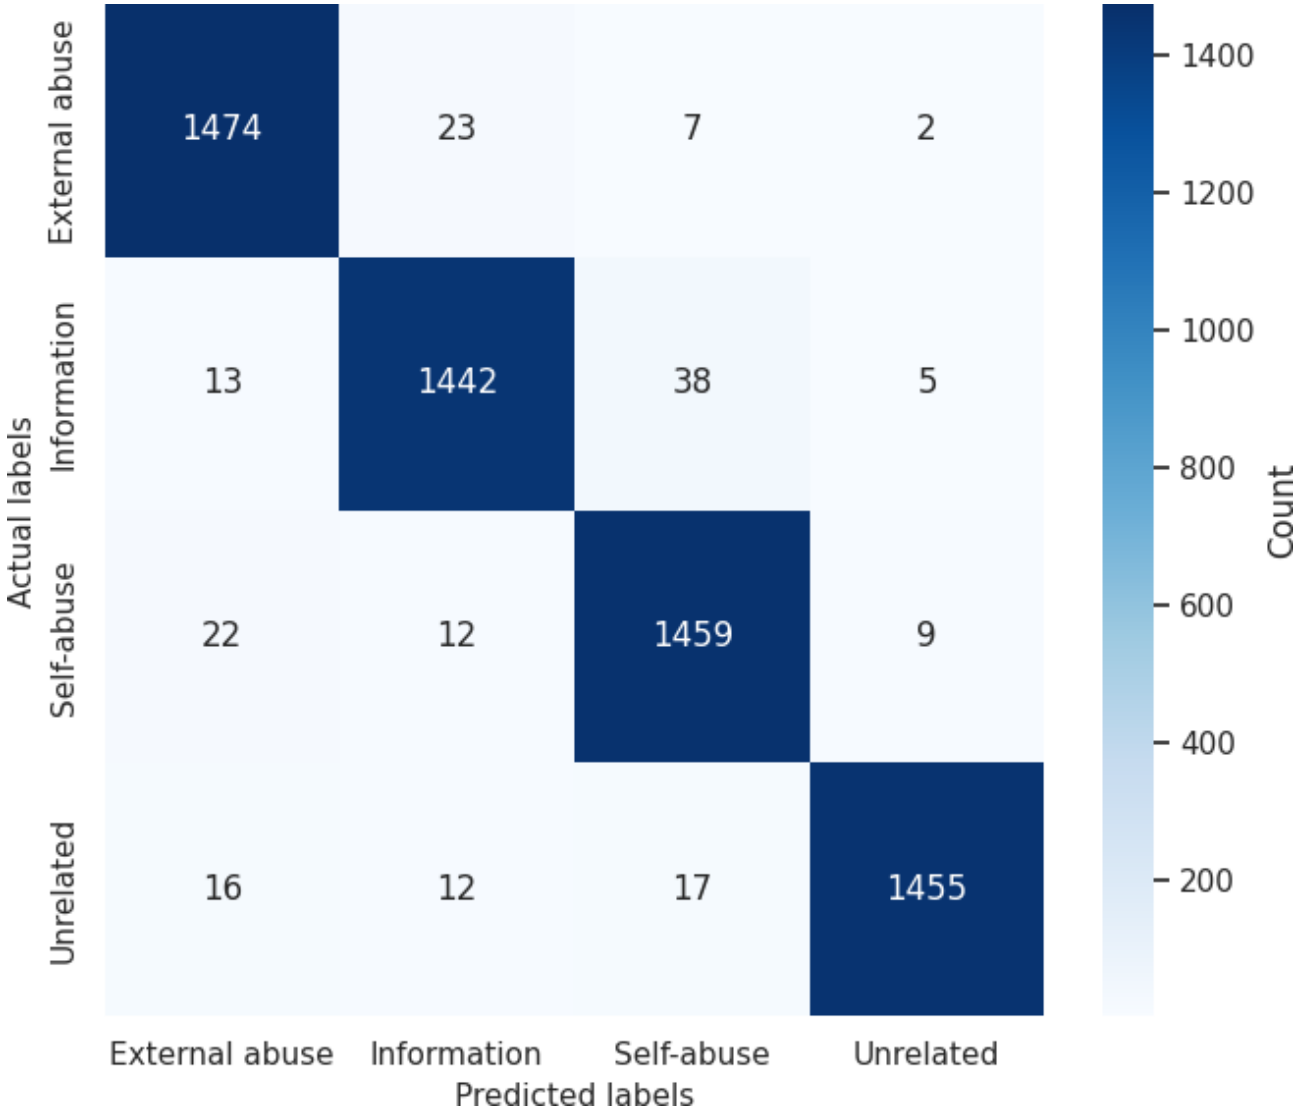
On the training set, GPT-3.5 Turbo demonstrated near-perfect performance, indicating strong learning of the patterns in the data. Precision and recall for most categories were extremely high, ranging from 0.96 to 0.99, and the F_1-score was similarly



XSL•FO
RenderX

impressive, with unrelated posts scoring the highest at 0.98. For example, external misuse, information, and self-misuse each achieved an F_1-score of 0.97, reflecting the model's ability to balance correctly identifying relevant posts while minimizing misclassification. These results suggest the model adapted well during training and could easily distinguish between nuanced content types.

On the test set, which reflects the model's ability to generalize to unseen data, GPT-3.5 Turbo continued to perform strongly, although slightly lower than the training results—a normal and expected trend when models move from training to real-world scenarios. The F_1-scores ranged from 0.91 to 0.96, indicating excellent generalization. Among the categories, unrelated posts were classified with the highest accuracy (F_1-score=0.96), while self-misuse scored slightly lower (F_1-score=0.92). This small dip may be because of the complexity and subtlety of personal language used in self-disclosure posts, which can be harder to interpret than factual or unrelated content. External misuse and information categories both performed well with F_1-scores of 0.93 and 0.91, respectively, showing that the model handled context-based distinctions effectively.



Overall, these results highlight GPT-3.5 Turbo's strength as an LLM in handling a sensitive and nuanced classification task. Its high precision and recall mean it can accurately detect opioid-related discussions while avoiding misclassifications, which is critical for real-world applications such as public health surveillance, early detection of misuse trends, and guiding harm reduction strategies. The slight drop from training to test performance confirms that the model is well-generalized without severe overfitting, making it a reliable tool for practical deployment in opioid-related content monitoring. We plotted the confusion matrices for both the training and testing sets. Figure 5 shows the confusion matrix for the test set, whereas Figure 6 shows the confusion matrix for the training set. The confusion matrix is a performance evaluation tool used for classification models. It helps us understand how well the model is performing by showing the breakdown of correct and incorrect predictions across the various classes.

Figure 5. Confusion matrix of GPT-3.5-Turbo model on the test set.

Figure 6. Confusion matrix of GPT-3.5-Turbo model on the training set.

Discussion

Principal Findings

This study presents a comprehensive comparison of various machine learning, deep learning, transformer, and LLMs to classify opioid-related social media chatter into 4 behavioral categories: self-misuse, external misuse, informational, and unrelated. Among traditional models, RF emerged as the best performer, achieving an F_1-score of 0.85. In deep learning, the CNN model using FastText embeddings outperformed other configurations with an F_1-score of 0.79. Transformer-based models, particularly XLM-R, delivered high accuracy and contextual understanding with an F_1-score of 0.89. However, the GPT-3.5 Turbo model demonstrated the best overall performance across all learning approaches, achieving a perfect balance across all metrics (0.93), likely because of the balanced nature of the dataset and its advanced contextual reasoning abilities. The class-wise analysis further confirmed that GPT-3.5 Turbo is highly effective across all categories, with particularly strong performance in identifying unrelated and external misuse content. These findings highlight the increasing value of LLMs in toxicovigilance and behavior monitoring on social media platforms, particularly in sensitive domains such as opioid use.

Comparison to Prior Work

While prior research, such as that by Webster et al [36], Dekeseredy et al [37], and Jaafar [41], has provided critical qualitative insights into media portrayals, stigmatizing narratives, and public discourse on opioid use, these studies often relied on manual analysis and lacked scalable frameworks for real-time monitoring. Some recent efforts used unsupervised methods to analyze opioid-related posts; however, they faced challenges such as noise, irrelevant content, and limited interpretability. In contrast, this study fills a critical gap by implementing a robust, supervised NLP pipeline, combining the power of pretrained embeddings and LLMs to enhance classification accuracy. Compared to earlier works that offered descriptive insights or small-scale automated models, the use of GPT-3.5 Turbo and transformer architectures in this study significantly improves the granularity, scalability, and reliability of opioid discourse classification. Furthermore, the inclusion of temporal analysis distinguishes this work by allowing researchers and policymakers to track behavior and crisis trends

XSL•FO
RenderX

over time, an area not sufficiently addressed in previous literature.

Strengths and Limitations

One of the key strengths of this study is its comprehensive evaluation across a broad range of models, from traditional machine learning to state-of-the-art LLMs. The balanced, manually annotated dataset, developed in collaboration with domain experts, provides a reliable foundation for multiclass classification and ensures consistency in labeling. The integration of temporal analysis using Reddit posts from 6 years further enhances the utility of this system for real-time public health surveillance. Moreover, the use of GPT-3.5 Turbo demonstrates the transformative potential of LLMs in extracting behavioral insights from noisy, user-generated data.

However, several limitations remain. First, the dataset, while diverse and balanced, is limited to Reddit and may not capture the full spectrum of discourse across other platforms such as Facebook, X, or TikTok. Second, while the dataset was perfectly balanced across classes, real-world social media data are often highly imbalanced, with many more "unrelated" posts than posts in other categories. This balancing decision improves model performance on all classes but may reduce generalizability to broader, naturally imbalanced datasets. Third, the model assigns only a single label per post, whereas in reality, a post may contain elements of multiple categories, for example, "I've been taking more oxycodone than my doctor prescribed because the pain is still bad, but I also read about overdose risks and want to warn others to be careful." This single post includes aspects of self-misuse, external misuse, and informational content. When such posts are restricted to 1 label, important nuances may be lost. As a result, some nuances of user behavior may be lost when posts are forced into a single category.

Fourth, this study does not incorporate advanced geolocation techniques, such as user profile analysis and language-geography inference, which could enable more precise identification of posts originating from the United States—the primary country of interest in this study—as well as broader regional analysis. Integrating these techniques in future work may provide deeper insights into the geographical distribution of opioid-related discourse. Fifth, the model's slightly lower recall in the self-misuse category suggests a need for more nuanced linguistic and contextual modeling in this area. In addition, although LLMs such as GPT-3.5 are powerful, they are computationally expensive and require significant resources to fine-tune or deploy at scale. Finally, while the model performs well in classification, it does not yet explain the underlying drivers or sentiment trends behind opioid behavior—areas that could be explored in future work.

Conclusions and Future Work

This study demonstrates the significant potential of social media platforms, particularly Reddit, as valuable sources for real-time opioid surveillance through NLP and advanced machine learning techniques. By leveraging a large-scale annotated dataset and applying a range of supervised and transformer-based models, including fine-tuned LLMs, we classified opioid-related discourse into meaningful categories and uncovered temporal trends that align with known patterns in the ongoing opioid crisis. Our proposed supervised model, trained on manually annotated Reddit data, outperformed traditional unsupervised and baseline transformer models, achieving a classification accuracy of 0.93—a 9.16% improvement over classical machine learning model (RF 0.85). These results underscore the effectiveness of supervised learning, particularly when coupled with high-quality annotation and domain-specific preprocessing, in handling noisy and unstructured social media text. Moreover, the temporal analysis of 6 years of opioid-related chatter highlighted evolving patterns of public engagement, including spikes likely influenced by media coverage, policy changes, and societal events. Correlation analysis showed that misuse-related posts were strongly associated with CDC-reported deaths (Pearson r=0.854, P<.001), indicating that social media activity closely mirrors real-world mortality trends.

Although our proposed system has demonstrated strong performance in classifying opioid-related discussions and capturing temporal trends, several avenues remain for future exploration. First, expanding the analysis to include additional social media platforms, such as X (formerly Twitter), YouTube, and Facebook, could provide a more comprehensive view of online opioid-related discourse. Second, incorporating advanced geolocation techniques, such as user profile analysis and language-geography inference, could enable more precise country-specific and regional analysis, offering deeper insights into the geographical distribution of opioid-related discussions. Third, incorporating multimodal data—such as images, videos, and audio—may further enhance the system's ability to detect signs of substance abuse. Third, improving the model's ability to handle code-mixed and multilingual data will be essential for capturing opioid-related discussions in diverse linguistic communities. In addition, integrating geolocation inference techniques could support finer-grained spatial analyses, helping to identify regional hotspots in real time. Moreover, to further improve the robustness and generalizability of the models, we plan to expand and diversify our dataset to include more varied samples. This expansion will facilitate the implementation of more rigorous evaluation methods, such as cross-validation, which will help enhance the reliability and unbiased assessment of model performance.

Acknowledgments

The work was done with partial support from the Mexican Government through the grant A1-S-47854 of CONAHCYT, Mexico, and grants 20241816, 20241819, and 20240951 of the Secretaría de Investigación y Posgrado of the Instituto Politécnico Nacional, Mexico. The authors thank the CONAHCYT for the computing resources brought to them through the Plataforma de Aprendizaje Profundo para Tecnologías del Lenguaje of the Laboratorio de Supercómputo of the INAOE, Mexico, and acknowledge the support of Microsoft through the Microsoft Latin America PhD Award.

Abstract

Background: A high prevalence of dry eye disease (DED) has intensified public health concerns in Taiwan. With the growing reliance on online resources for health information, platforms such as Google Trends (GT) provide a valuable method for capturing public interest. This approach also allows for the exploration of potential associations between public interest in DED and environmental parameters, which may further elucidate underlying factors contributing to the disease's rising prevalence.

Objective: This study aims to (1) analyze public interest in DED in Taiwan using GT data, (2) investigate correlations between search interest and environmental parameters, and (3) identify shifts in the focus of search over time.

Methods: We analyzed GT data from December 2018 to July 2024, focusing on relative search volume (RSV) for DED across Taiwan and its 6 special municipalities. Temporal trends in RSV were assessed using spline regression models, and monthly variations were assessed using the Kruskal-Wallis test. The Spearman correlation analysis was used to evaluate the association between RSV and environmental parameters, while dynamic time warping analysis clarified the temporal alignment of RSV with these parameters. Rising search queries were analyzed to identify shifts in public interest over time. Furthermore, top Google search results for DED-related keywords were assessed for topic coverage, quality, and readability.

Results: A significant rising trend in RSV for DED was observed over the study period in Taiwan (mean instantaneous derivative=0.445; P<.001) and across all 6 special municipalities. Environmental parameters such as methane (CH_4), total hydrocarbons, and nonmethane hydrocarbons were identified as novel pollutants strongly correlated with RSV (P<.001), along with known pollutants such as nitric oxide (NO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), nitrogen oxides (NOx), and carbon monoxide (CO). Dynamic time warping analysis revealed the strongest temporal alignment was between RSV and hydrocarbons, including CH_4 and total hydrocarbons, further emphasizing their potential role in influencing public interest. Assessment of web-based DED information of 80 websites revealed generally low quality (DISCERN score: mean 2.14, SD 0.40), and the average readability corresponded to a college reading level (grade: mean 21.1, SD 4.5). Rising search queries shifted from diagnostic and treatment methods before the COVID-19 pandemic to natural remedies during the COVID-19 lockdown and self-diagnosis and treatment options after the pandemic. Gaps were also identified between public interest and the availability of online information.

Conclusions: Public interest in DED has increased significantly in Taiwan from 2018 to 2024, with hydrocarbons identified as strongly associated environmental parameters. The shifts in related queries reflect changing public interest, accentuating the need for health care information that aligns with public interest and addresses gaps in available resources.

Introduction

Background

Dry eye disease (DED) is a multifactorial ocular surface disease, with symptoms ranging from discomfort to significant visual impairment [1]. The prevalence of DED ranges from 5% to 50% globally and appeared to be higher in Asian populations than in White populations [2,3]. In a recent meta-analysis, the prevalence and incidence of DED in Asia were estimated to be 20.1% and 16.7%, respectively [4]. High prevalence of DED leads to substantial economic and human burdens, both worldwide and in Asia. In Taiwan, 33.7% of patients older than 65 years are estimated to have DED, and the incidence rates of DED increased at least 2-fold from 2001 to 2015, indicating the growing burden of the disease [5,6].

Despite the growing burden of DED, understanding the patterns of public awareness and information-seeking behavior is crucial for tracking the epidemiological pattern of a disease as well as improving patient education and care strategies [7]. With the rise of internet use, people increasingly rely on online resources for health information. Thus, infodemiology research allows researchers to track disease awareness and behavioral trends at a population level. By analyzing search patterns, we can capture the public's real-time interest, helping to identify gaps between public knowledge and clinical understanding [8]. Google Trends (GT), a tool that tracks real-time search queries, has emerged as a valuable platform for analyzing public interest in ocular or environmental health conditions [9-11].

Prior GT studies mapped DED interest across US regions and explored its seasonal variations in Saudi Arabia [10,12], while broader environmental-health work has linked spikes in searches for symptoms such as cough or asthma to particulate matter with diameter ≤2.5 μm ($PM_{2.5}$) and nitrogen dioxide (NO_2) levels [13-15]. To date, however, no study has examined how public interest in DED interacts with the full spectrum of local environmental factors, creating a research gap at the intersection of these fields.

Objectives

Therefore, we aim to explore the public interest in DED in Taiwan using GT data in this study. Specifically, we seek to analyze temporal and seasonal trends, investigate the correlation between search patterns and environmental parameters, and assess the rising search queries related to DED. Furthermore, we will evaluate whether the information provided by web-based resources aligns with public interests as reflected in the search data.

Methods

Data Collection: GT

Our data were sourced from GT [16], which provides relative search volume (RSV)—a metric that reflects the level of search interest relative to the total number of search queries within a specific time frame and geographic location. RSV values are normalized between 0 and 100, enabling straightforward comparisons of search interest over time.

A unique feature of GT is its use of "topics," which groups related searches across various languages and search term variations. For instance, a search for *dry eye* will return results under the *DED* topic, encompassing all searches linked to the condition, regardless of how users phrase their queries. In addition, the "rising queries" feature emphasizes search terms that have seen a substantial increase in volume over a specified time frame compared to the previous period, making it particularly useful for identifying emerging trends in public interest.

We initially identified global topics related to DED from 2004 onward, with 2 key topics emerging: *DED* and *dry eye*. Upon comparison, Taiwan exhibited the highest RSV for the *DED* topic worldwide, indicating a significant public interest in the condition within the region. Consequently, we focused our analysis on the *DED* topic for this study.

For the query analysis, we retrieved recent GT data spanning from December 2018 to July 2024. The COVID-19 lockdown period was defined based on Taiwan's nationwide level 3 alert, which lasted from May 19, 2021, to February 28, 2022, and involved strict restrictions on public movement and social gatherings. The post–COVID-19 period spanned from March 2022 to July 2024, corresponding to the end of our data collection. To ensure a balanced comparison, the pre–COVID-19 period was defined as December 2018 to April 2021, matching the duration of the post–COVID-19 period. In addition, we used the rising queries feature in GT to analyze public interest in DED across these periods. We extracted all the top rising queries reported by GT for each defined period (pre–COVID-19, COVID-19 lockdown, and post–COVID-19) to capture the most prominent emerging interests. The rising queries in each period were identified and compared to assess changes in public interest toward DED throughout the COVID-19 pandemic. Rising related queries were then categorized into 5 groups based on their theme: symptoms, treatment, etiology or related diseases, diagnosis, and others.

Data Collection: Environmental Parameters in Taiwan

We collected environmental and climate data from 6 special municipalities in Taiwan (Taipei City, New Taipei City, Taoyuan City, Taichung City, Tainan City, and Kaohsiung City) for the same period as the GT data (December 2018 to July 2024). The data were downloaded from the official websites of 2 primary agencies: the Central Weather Administration (CWA) of Taiwan and the Environmental Information Open Platform of Taiwan's Ministry of Environment. Our analysis examined important meteorological parameters, including average temperature, average relative humidity, evaporation, global solar radiation, precipitation, days with precipitation, average wind speed, and average wind direction, which may affect the severity of DED [17]. We also included established pollutants previously linked to DED, such as $PM_{2.5}$, NO_2, sulfur dioxide (SO_2), ozone (O_3), and carbon monoxide (CO) [18-21]. Furthermore, other routinely monitored major air pollutants from the CWA and Taiwan's Ministry of Environment, including hydrocarbons such as methane (CH_4), total hydrocarbons (THC), and nonmethane hydrocarbons (NMHC), were incorporated into our analysis. These hydrocarbons are

XSL•FO
RenderX

also recognized for their irritant properties, and previous studies suggested potential pathways for ocular surface impact, including direct and indirect injury to the corneal epithelium and conjunctiva [22,23]. The data collection process involved downloading monthly reports from the official websites of relevant agencies. Meteorological data were retrieved from the CWA. Atmospheric pollutant data were downloaded from the Environmental Information Open Platform of the Ministry of Environment of Taiwan. Monthly averages for each environmental parameter were aligned with the corresponding monthly RSV data for each city. A direct comparison was then made between environmental parameters and public search interest.

Falsification outcomes were commonly used to evaluate the likelihood of false-positive results in main study outcomes that might arise from unmeasured confounders or limitations in internal validity [24]. Public interest in glaucoma, a common ocular disease, was considered a falsification outcome in our GT analysis.

Ethical Considerations

Our study used publicly available and anonymized data from GT and official government environmental databases in Taiwan (CWA and the Environmental Information Open Platform). As the data sources contained no identifiable private information, this research protocol was reviewed by the institutional review board of Chang Gung Memorial Hospital, which waived the requirement for formal approval and informed consent.

Statistical Analysis

All statistical analyses were conducted using RStudio (version 4.3.0; R Foundation for Statistical Computing). $P<.05$ was considered statistically significant, and all primary *t* tests were 2-tailed. To evaluate temporal trends in RSV, we used spline regression models to capture potential nonlinear patterns over time. Specifically, a linear model was fitted with RSV as the response variable and a B-spline basis with 4 *df* of the numeric time variable as the predictor to flexibly model the trend. The first derivative of this fitted spline was computed at each monthly time point, representing the instantaneous rate of change in RSV per year. The mean instantaneous derivative (MID) was then calculated by averaging these instantaneous yearly rates and subsequently dividing by 12 to express the final rate as an average change in RSV units per month. A positive MID indicates an overall increasing trend in search interest, while a negative MID indicates a decreasing trend. A residual bootstrap (1000 iterations) provided 95% CIs and *P* values for MID. Monthly variations in RSV were examined using the Kruskal-Wallis test, and RSV data were grouped by month for Taiwan and its 6 special municipalities. The results were visualized using box plots to illustrate the distribution of RSV across different time frames.

The Spearman correlation was used to assess the association between RSV for DED and environmental parameters. Monthly GT RSV data were complete for the study period. Environmental data were averaged monthly. Before these analyses and the subsequent dynamic time warping (DTW), environmental data also underwent linear interpolation to address missing values, and both the RSV and environmental time series were standardized. Most monthly environmental data were complete across the 6 municipalities, except for Tainan. For Tainan, some climate parameters for September 2022 were missing and were imputed using linear interpolation. Additionally, the evaporation parameter was unavailable for Tainan and was thus excluded from the analyses for this municipality. The analysis was then conducted for each environmental parameter and RSV data across Taiwan and its 6 special municipalities, with significant correlations ($P<.05$) indicating a potential influence of the corresponding environmental parameters on public interest. No additional smoothing was applied to the monthly averaged environmental data series beyond the inherent effect of monthly averaging.

To more comprehensively account for potential nonlinear alignments or variable lags that might reflect delayed health impacts, DTW was used to evaluate the temporal alignment between RSV and multiple environmental parameters across 6 special municipalities in Taiwan. DTW is an algorithm that measures the similarity between 2 temporal sequences. It finds the optimal nonlinear alignment between the sequences, and the resulting DTW distance quantifies their dissimilarity.

To assess the alignment between topics of public interest and availability of public information, we searched Taiwan's Google website using Chinese keywords related to DED, including 乾眼 (dry eye), 眼睛乾澀 (dry eye discomfort), 乾眼症 (DED), 眼淚分泌減少 (decreased tear secretion), 淚液分泌不足 (insufficient tear secretion), 眼睛乾燥 (dryness of the eyes), and the terms 眼睛乾 and 眼乾 (collectively, ocular dryness). For each keyword, the top 20 search results were collected, resulting in an initial dataset comprising a total of 160 websites. Duplicate websites, including those with identical URLs or substantially overlapping content from the same author or organization, were identified and removed. The content of these remaining websites was reviewed and compared against the rising queries from GT. We examined which topics from the rising queries were covered in the sampled websites, how frequently they appeared, and which were absent. Furthermore, the quality and readability of these websites were assessed. Quality was evaluated independently by 2 ophthalmologists using the 16-item DISCERN instrument, with each item scored from 1 to 5 [25]. Discrepancies in DISCERN scores were resolved through discussion and consensus between 2 ophthalmologists. Readability was assessed using a web-based tool [26]. The frequency of each related term that appeared in both the websites and rising queries was recorded. The detailed methodology and key findings of the study, including public interest trend analysis, environmental associations, shifts in public search behavior, and the web-based information assessment, are summarized in Table S1 in Multimedia Appendix 1.

Results

Trends in RSV for DED From 2018 to 2024 in Taiwan and 6 Special Municipalities: Temporal and Monthly Variation

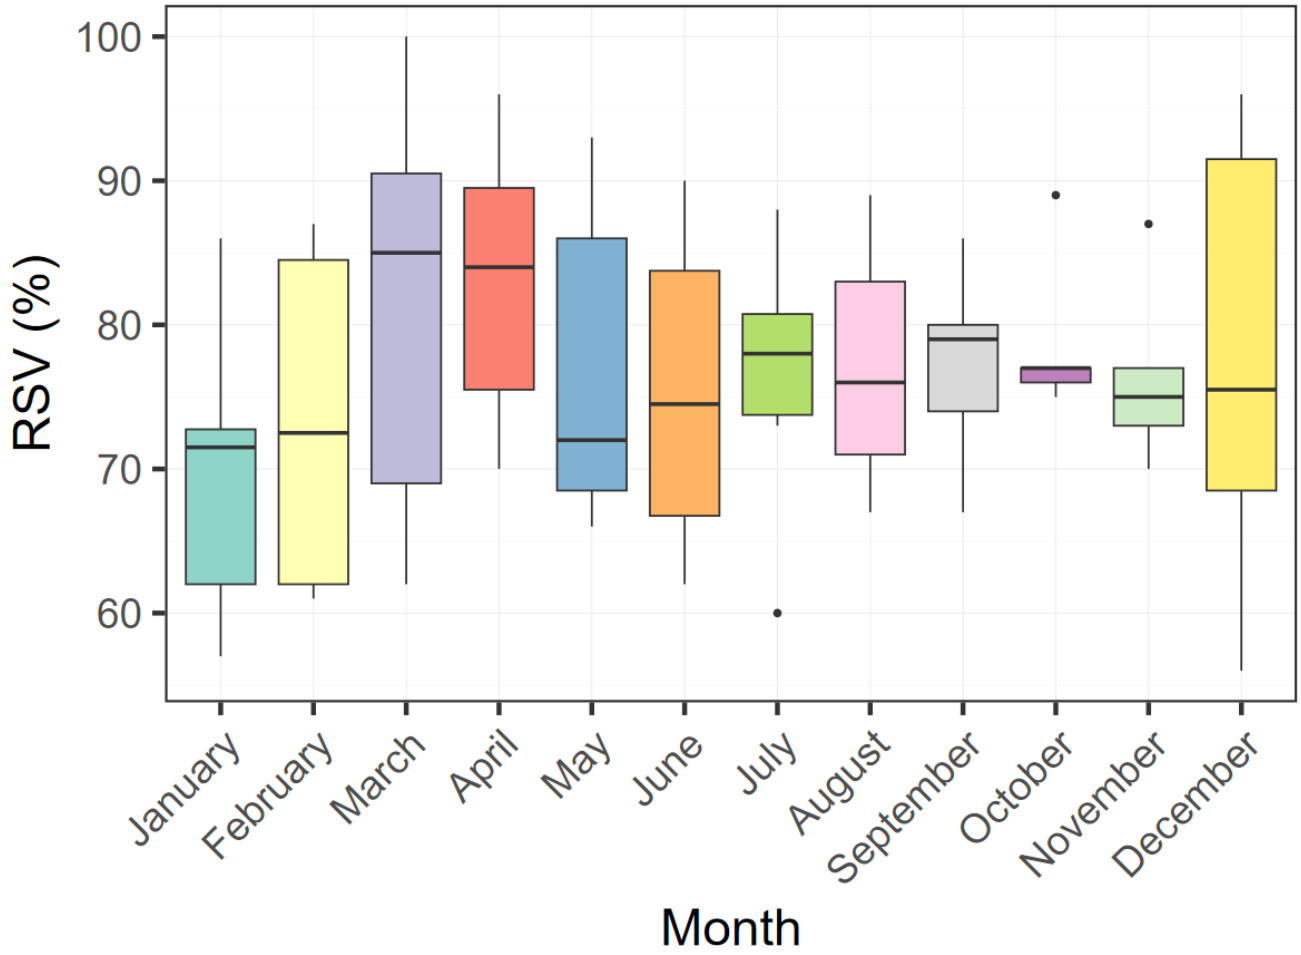

Figure 1 presents the trends in RSV for DED from December 2018 to July 2024 in Taiwan. The spline regression analysis for Taiwan showed an adjusted R^2 of 0.619 with P<.001, as detailed in Figure 1 and Table S2 in Multimedia Appendix 1. Spline regression models for each city demonstrated significant positive trends in RSV over time, which is illustrated in Figure S1 in Multimedia Appendix 1. A geospatial visualization of these regional trends is provided in Figure S2 in Multimedia Appendix 1. The adjusted R^2 values varied among cities, with Taipei City showing the highest (adjusted R^2=0.598; P<.001) and Taoyuan City the lowest (adjusted R^2=0.228; P<.001). Significant positive trends in RSV were also observed in most cities. As a falsification outcome, glaucoma demonstrated no statistically significant trend over the study period (MID=0.120; P=.12; Figure S3 in Multimedia Appendix 1). Analysis for Taiwan also revealed no significant monthly differences (Figure 2).

Figure 1. Trends in relative search volume (RSV) for dry eye disease in Taiwan from December 2018 to July 2024, based on Google Trends data. The blue line represents the overall RSV trend in Taiwan, with a mean instantaneous derivative computed at 0.445 per month (95% CI 0.308-0.593; P <.001), indicating a significant positive trend in public interest.

XSL•FO
RenderX

Figure 2. Monthly variations in relative search volume (RSV) for dry eye disease in Taiwan from December 2018 to July 2024. The Kruskal-Wallis test showed no statistically significant monthly differences in RSV (*P*=.85), suggesting consistent public search interest throughout the year.

Correlation Between RSV and Environmental Parameters

The results of the Spearman correlation analysis revealed significant associations between RSV for DED and multiple environmental parameters across Taiwan and its 6 special municipalities. In Taipei (Table 1), air pollutants such as CH_4, THC, SO_2, CO, NO, and NMHC demonstrated the strongest significant correlation with RSV (*P*<.001), followed by NO_2 , NOx, and average wind speed (*P*<.05). For other special municipalities across Taiwan, similar trends were also observed. CH_4, SO_2, and NMHC were significantly correlated to RSV in at least 5 of the 6 special municipalities (Table S3 in Multimedia Appendix 1). The results emphasized an association between air quality and public interest in DED. DTW analysis was used to further assess the temporal alignment between RSV and the environmental parameters identified as statistically significant in the Spearman correlation analysis. Across Taiwan's 6 special municipalities, the resulting DTW distances revealed that air pollutants were among the most strongly correlated parameters. Consistently, hydrocarbons such as CH_4 and THC, along with environmental parameters like ADT and AT, showed the smallest DTW distances, indicating the strongest temporal alignment with public search interest. A full list of DTW distances is available in Supplementary Table 4 in Multimedia Appendix 1.

[m]Significant correlation at $P<.001$.
[n]NMHC: nonmethane hydrocarbon.

Rising Queries From GT for DED in Taiwan

Rising search queries from GT across different periods showing shifting interests are summarized in Table 2. In the pre–COVID-19 period, the focus was primarily on diagnostic and treatment methods such as intense pulsed light (IPL) and Schirmer test. During the COVID-19 lockdown, there was increased interest in natural remedies, such as omega-3 fatty acids, natural eye drops, and lutein. In the post–COVID-19 period, there were more frequent searches for self-diagnosis

XSL•FO
RenderX

and treatment options such as dry eye self-diagnosis, forums, and sicca syndrome. The Chinese keywords that correspond to each English terms are listed in Table S5 in Multimedia Appendix 1.

The alignment between rising related queries from GT and accessible web-based information revealed a strong focus on DED symptoms, treatments, and self-care (Table S6 in Multimedia Appendix 1). The most frequently mentioned terms were *dry eye*, *dry eye symptoms*, and *dryness*, each appearing 80 times. Treatment-related queries were also prominent, such as *eye drops* (60 times), *artificial tears* (58 times), and *essential fatty acids* (34 times). Invasive treatments such as *IPL* (18 times) and *dry eye surgery* (22 times) were commonly mentioned. Other terms such as *contact lens* (53 times) and *Schirmer test* (23 times) were also popular. However, treatments such as *Chinese medicine* appeared only 5 times, and *cost of IPL* was not mentioned.

Before the COVID-19 pandemic, Taiwanese rising web searches about dry eye were split between understanding the condition (symptoms, causes, and prognosis) and new treatments such as IPL therapy and fish oil supplementation. During the COVID-19 lockdown, work-from-home screen fatigue and *mask-associated dry eye* likely increased discomfort, coinciding with reduced access to clinics [27,28]. Rising search behavior pivoted accordingly: people wanted some self-treated remedies, such as natural eye drops, vitamin A, omega-3, and fish oil. Once restrictions were eased, queries increasingly focused on documenting and professionalizing care. Terms such as self-tests, Schirmer values, *sicca syndrome ICD-10*, and *dry-eye treatment near me* indicate that patients were reengaging with ophthalmologists, insurance reimbursements, and telehealth workflows they had become familiar with during the pandemic. Together, the 3 phases trace a shift from curiosity, through pandemic-induced self-reliance, to post–COVID-19 integration of professional and community resources for chronic ocular surface disease.

Table . Top rising Google Trends queries for dry eye disease in Taiwan.

Period and ranking[a]	Queries	Rising
Pre–COVID-19 pandemic		
1	Intense pulsed light	Breakout[b]
2	Will dry eye disease get better	Breakout
3	Schirmer test	Breakout
4	Dry eye treatment	Breakout
5	Chalazion	Breakout
6	Omega-3	Breakout
7	Dry eye causes	110%
8	Dry eye symptoms	100%
9	What to eat for dry eye	90%
10	Will dry eye get better	70%
11	Fish oil	50%
COVID-19 pandemic		
1	Omega 3	Breakout
2	Natural eye drops	Breakout
3	Lutein	450%
4	Dry eye symptoms	170%
5	Intense pulsed light cost	170%
6	Dry eye improvement	110%
7	Conjunctivitis	80%
8	Vitamin A	80%
9	Fish oil	60%
10	Will dry eye get better	50%
Post–COVID-19 pandemic		
1	Dry eye self-diagnosis	Breakout
2	Dry eye forum	Breakout
3	Sicca syndrome ICD-10[c]	Breakout
4	Dry eye treatment near me	Breakout
5	Dry eye forum	250%
6	How long does dry eye take to get better	190%
7	Intense pulsed light	90%
8	What to eat for dry eye	60%

[a]The top rising rankings in the related queries for relative search volume during the respective periods are included.

[b]The ”breakout” label indicates a sharp increase in relative search volume, with popularity growing by >5000%.

[c]*ICD-10*: *International Classification of Diseases, Tenth Revision*.

Quality and Readability Assessment of Web-Based Information

After duplicate removal, 80 unique websites providing information on DED were evaluated (Table S7 in Multimedia Appendix 1). The mean DISCERN score of these websites was 2.14 (SD 0.40). Websites scored higher on clarity of aims (item 1: mean 3.79, SD 0.44), achieving aims (item 2: mean 3.26, SD 0.65), and relevance (item 3: mean 4.64, SD 0.64). However, significant weaknesses were observed in several critical areas, such as clarity on information sources (item 4: mean 1.24, SD 0.58), date of information production (item 5: mean 1.60, SD 0.63), provision of additional support details (item 7: mean 1.15, SD 0.42), and addressing areas of uncertainty (item 8: mean 1.09, SD 0.36). Furthermore, information regarding treatment choices was inadequate, with low scores for discussing risks of

XSL•FO
RenderX

treatment (item 11: mean 1.71, SD 0.51), what happens if no treatment is used (item 12: mean 1.05, SD 0.31), impact on quality of life (item 13: mean 1.11, SD 0.39), presenting multiple treatment choices (item 14: mean 1.96, SD 0.60), and supporting shared decision-making (item 15: mean 1.11, SD 0.39). The mean overall quality rating (item 16) was also low at 2.23 (SD 0.62). Readability, assessed using the specified web-based tool, had a mean score of 21.13 (SD 4.51), corresponding to a level above high school.

Discussion

Principal Findings

Current studies exploring public interest for DED using GT data are limited [10,29]. In our study, we observed trends in RSV for DED and examined correlations with environmental parameters. We also identified public concerns and gaps in available medical information from Google search regarding DED–related queries.

Although the topic presented in GT was *DED*, we used the term DED interchangeably to align with terminology commonly used in previous studies [30-32]. The term *DED* is retained when specifically referring to the GT topic under analysis to accurately reflect the platform's terminology. Our findings indicated that Taiwan has the highest RSV for DED globally according to GT data, which corresponded to the higher prevalence of DED in Taiwan compared to the worldwide average [33,34]. The rising RSV and higher prevalence for DED in Taiwan may be attributed to several factors, including increasing environmental pollution, the widespread use of digital devices, and cultural habits such as extensive air conditioner use [4,18,35,36]. The higher prevalence of DED in Taiwan compared to Western countries emphasized the impact of environmental and lifestyle differences between these regions [4,5,36]. For comparison, glaucoma in GT demonstrated no statistically significant trend, suggesting that the significant rise in DED-related RSV is less likely to result from unmeasured confounding factors and instead reflects a significant increase in public interest. This supports the robustness of the observed increase in RSV for DED.

Our study using the Kruskal-Wallis test found no significant monthly differences in RSV for DED in Taiwan. Previous research on seasonal variation in DED had mixed findings, with seasonal variations observed in high-altitude regions but not in low-altitude regions [18,37,38]. In high-altitude regions, the most severe DED symptoms, including discomfort, burning, and dryness, were observed, with the highest prevalence in spring and the lowest in summer [37,38]. One systematic review in China also revealed that the seasonal trend in DED was more evident in the northern regions than in the southern regions [39]. Taiwan's low latitude results in relatively mild seasonal temperature changes, and its consistently rainy weather maintains high humidity throughout the year. These factors may contribute to the lack of seasonal variation in DED [18] and could also indirectly influence RSV for DED.

Environmental factors play a crucial role in the development and exacerbation of DED in Taiwan [18]. Previous studies have identified pollutants such as PM_2 ., NO_2 , CO, SO_2 , and O_3 as contributing to ocular surface inflammation and DED symptoms [18-21]. For example, SO_2 and CO are associated with increased DED by potentially altering the structural composition of the outermost lipid layer of the precorneal tear film, leading to ocular discomfort and inflammation [40]. Concurrently, NO_2 is understood to disrupt the tear film lipid layer by altering the composition of O-acyl-ω-hydroxy fatty acids [41]. In our study, the Spearman correlation analysis revealed that higher concentrations of NO, NO_2 , SO_2, NOx, and CO were significantly associated with increased RSV, consistent with the pollutants identified in previous studies [18-21]. Moreover, in our study, we identified new air pollutants that may contribute to the occurrence of DED. These include CH_4, THC, and NMHC, all of which demonstrated a strong correlation with RSV (P<.001). The findings reveal a significant and previously unrecognized association between hydrocarbon levels and public interest in DED, suggesting their potential role as emerging environmental risk factors for the disease. Hydrocarbons, including CH_4, THC, and NMHC, are implicated in ocular surface pathology through several potential mechanisms. First, they contribute to the generation of potent secondary irritants, such as formaldehyde and acrolein, via photochemical reactions with NO in the atmosphere [42,43]. These aldehydes are known to damage the corneal epithelium and conjunctiva directly [17]. Second, the reactive aldehydes may destabilize the tear film lipid layer, thereby increasing tear evaporation and inducing hyperosmolarity, a key driver in DED pathogenesis [44]. Furthermore, some studies suggest that exposure to hydrocarbons may correlate with systemic inflammatory markers, which could amplify ocular surface immune responses [45]. The symptoms of DED might prompt patients to seek information online, consequently increasing RSV. Future investigation is needed to elucidate the specific biological mechanisms through which hydrocarbons may trigger or exacerbate DED symptoms.

To further clarify the temporal alignment between RSV and the environmental parameters significantly correlated in the Spearman correlation analysis, we used DTW analysis [46,47]. Our findings revealed that CH_4 and THC had the smallest DTW distances with RSV, indicating a strong temporal correlation. The strong correlation between RSV and hydrocarbons like CH_4 and THC suggests that these pollutants may significantly impact public interest in DED. These results, combined with the strong correlations observed in the Spearman correlation analysis, suggest that hydrocarbons may play a significant role in influencing public interest in DED. Hydrocarbons are emitted from various sources, including vehicles, industrial processes, and agricultural activities. Exposure to high levels of hydrocarbons may cause ocular irritation, tear film instability, and inflammation of the ocular surface, leading to potential DED symptoms [22,48]. This may prompt individuals to seek information online, contributing to our findings of increased RSV for DED.

Regarding public interest in DED, previous studies showed that public trends toward DED often involved treatment information and home remedies but lacked information about treatment risks and necessity [49]. A study by Yu et al [50] examined public trends toward DED based on the Baidu index, showing that

XSL•FO
RenderX

treatment options, subjective symptoms, and associated ocular diseases such as conjunctivitis and keratitis are the most popular terms related to DED. Similar to these findings, our study (Table S7 in Multimedia Appendix 1) also observed significant public interest in treatment options and subjective symptoms. However, our analysis further revealed unique trends in diagnostic queries and information-seeking behaviors, such as *Schirmer test* and *dry eye self-diagnosis*. Overall, our findings emphasize a growing public engagement with DED that extends beyond basic treatment information to include diagnosis, etiology, and symptoms.

Our analysis of rising search queries revealed a shift in public interest over time. During the COVID-19 pandemic, the trend likely reflected a shift toward self-care options and preventive health practices when access to traditional health care services was limited. In the post–COVID-19 period, the trend moved toward self-diagnosis and treatment options. This indicated increased health literacy and patient autonomy in health management [51,52].

Our analysis of rising Google search queries and RSV revealed significant public interest in specific aspects of DED, with notable shifts over time (Tables S5 and S6 in Multimedia Appendix 1). For instance, while topics such as *Chinese medicine* and *cost of IPL* emerged as rising queries, they were lacking in available web-based resources. Furthermore, when we compared these demonstrated public interests, we identified a clear gap between public interests and the availability of corresponding online medical information. Beyond the gaps in topic coverage, our DISCERN analysis (Table S7 in Multimedia Appendix 1) further highlights the nature of the quality deficiencies. While the evaluated websites generally presented clear aims and relevant content (DISCERN items 1‐3), they demonstrated crucial deficiencies in several areas of reliability, such as poor transparency of sources (item 4) and outdated information (item 5). Moreover, the information provided on treatment choices was notably lacking, particularly in outlining risks (item 11) and facilitating shared decision-making (item 15), culminating in a low overall quality score (item 16). These specific shortcomings, combined with the high readability level, suggest that much of the online DED information in Taiwan may not only be difficult to understand but also lacks the balance and comprehensive details necessary for informed health decisions. These findings collectively accentuate the need for health care providers and public health organizations to address these identified gaps. Public health organizations should promote clear digital guidance on DED self-care, natural remedies, and IPL. Clinicians and health care providers should then use this guidance in patient consultations to address self-treatment trends, clearly articulate potential risks, and guide patients toward professional intervention, ensuring cost implications are also discussed. A key strategy for all involved is to proactively engage in digital health communication by developing and disseminating accessible, evidence-based content through their websites and social media.

Limitations

Our study has several limitations. First, RSV data from GT reflect search interest rather than confirmed DED prevalence or specific unmet health needs. Search behavior can be influenced by factors unrelated to disease incidence, such as media coverage, public health campaigns, seasonality, or emerging news events, which were not controlled for in this analysis [51,52]. Consequently, an observed increase in search interest does not necessarily equate to a parallel rise in DED prevalence or severity. Although our falsification outcome (glaucoma) showed no upward trend, the aforementioned residual confounding factors cannot be excluded. Second, the analysis is limited to Taiwan, so the findings may not be generalizable to other regions, and other unmeasured factors may also influence DED symptoms and public interest. Third, the general increase in internet penetration and use over time could contribute to the overall rising trend in RSV, although the use of a falsification outcome (glaucoma) showing no significant trend lends support to the specificity of the DED finding. Moreover, the lack of direct mechanistic studies on the role of hydrocarbons in DED represents a main limitation of our study. Further research should explore the mechanisms by which hydrocarbons influence the ocular surface and contribute to DED pathogenesis.

Conclusions

This study provides a comprehensive analysis of GT data, demonstrating a significant increase in public interest in DED in Taiwan from December 2018 to July 2024. Novel air pollutants, particularly hydrocarbons such as CH_4, THC, and NMHC, were identified as key factors strongly associated with public interest in DED. Our findings also emphasize the necessity for health education to bridge the gap between public interest and available public information.

Acknowledgments

The authors acknowledge the use of the generative artificial intelligence tool ChatGPT (OpenAI) during the preparation of this manuscript. The tool was used for the purpose of refining grammar and improving sentence clarity in the manuscript writing process. After using the tool, all AI-assisted text was critically reviewed, revised, and edited by the human authors, who take full responsibility for the final content's accuracy and integrity.

Data Availability

The data that support the findings of this study are openly available from public domains. Google Trends data are available from the platform itself [16]. Environmental data are available from the Central Weather Administration of Taiwan and the Environmental Information Open Platform of Taiwan's Ministry of Environment. The specific datasets generated and analyzed during the current study are available from the corresponding author on reasonable request.

Abstract

Background: Hand, foot, and mouth disease (HFMD) is a global health concern requiring a risk assessment framework based on systematic factors analysis for prevention and control.

Objective: This study aims to construct a comprehensive HFMD risk assessment framework by integrating multisource data, including historical incidence information, environmental parameters, and web-based search behavior data, to improve predictive performance.

Methods: We integrated multisource data (HFMD cases, meteorology, air pollution, Baidu Index, and public health measures) from Bao'an District of Shenzhen city in Southern China (2014 - 2023). Correlation analysis was used to assess the associations between HFMD incidence and systematic factors. The impacts of environmental factors were analyzed using the Distributed Lag Nonlinear Model. Seasonal Autoregressive Integrated Moving Average model and advanced machine learning methods were used to predict HFMD 1-4 weeks ahead. Risk levels for the 1- to 4-week-ahead forecasts were determined by comparing the predicted weekly incidence against predefined thresholds.

Results: From 2014 to 2023, Bao'an District reported a total of 118,826 cases of HFMD. Environmental and search behavior factors (excluding sulfur dioxide) were significantly associated with HFMD incidence in nonlinear patterns. For 1-week-ahead prediction, Seasonal Autoregressive Integrated Moving Average using case data alone performed best (R^2=0.95, r=0.98, mean absolute error=53.34, and root-mean-square error=99.31). For 2- to 4-week-ahead forecasting, machine learning models incorporating web-based and environmental data showed superior performance (R^2=0.83, 0.75, and 0.64; r=0.92, 0.87, and 0.80; mean absolute error=87.84, 112.41, and 132.47; and root-mean-square error=185.08, 229.13, and 276.81). The predicted HFMD risk levels matched the observed levels with accuracies of 96%, 87%, 88%, and 83%, respectively.

Conclusions: The epidemic dynamics of HFMD are influenced by multiple factors in a nonlinear manner. Integrating multisource data, particularly web-based search behavior, significantly enhances the accuracy of short- and midterm forecasts and risk assessment. This approach offers practical insights for developing digital surveillance and early warning systems in public health.

Introduction

Hand, foot, and mouth disease (HFMD), an infectious disease primarily affecting children younger than 5 years, has emerged as an important global public health challenge [1,2]. Driven mainly by enterovirus 71 (EV71) and coxsackievirus A16 (CA16), HFMD is easily spread in environments where children congregate [3]. It's typically 3 - 5 days of incubation that precedes distinctive rashes and vesicles on the hands, feet, and oral cavity [4]. The Asia-Pacific region bears a high burden [5], with China reporting a record of 1.68 million cases in 2023 [6]. For timely and targeted interventions, understanding the circulation mechanisms of HFMD and an accurate prediction model for real future risk assessment are needed.

The epidemiology of HFMD is shaped by a complex interplay of systematic factors. Beyond pathogen and host immunity impacts, meteorological conditions and air quality emerge as critical determinants of HFMD transmission dynamics [7]. A growing body of evidence highlights the significant influence of temperature, relative humidity, wind speed, and diurnal temperature range (DTR) on HFMD transmission [8-12]. In addition, air pollution has emerged as a crucial cofactor, with $PM_{2.5}$, PM_{10}, SO_2, NO_2, and O_3 levels demonstrating significant associations with HFMD incidence [9,10,13,14]. These environmental factors likely influence HFMD transmission through multiple pathways: altering viral viability, modulating host immunity, and affecting human behavior patterns [15,16]. Consequently, when constructing a risk assessment framework for HFMD, meteorological factors and air pollution should be considered as essential components.

While environmental drivers are well documented, traditional surveillance systems (eg, case reports) struggle to capture real-time transmission dynamics of HFMD. Web-based search data are a novel tool that can provide real-time insights via public queries on symptoms, treatments, and prevention [17,18]. Numerous studies demonstrate web-based search data's use in enhancing disease incidence prediction. Incorporating Baidu search index improves HFMD model accuracy [19], while Google Influenza Trends successfully tracked influenza outbreaks [20]. Similar applications in dengue, scarlet fever, chickenpox, and Ebola outbreaks [21-23] further validate this approach. However, challenges remain, including media-driven search distortion, inconsistent web-based penetration affecting data representativeness, and policy-induced shifts in search patterns [24]. Therefore, an optimal HFMD risk assessment framework should integrate traditional surveillance and web-based search data synergistically, balancing their complementary strengths for enhanced accuracy and timeliness.

Advancements in predictive modeling now offer opportunities to leverage these multisource data more effectively. Early studies predominantly used Seasonal Autoregressive Integrated Moving Average (SARIMA) time series models, which effectively capture annual cyclical and seasonal variations but require high data stationarity and struggle with nonlinear relationships and outliers [25-27]. Machine learning introduced advanced algorithms (eg, Extreme Gradient Boosting [XGBoost] and random forest [RF]), outperforming traditional models in capturing complex epidemiological patterns [28,29]. Hybrid models have further enhanced accuracy, such as ARIMA-EEMD-LSTM, combining time series decomposition with neural network adaptability [30-33]. However, current studies lack systematic comparisons between traditional and advanced models' predictive performance, as well as clear risk-level translation—both critical for accurate HFMD early warning.

Beyond model performance, the ultimate goal of ensuring the effectiveness of an HFMD risk assessment framework depends on its capacity to translate case predictions into actionable risk levels for prevention. Several Chinese cities have developed an influenza index and HFMD index [34-39]. For example, Shenzhen Center for Disease Control and Prevention implemented an HFMD risk index to guide targeted prevention measures based on risk levels [36,37], advising improved hygiene and avoidance of crowded areas during high-risk periods. However, current HFMD risk assessments often depend on single-source surveillance data for short-term (1-week ahead) predictions, limiting accuracy. Although some studies have developed multisource prediction models, effectively translating forecasts into actionable risk levels remains rare. This gap highlights the need for a more comprehensive risk assessment framework integrating multisource data for early warning and effective prevention.

This study is conducted in Bao'an District of Shenzhen, a typical high-density subtropical urban region within the Guangdong-Hong Kong-Macao Greater Bay Area that experiences persistent challenges in HFMD transmission. Despite the high disease burden, prediction research integrating environmental drivers with epidemiological patterns has remained limited. To address this gap, this study aims to develop a comprehensive HFMD risk assessment framework by integrating multisource data (historical incidence, environmental parameters, and web-based search behavior data), enabling the translation of predicted cases into actionable risk levels to support prevention strategies (Figure S1 in Multimedia Appendix 1).

Methods

Study Site

Bao'an District, located on the eastern bank of the Pearl River Estuary in the northwest of Shenzhen, a coastal region in South China, spans a total area of 724.6 square kilometers. The district's permanent resident population reached 4.5654 million in 2023, ranking first in the city. Characterized by a subtropical monsoon maritime climate, Bao'an District enjoys ample sunlight, abundant rainfall, and a mild climate. Specifically, the region has an average annual temperature of 22 °C, an average relative humidity of 76%, and an air quality excellence rate exceeding 90%. Regarding environmental air quality, particulate matter and ozone are the primary pollutants.

Data Sources

Incidence Data

The first dataset of this study comprises the case count of HFMD. We collected case data for Bao'an District, Shenzhen, from January 1, 2014, to December 31, 2023, through the "China Information System for Disease Control and Prevention." HFMD is classified as a Category C notifiable infectious disease, with case reporting adhering to the regulations of the "Law of the People's Republic of China on the Prevention and Treatment of Infectious Diseases" and the "Norms for the Management of Infectious Disease Information Reporting." The diagnostic criteria adhered to the Health Industry Standards of the People's Republic of China (WS 588 - 2018) [40]. The collected information documented the patient's gender, date of birth, and date of symptom onset. In this study, the daily number of HFMD cases was calculated based on the date of symptom onset.

Environment Data

Meteorological data were collected from an online platform that provides global weather information, encompassing daily average temperature, maximum temperature, minimum temperature, relative humidity, wind speed, and atmospheric pressure in Shenzhen. In addition, the DTR was calculated as the difference between daily maximum and minimum temperatures. Air pollution data were obtained from the Qingyue Data website, which includes daily average concentrations of fine particulate matter ($PM_{2.5}$, μg/m^3), inhalable particulate matter (PM_{10}, μg/m^3), sulfur dioxide (SO_2, μg/m^3), nitrogen dioxide (NO_2, μg/m^3), carbon monoxide (CO, mg/m^3), and ozone (O_3, μg/m^3) in Shenzhen.

Baidu Index

In this study, we collected daily HFMD-related keywords (n=51) from a commercial website and Baidu Index and supplemented them with additional terms (n=5) based on prior literature and etiological knowledge [41]. After excluding duplicates (n=2) and terms with a correlation coefficient less than 0.4 with HFMD (n=33), a total of 22 terms remained. These terms were categorized into 4 groups: definition (n=6), symptom (n=6), treatment (n=7), and prevention (n=2) (Table S1 in Multimedia Appendix 2). To construct 4 separate composite Baidu Indexes corresponding to each category, we calculated the product of each term's search frequency and its correlation coefficient with HFMD, normalized this product by the total correlation coefficient to obtain a ratio, and then summed these ratios within each category. These composite indexes were used to analyze and predict HFMD incidence trends.

$$(1) CI=\sum(Ni\times ri)/\sum ri$$

In equation (1), CI denotes the composite index, a metric designed to quantify the relationship between search trends of specific Baidu Index–related keywords and HFMD case numbers. N_i represents the search index for the i th keyword, reflecting the search volume of that HFMD-related keyword. r_i is Pearson correlation coefficient between the search index of the i th keyword and HFMD case numbers. ∑ri denotes the sum of Pearson correlation coefficients for all related keywords, serving as a normalizing factor to account for the collective impact of all selected keywords in the composite index.

Public Health and Social Measures

The Government Response Indicator was obtained from the COVID-19 Government Response Tracker . This composite index, based on 13 policy response indicators such as school closures, workplace closures, travel bans, testing policies, contact tracing, mask mandates, and vaccination policies, is standardized on a scale of 0-100, reliably measuring the intensity of public health and social measures (PHSMs) over time.

Statistical Analysis

Descriptive Analysis

Descriptive statistics were used to characterize HFMD case distributions across population, temporal, and spatial dimensions, and to assess the distribution of environmental factors and PHSMs. Spearman correlation analysis was used to evaluate the associations between HFMD case counts and both environmental factors and PHSMs. In addition, Pearson correlation coefficient was used to assess the correlation between the Baidu Index and the number of HFMD cases.

We used the Partial Autocorrelation Function (PACF) to analyze the autocorrelation between HFMD incidence and its lagged values. The PACF measures the direct correlation between the current value y_t and the lagged value y_{t-k}, after removing the effects of intermediate lags ($y_{t-1}, y_{t-2},..., y_{t-k-1}$) [42]. This analysis helped identify significant lagged correlations in the HFMD incidence time series, which informed model selection and parameter estimation.

We conducted lagged cross-correlation analysis to assess the relationship between Baidu Index and HFMD incidence at various time lags. This method evaluates the correlation between 2 time series while considering the dynamic interactions over time [43]. By calculating cross-correlation coefficients at different lags, we identified potential time-lagged associations between web-based search data and HFMD incidence. These findings provided essential time series feature information for constructing predictive models.

Factor Analysis

This study used the Distributed Lag Nonlinear Model (DLNM) to analyze the risk factors influencing HFMD. DLNM, which focuses on cross-basis functions, is capable of examining nonlinear and lagged effects between exposure and response variables. It has been widely used to study the complex impacts of environmental exposures on diseases [44]. By integrating the results of Spearman correlation analysis and excluding collinearity among environmental indicators, we ultimately selected environmental factors associated with HFMD for inclusion in the model. Environmental factors were treated as independent variables, with weekly case counts as the dependent variable, while controlling for confounding factors such as day-of-week effects, holiday effects, and long-term trends. Allowing for overdispersion, a quasi-Poisson regression was applied based on DLNM. The model formula is as follows:

$$(2) Yt\sim Quasi-Poisson(\mu t)$$

XSL•FO
RenderX

(3) $\log[\mu_t] = \alpha + cb(var) + ns(time_t, df = 7/year) + \beta Dow_t + Holiday_t + f(cov) + autoregressive\ terms$

In equations (2) and (3), Y_t represents the number of HFMD cases in week t; α represents the intercept; and var refers to meteorological factors or air pollutants. The function cb stands for cross-basis that integrates both exposure and lag dimensions. Dow_t represents the day-of-week effect, and $Holiday_t$ represents the holiday effect. ns indicates natural spline functions, and $time_t$ controls for long-term trends. The function f (cov) refers to other factors except var in the model to control the confounding effect. Autoregressive terms refer to the autoregressive terms of daily HFMD counts [45]. We used a smoothing function to manage the first and second lags of the number of cases in our model, indirectly reflecting the effect of population immunity on the pattern of HFMD transmission. The maximum lag days and degrees of freedom in the model were determined using the Akaike information criterion for quasi-Poisson (Q-AIC). The maximum lag time for environmental factors was set to 14 days, and the long-term trend was set to 7 per year. In this model, both environment factors and lag spaces were fitted using natural cubic spline functions, with 4 degrees of freedom (*df*) for environment factors and 3 *df* for lag spaces, based on the Q-AIC and prior literature [10].

Prediction Model

The prediction task was formulated as a retrospective time series regression problem, with the target being the weekly number of HFMD cases in the subsequent 1-4 weeks (Figure S1 in Multimedia Appendix 3). Given that previous studies have demonstrated the high accuracy of the SARIMA model in short-term forecasting of HFMD, we first constructed a prediction model using only HFMD case counts, based on the SARIMA model (Table S1 in Multimedia Appendix 4).

We then developed 1- to 4-week-ahead predictive models using 3 tree-based machine learning algorithms: RF, XGBoost, and Light Gradient Boosting Machine (LightGBM). Predictor variables included environmental factors associated with HFMD identified in previous analyses, Baidu Composite Index, PHSMs, holidays, week numbers, and historical HFMD case counts reflecting infection sources and population immunity (Table S1 in Multimedia Appendix 4). To address multicollinearity, variables with pairwise correlation coefficients exceeding 0.8 were screened, and those less correlated with HFMD incidence were excluded.

To further enhance prediction performance, we used a stacking ensemble strategy. The 3 tree-based models served as base learners, and their prediction outputs were used as input features for a metalearner. To reduce the risk of overfitting, we selected a linear regression model as the metalearner due to its simplicity and strong generalization ability. The final ensemble model was trained using this 2-level architecture.

Data from 2014 to 2023 were divided into a training set (2014 - 2022) and a testing set (2023). Model hyperparameters were tuned using 5-fold time series cross-validation on the training set. Based on the optimized parameters, we constructed 1- to 4-week-ahead predictive models for HFMD incidence using each of the 3 base models (RF, XGBoost, and LightGBM) as well as the stacking ensemble model.

Model performance was evaluated on the testing set using several common regression metrics, including the coefficient of determination (R^2), Pearson correlation coefficient (r), mean absolute error (MAE), and root-mean-square error (RMSE). Lower MAE, lower RMSE, higher R^2, and higher r indicated better forecasting performance (Formula 1 in Multimedia Appendix 5).

Risk Assessment

Based on the weekly HFMD case data from 2014 to 2019 (before COVID-19 pandemic), the cumulative distribution function of weekly case counts was calculated. The 40th, 60th, and 80th percentiles of the cumulative distribution function were then used as thresholds to classify epidemic risk levels. The selection of the 40%, 60%, and 80% quantiles as risk thresholds was based on 2 considerations. First, local experts recommended quantile-based thresholds for their practicality in supporting tiered risk management. Second, similar percentile-based classifications have been adopted in previous studies [34,39], which informed our framework design. Specifically, the predicted weekly case counts were compared against the aforementioned thresholds to determine the risk level as follows. High risk: case count >80th percentile; moderate risk: 60th percentile < case count ≤ 80th percentile; medium risk: 40th percentile < case count ≤ 60th percentile; and low risk: case count ≤ 40th percentile.

The accuracy of risk assessment was evaluated by calculating the accuracy rate, overestimation rate, and underestimation rate (Formula 2 in Multimedia Appendix 6). Higher accuracy and lower overestimation and underestimation rates indicated better risk assessment performance.

Software and Visualization

Data cleaning and descriptive analysis, as well as predictive analysis, were performed using Python (version 3.12.4; Python Software Foundation). Predictive models included SARIMA (pmdarima), machine learning algorithms such as RF (sklearn), extreme gradient boosting (xgboost), light gradient boosting (lightgbm), and a stacked model constructed using sklearn components. The DLNM was constructed in R (version 4.4.2; R Foundation for Statistical Computing) using the dlnm package.

Ethical Considerations

All data used in our study was anonymized and deidentified and did not involve data related to humans. Therefore, our research was exempted from the requirement of written informed consent and was approved by the ethics committee of the Bao'an Center for Disease Control and Prevention.

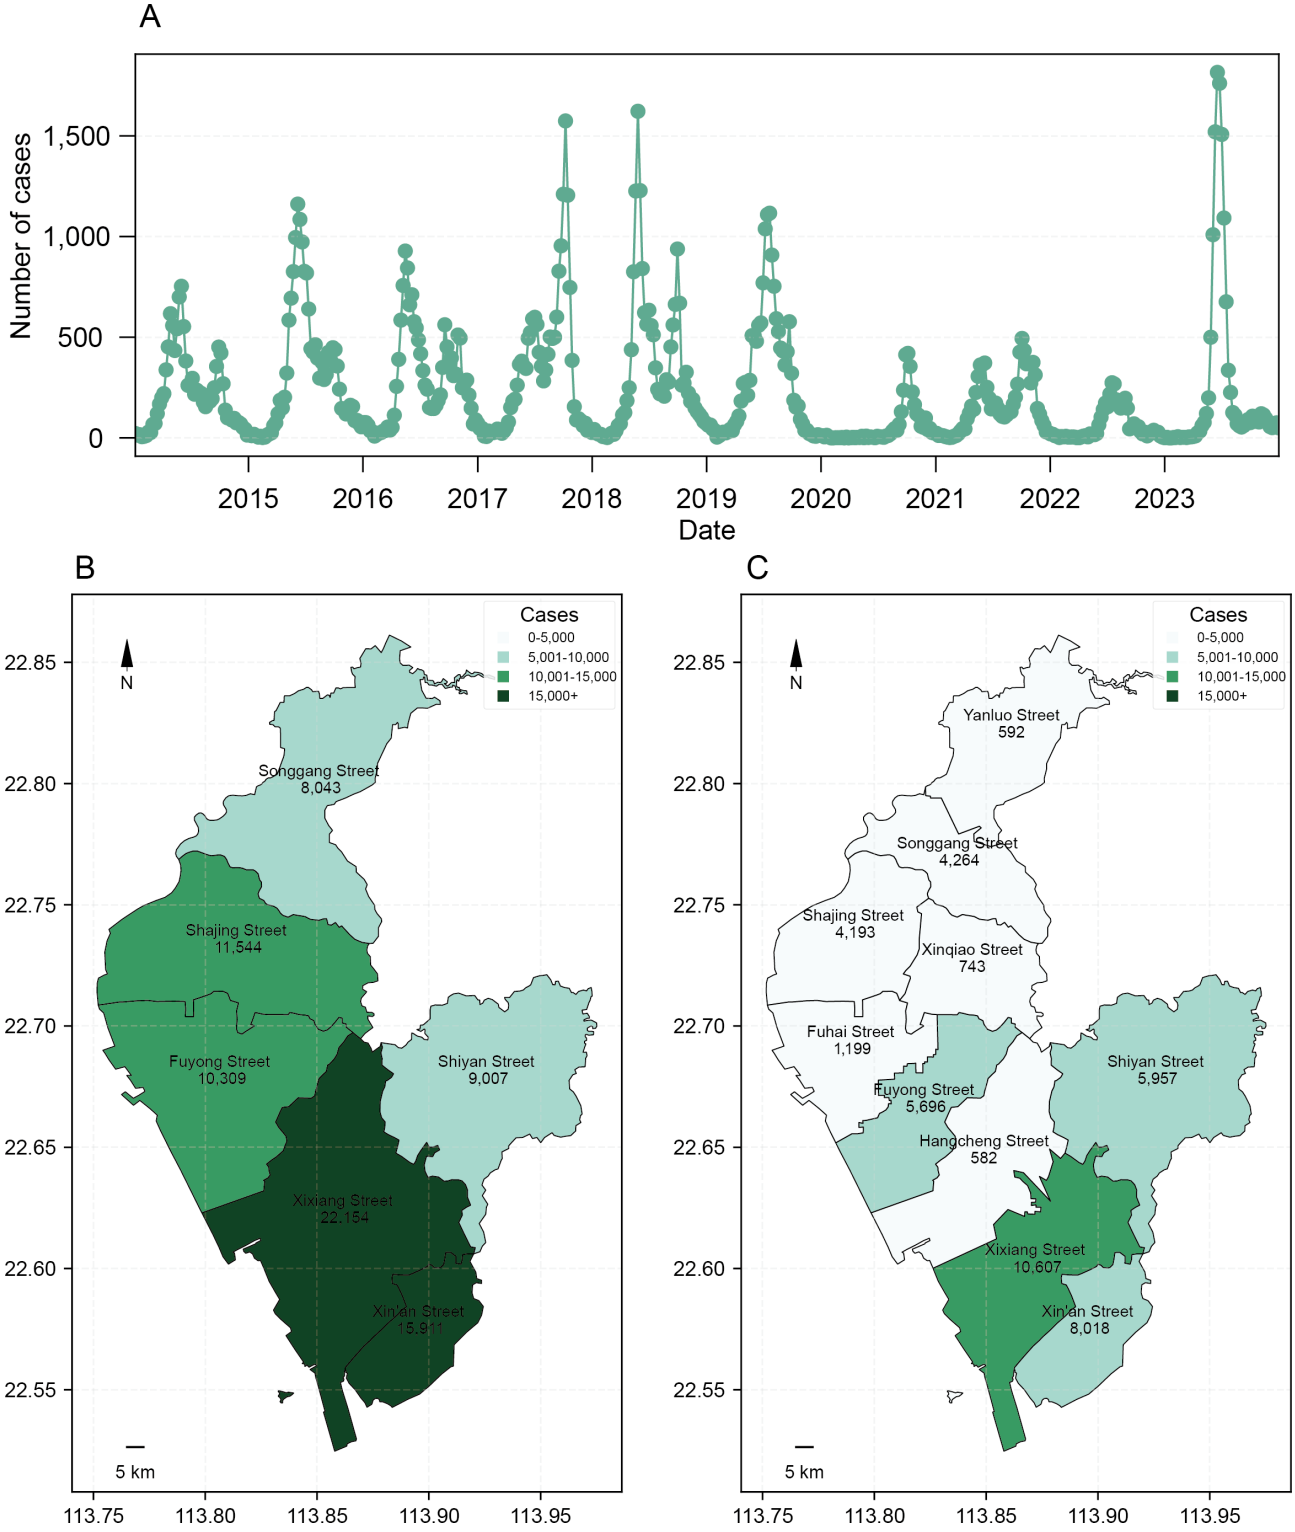
Results

Data Description

From 2014 to 2023, Bao'an District in Shenzhen City reported a total of 118,826 HFMD cases, 93.6% (111,181/118,826) of which occurred in children aged 5 years and younger (Table 1). The incidence of HFMD displayed a significant seasonal pattern

XSL•FO
RenderX

characterized by a bimodal distribution (Figure 1A). The primary peak spanned from approximately week 12 to week 32, coinciding with the spring and summer seasons, while a secondary peak emerged from around week 36 to week 45, corresponding to the autumn and winter seasons (Figure 1A).



During the study period, the incidence of HFMD in Bao'an District exhibited significant geographical variations. The highest incidence was observed in the central areas, specifically in Xin'an and Xi'xiang subdistricts (Figure 1B and C).

Table . Characteristics of the hand, foot, and mouth disease cases in Bao'an district of Shenzhen from 2014 to 2023.

Characteristics	Proportion, n (%)
Sex	
Male	71,441 (60.1)
Female	47,385 (39.9)
Age (years)	
0 - 5	111,181 (93.6)
6 - 12	6455 (5.4)
13 - 15	147 (0.1)
16 - 18	65 (0.1)
19 - 60	972 (0.8)
>60	6 (0.0)
Career	
Children in the diaspora	88,858 (74.8)
Children in nursery	24,809 (20.9)
Students	4169 (3.5)
Others	990 (0.8)

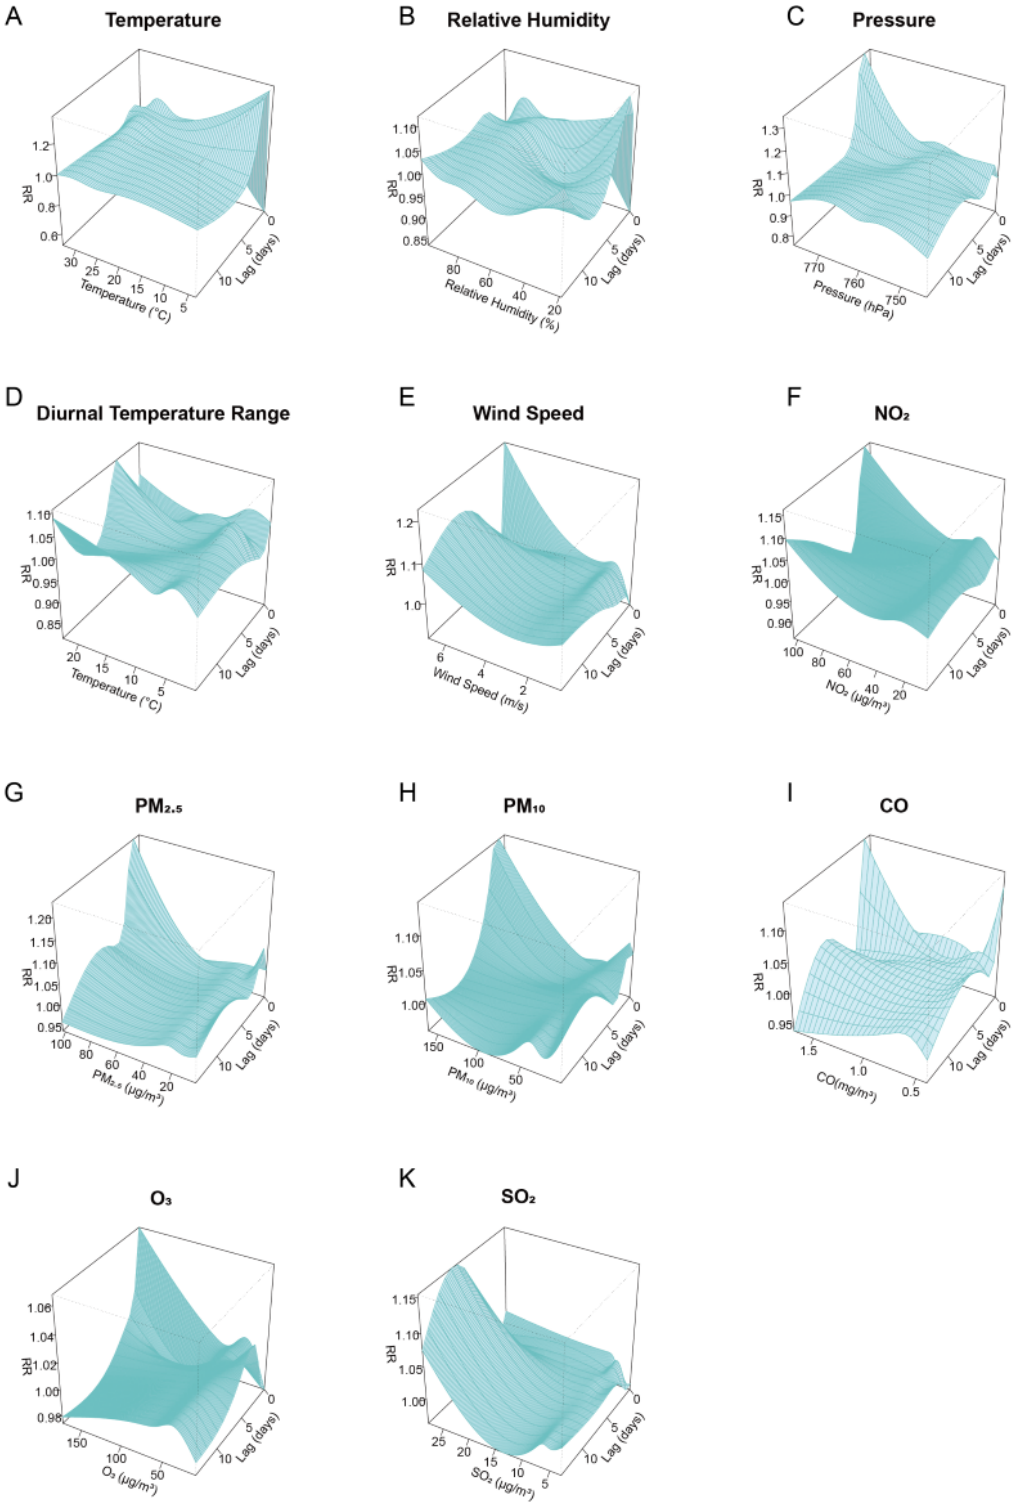
Figure 1. Temporal and spatial distribution of incidence of hand, foot, and mouth disease (HFMD) in Bao'an District from 2014 to 2023. (A) Time series diagram of the number of weekly HFMD cases. (B) Spatial distribution of the number of HFMD cases in Bao'an District from 2014 to 2018. (C) Spatial distribution of the number of HFMD cases in Bao'an District from 2019 to 2023.

Throughout the study period, meteorological factors such as temperature, atmospheric pressure, relative humidity, DTR, and air pollutants such as $PM_{2.5}$, PM_{10}, SO_2, NO_2, O_3, and CO, as well as Baidu Index showed obvious seasonal fluctuations (Figure S1 in Multimedia Appendix 7 and Figure S1 in Multimedia Appendix 8).

Systematic Factors Affecting HFMD

Table S1 in Multimedia Appendix 9 provides an overview of the statistical distribution of HFMD case counts and systematic factors. During the study period, the average number of HFMD cases was 32.53. Spearman correlation analysis between HFMD and environmental factors (Table S1 in Multimedia Appendix 9) revealed that daily average temperature exhibited the most significant correlation with HFMD, with a correlation coefficient

XSL•FO
RenderX



of 0.62. Except for SO_2, HFMD showed negative correlations with other air pollutants.

PACF analysis (Figure S1 in Multimedia Appendix 10) revealed significant autocorrelation between HFMD incidence and its lagged values at 1- to 3-week intervals. Lagged cross-correlation analysis (Figure S1 in Multimedia Appendix 11) indicated that Baidu search index, including both the composite index and the sub-index for definition, symptoms, treatment, and prevention, exhibited the strongest correlation with HFMD case counts during the week of disease onset.

The analysis of influencing factors indicates that meteorological variables and air pollutants exhibit lagged and nonlinear effects on HFMD incidence (Figure 2 and Figure S1 in Multimedia Appendix 12). Temperature demonstrates an inverted V-shaped relationship with relative risk increasing up to a specific threshold before declining (Figure 2A). Low relative humidity appears to have a protective effect, whereas low atmospheric pressure and a reduced DTR are associated with an elevated risk of HFMD (Figure 2B-D). Wind speed follows an S-shaped pattern in its association with HFMD incidence (Figure 2E). In our analysis, ambient concentrations of $PM_{2.5}$, PM_{10}, CO, and O_3 were inversely associated with HFMD risk (Figure 2G-J), with higher pollutant levels correlating with a lower relative risk of disease. Furthermore, NO_2 demonstrated a positive association with HFMD incidence at low concentration ranges (Figure 2F), while its effect was not statistically significant at higher or extremely low concentrations. In addition, SO_2 does not show a statistically significant impact on HFMD incidence and was therefore excluded from subsequent predictive modeling (Figure 2K).

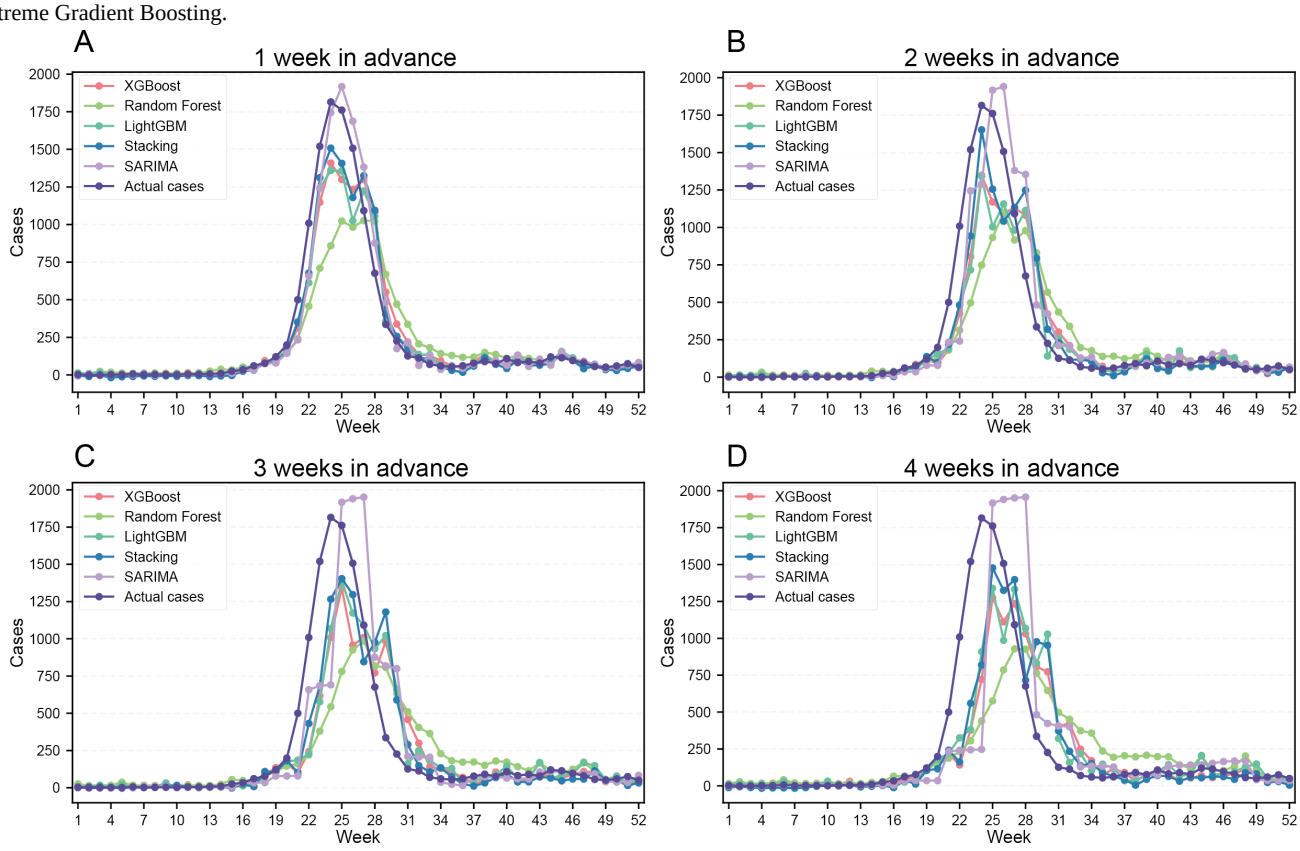
Figure 2. Relative risks for hand, foot, and mouth disease incidence associated with environmental factors and lags using Distributed Lag Nonlinear Models in Bao'an District from 2014 to 2023: (A) temperature, (B) relative humidity, (C) air pressure, (D) daily temperature range, (E) wind speed, (F) NO_2, (G) $PM_{2.5}$, (H) PM_{10}, (I) CO, (J) O_3, and (K) SO_2.

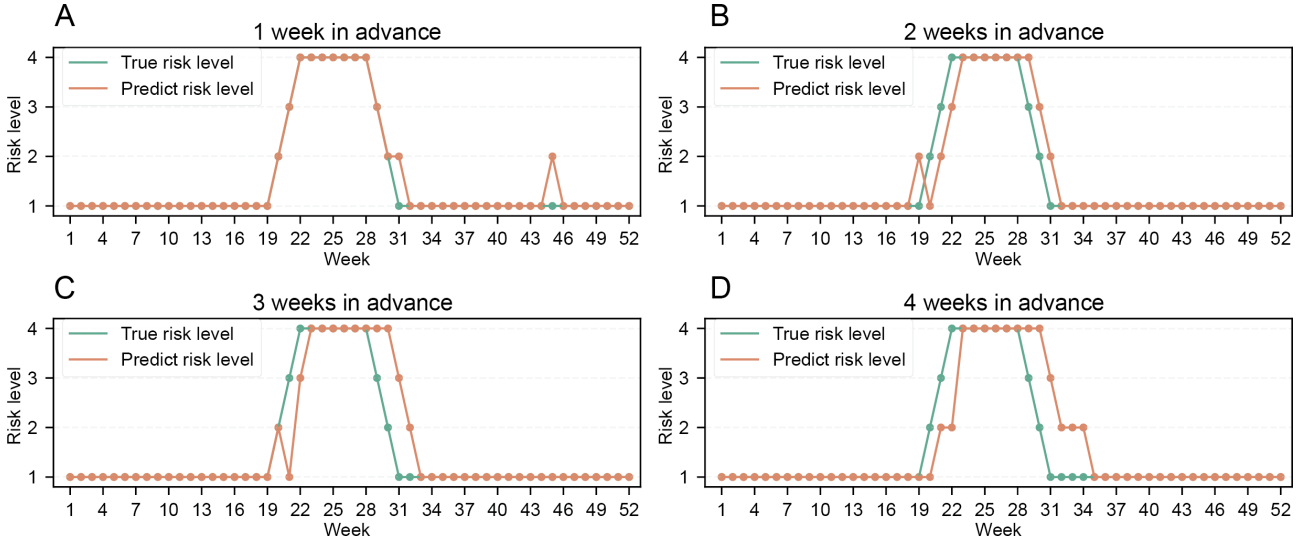


Predictive Results

The prediction results indicate that the SARIMA model exhibited the highest predictive accuracy for the 1-week-ahead forecast (R^2=0.95, r=0.98, MAE=53.34, and RMSE=99.31) (Table S1 in Multimedia Appendix 13 and Figure 3A). For midterm forecasts (2 - 4 weeks ahead), the ensemble model integrating multiple machine learning algorithms demonstrated superior performance (2 weeks: R^2=0.83, r=0.92, MAE=87.84, and RMSE=185.08; 3 weeks: R^2=0.75, r=0.87, MAE=112.41, and RMSE=229.13; and 4 weeks: R^2=0.64, r=0.80, MAE=132.47, and RMSE=276.81) (Table S1 in Multimedia Appendix 13 and Figure 3B-D).

XSL•FO
RenderX

Figure 3. Time series comparison of predicted and observed values by different models for 1- to 4-week-ahead forecasts on the 2023 test set. (A) 1-week-ahead prediction versus observed. (B) 2-week-ahead prediction versus observed. (C) 3-week-ahead prediction versus observed. (D) 4-week-ahead prediction versus observed. LightGBM: Light Gradient Boosting Machine; SARIMA: Seasonal Autoregressive Integrated Moving Average; XGBoost: Extreme Gradient Boosting.



Moreover, the predicted incidence curves closely aligned with the observed epidemic trends, further supporting the reliability of the models (Figure 3). However, some temporal discrepancies were observed in peak incidence predictions, with slight time lags in forecasting epidemic peaks (Figure 3). In addition, the predictive accuracy exhibited a gradual decline as the forecasting horizon extended from 1 to 4 weeks (Figure 3).

Risk Assessment Index

The risk assessment analysis for HFMD in Bao'an District during 2023, based on the prediction results of the stacking model, demonstrated good predictive performance (Table S1 in Multimedia Appendix 14 and Figure 4A-D), with forecast accuracy exceeding 80% across all 1- to 4-week-ahead prediction windows. The 1-week-ahead short-term prediction model achieved exceptional accuracy with forecast accuracy of 96% (Figure 4A and Table S1 in Multimedia Appendix 14).

Figure 4. The results of risk levels of hand, foot, and mouth disease (HFMD) for 1-4 weeks ahead using stacking models. (A) 1-week-ahead HFMD risk levels. (B) 2-week-ahead HFMD risk levels. (C) 3-week-ahead HFMD risk levels. (D) 4-week-ahead HFMD risk levels.

Discussion

Principal Findings

Based on a comprehensive analysis of the impact of systemic factors on HFMD, we innovatively designed an HFMD risk prediction framework by comparing traditional and advanced machine learning prediction models. Our findings suggest that air pollutants and meteorological factors other than SO_2 have a significant effect on the incidence of HFMD (Figure 2 and Figure S1 in Multimedia Appendix 12). In addition, Baidu Index proves to be an effective tool for capturing the epidemic trend of HFMD during the onset week (Figure S1 in Multimedia Appendix 11). While the SARIMA model performs well in 1-week-ahead short-term forecast, advanced machine learning methods incorporating systematical factors performed better for 2- to 4-week-ahead midterm forecasts (Table S1 in Multimedia Appendix 13 and Figure 3). Furthermore, the predicted risk levels based on the advanced forecast models aligned closely with the actual levels (Table S1 in Multimedia Appendix 14 and Figure 4).

Our analysis revealed that meteorological factors exert nonlinear effects on HFMD incidence (Figure 2 and Figure S1 in Multimedia Appendix 12). Temperature exhibits an inverted V-shaped effect on the risk of HFMD, corresponding to optimal conditions for enterovirus survival and transmission [8,9]. Elevated relative humidity enhances HFMD transmission, likely through prolonged virus stability in aerosols [10-12]. Wind speed exerts dual effects: moderate levels reduce risk via particle dispersion [11,46], while extreme winds may increase transmission through environmental disruption. The daily temperature variation and other influences of atmospheric pressure indicate that there is a complex interaction between climate and pathogens, but the mechanism details need further study [8].

Our findings showed a negative nonlinear association between ambient concentrations of PM_2 ., PM_1 , O_3 , and CO and HFMD incidence, consistent with evidence that ozone's virucidal oxidative effects and pollution-induced behavioral changes (eg, reduced outdoor activity) may suppress transmission [9,10,13,14]. Our study found that low-concentration NO_2 exposure exhibited a positive association, likely mediated by NO_2-induced respiratory inflammation and impaired mucosal defenses [10]. The effects diminished beyond a narrow exposure range, indicating threshold-dependent influences. In contrast, SO_2 showed no statistically significant relationship with HFMD incidence, possibly due to regional differences in emissions, atmospheric chemistry, or population susceptibility. Collectively, these findings illustrate the nonlinear relationship between multidimensional environmental exposures and HFMD transmission patterns. These insights informed the development of our multifactorial prediction framework, which improved predictive accuracy.

This study also evaluated the predictive value of web-based search data for the incidence of HFMD. Our results show that the composite Baidu Index and its subindex are effective in capturing epidemiological fluctuations in the week of onset (Figure S1 in Multimedia Appendix 11), which is consistent with previous findings [19]. Compared with traditional passive monitoring that relies on laboratory confirmations and case reports, Baidu search data have the advantage of real-time performance and can reflect epidemic changes 3-7 days in advance, which provides a key supplement for early warning. Similar to previous studies [17,19], this study constructed a multidimensional Baidu comprehensive index by screening core subindicators. This method not only improves the prediction accuracy but also realizes the dynamic tracking and trend prediction of public health concerns by integrating multidimensional search data (rather than a single indicator). It proves the dual advantages of Baidu Index in infectious disease surveillance, which is both timely and comprehensive. These findings not only verify the universality of digital epidemiology in local areas but also provide a paradigm for other low-income countries to optimize infectious disease surveillance by using localized web-based data.

Our study further compared the predictive performance of traditional models and advanced machine learning models on different time scales. The results showed that SARIMA demonstrated higher accuracy in 1-week-ahead short-term forecast than other machine learning models, which is consistent with previous studies in Nanjing [26] and Sabah [27]. The advanced machine learning models exhibited superior predictive capacity for 2- to 4-week-ahead midterm forecasts (Table S1 in Multimedia Appendix 13 and Figure 3). Our findings align partially with a Japanese Long Short-Term Memory Network–based study [29] but achieve earlier detection (2 - 4 weeks) and higher accuracy through multimodel integration. Unlike prior hybrid model studies in Wuhan [33], Chongqing [30], and Xinjiang [32], our multiscale framework uniquely combines predictive performance with optimized model selection across temporal scales, offering more actionable guidance. SARIMA is optimal for rapid response scenarios requiring immediate decisions, as it relies solely on historical incidence data without requiring additional variables [31,33]. Machine learning better supports midterm preparedness planning due to its ability to incorporate diverse predictors, although it demands greater technical capacity. For practical implementation, we recommend aligning model selection with both operational timelines (short-term vs midterm needs) and local data infrastructure, while future research should explore hybrid systems that combine SARIMA's reliability with machine learning's adaptability, alongside translating forecasts into operational risk assessments.

In recent years, the importance of infectious disease risk prediction in disease control has increased. Risk indices for common infectious diseases such as influenza and HFMD have been developed in a number of cities in China, including Shenzhen [37], Zhuhai [35], Beijing [39], and Maanshan [38]. These indices are released to the public to provide early warning of disease risks, thereby raising public health awareness and promoting healthy behaviors with positive social benefits. However, existing risk indices are largely based on notifiable infectious disease reports and sentinel hospital surveillance data, with insufficient consideration of the impact of systemic factors

XSL•FO
RenderX

on disease transmission. Moreover, prediction models often rely on simple multiple linear equations, resulting in suboptimal prediction accuracy. For instance, the predicted concordance rate of the HFMD risk index in Shenzhen was only 77.8% between August 2017 and November 2018 [36]. To overcome previous limitations, this study integrates diverse data sources with advanced machine learning models, developing a more accurate and reliable HFMD risk prediction framework (risk-level accuracy of >90%; Figure 4 and Table S1 in Multimedia Appendix 14). Operationalized in Shenzhen's Bao'an District, our model outperforms existing methods by incorporating multidimensional environmental and epidemiological data to deliver precise 1 - to 4-week forecasts. This provides a robust, data-driven foundation for public health decision-making and proactive community guidance.

Limitations

This study acknowledges several limitations. First, the study was conducted in a limited geographic area, which may restrict the generalizability of the findings. Second, we used average exposure estimates for meteorological factors and air pollutants in Shenzhen rather than individual direct measurement, resulting in exposure measurement errors, but they are likely to be random and nondifferential. Third, the HFMD surveillance data were obtained from a passive monitoring system, which inherently fails to capture all cases, particularly those with mild symptoms that do not warrant medical consultation. Fourth, the transmission of HFMD is influenced by an even more extensive range of factors, including individual vaccination and immune status, lifestyle practices, hygiene practices, contact patterns (particularly in households and childcare settings), indoor environments, ventilation conditions, socioeconomic determinants, and population metrics, such as size and density. Additionally, different types of pathogens may affect the transmission patterns of HFMD, highlighting the importance of laboratory-based pathogen data analysis for identifying the temporal trends and characteristics of HFMD. Finally, with the rapid advancement of artificial intelligence technologies, exploring their effective application in HFMD prediction is an important direction for future research. Future studies should further investigate the roles of these multidimensional factors and integrate more advanced predictive techniques to better understand and monitor the epidemiological trends of HFMD, thereby effectively reducing the risk of infection.

Conclusions

With explorations of the complex influencing pattern for systematic factors, this study developed a prediction model and future epidemic risk assessment framework for HFMD by integrating HFMD incidence data, environmental factors, Baidu Index, and public health interventions using advanced machine learning algorithms. The results highlight the significant role of systematic factors in long-term HFMD predictions and precise risk assessment and demonstrate the model's potential to enhance public health decision-making. Future research should incorporate additional multidimensional factors, including host characteristics, pathogen properties, and socioeconomic conditions, and further explore their interactive effects with more advanced technologies to optimize HFMD risk prediction and control strategies.

Abstract

Background: The advent of robotic total knee arthroplasty (TKA) in the field of orthopedics has caused much discussion on social media. As social media grows, its platforms are becoming an increasingly popular medium for health care–related discussions.

Objective: This study aimed to better understand the current public discussion about robotic TKA on social media. We aimed to characterize these discussions by analyzing their contributors, the general sentiment, the temporal trends, and the content.

Methods: A comprehensive search of the Twitter database for academic research was performed from inception (March 2006) to April 1, 2023, to identify all tweets related to robotic TKA. General data regarding the tweets and the accounts were retrieved. ChatGPT-4o (OpenAI) was used to categorize the post's content and the accounts into different categories developed via iterative testing. The content was categorized using a rule-based classification algorithm developed using Python to assign categories based on keyword presence, phrase matching, and syntactic patterns. Regarding the accounts, an automated keyword-based rule engine was implemented in Python to classify accounts based on the account's name and description. We used a lexicon-based natural language processing Python library, via ChatGPT-4o, to assign a sentiment to the tweets and conducted subgroup sentiment analysis.

Results: A total of 2000 tweets were retrieved for analysis. Account analysis revealed that the most prevalent account categories were "medical professionals" (619/2000, 31.0%), "patients and community" (274/2000, 13.7%), and "media and publications" (268/2000, 13.4%). Content analysis revealed that the most prevalent tweet themes were "technology and innovation" (550/2000, 27.5%), "advertising and promotion" (176/2000, 8.8%), and "research and data" (172/2000, 8.6%). Sentiment analysis showed that 61.6% (1231/2000) of the tweets had a positive sentiment, while 9.2% (183/2000) were neutral, and 29.3% (586/2000) had a negative sentiment. Accounts categorized as "institutions" had the highest prevalence of positive sentiment (165/229, 72.1%), while accounts categorized as "media and publications" had the highest prevalence of negative sentiment (88/268, 32.8%). The number of tweets relating to robotic TKA has been steadily rising since 2016, with a peak incidence of 402 (20.1%) tweets published in 2022.

Conclusions: The increased number of tweets with a positive sentiment suggests a positive outlook toward robotic TKA. Institutions had the highest prevalence of positive sentiment, suggesting a possible bias toward positive reporting of robotic TKA, likely for commercial reasons. Media and publications had the highest prevalence of negative sentiment, which may represent skepticism and bias toward negative reporting on robotic technologies in health care. Medical professionals contributed significantly to the discussion about robotic TKA, while patient involvement was relatively small. The number of tweets relating to robotic TKA has been steadily growing since 2016, which indicates that robotic TKA has been gaining in popularity over recent years.

(JMIR Infodemiology 2025;5:e69883) doi:10.2196/69883

KEYWORDS

social media; twitter; knee replacement; arthroplasty; robotic; robotic surgery; patient; clinician; researcher

Introduction

Background

Total knee arthroplasty (TKA) is one of the most common procedures in orthopedics [1]. As of 2019, more than 480,000 primary TKAs were being performed under Medicare in the United States alone [2]. TKA involves removing the affected articular surfaces of the knee and replacing them with polyethylene, metal, or other prosthetic components [3]. TKA is known to be a safe procedure with a high satisfaction rate [4]; however, up to 20% of patients remain unsatisfied with their clinical result [5]. Several factors can contribute to patient dissatisfaction, such as instability of the prosthesis, medial joint

XSL•FO
RenderX

laxity, and persisting pain, among others [4]. A multitude of solutions has been proposed to improve patient satisfaction rates. One of the most promising solutions has been the use of robotic technology. Robotic technology has already been used to improve surgical outcomes in various fields such as general surgery, obstetrics and gynecology, cardiology, and ophthalmology [6]. Over recent years, robotic-assisted TKA has gained traction as an interesting avenue to improve surgical outcomes and patient satisfaction by aiding in precisely realigning the mechanical axis, enhancing ligament balance, and optimizing implant positioning [7].

Rationale

The advent of robotic TKA in the field of orthopedics has caused much discussion on social media. As social media grows, its platforms are becoming an increasingly popular medium for health care–related discussions. A study published in 2020 found that 17.1% of the health information proposed by Google in response to arthroplasty questions originated from social media websites [8]. Among all social media platforms, Twitter (subsequently rebranded as X) is the social media platform that is most used for health care communication [9]. Authors included in this study have previously characterized, via analysis of sentiment, content, contributors, and temporal trends, social media discussions regarding glioblastoma, cervical myelopathy, anterior cruciate ligament injury prevention, epilepsy, pediatric spine surgery, among others [10-14]. Previous research has also analyzed social media discussions regarding robotic total hip arthroplasty [15], but no previous study has analyzed social media discussions surrounding TKA or robotic TKA, despite TKA being one of the most common procedures in orthopedics [1]. By analyzing the content of these discussions, it is possible to reveal important trends, such as decreased trust in a specific procedure, which can subsequently be addressed by physicians, researchers, and the industry. This study aimed to better understand the current public discussion about robotic TKA on social media. Similar to previously published literature, we aimed to characterize these discussions by analyzing their sentiment, content, contributors, and temporal trends.

Methods

Search Strategy

The methodology used in this study is based on previous studies detailing social media discourse in various health care fields [11,13,16]. A thorough search of Twitter's application programming interface (API) for academic research was performed from inception (March 2006) to April 1, 2023. We used the following search terms: (total knee replacement OR total knee arthroplasty OR knee replacement OR knee arthroplasty OR TKA OR TKR) AND (robot OR robotic).

Accounts

We excluded duplicate accounts, accounts with fewer than 10 tweets, bots, and accounts with fewer than 15 followers from our study. User accounts were classified as bots either based on usernames explicitly indicating their bot nature or if all tweets from the account consisted of retweets with identical formatting. The following data were extracted for further analysis: account location, number of followers, number of tweets, and year joined Twitter. We used ChatGPT-4o [17] to categorize the accounts into different categories. The following prompt was inserted into ChatGPT-4o:

> *I am in the process of writing a scientific article looking at Tweets discussing robotic total knee arthroplasty on Twitter. The excel file included in this message contains the raw data of 2000 tweets. Row B contains the account username, while row E contains the description of the author's account. Classify the accounts into the following categories, used by previous studies: "foundation," "medical center," "business," "journal," "MD/researcher," "news channel," "patient/caregiver," "support group" and "other." If there are better categories that can be used, please use them and compare the data. Tell me how I can make this prompt better for you.*

The output stated that the categories detailed in Table S1 in Multimedia Appendix 1 significantly decreased the number of accounts categorized as "other," and ensured clarity, mutual exclusivity, and comprehensive coverage of account categories. Chat-GPT4o used an automated keyword-based rule engine that was implemented in Python to classify accounts based on the account's name and description. The "other" category included accounts that either had no available descriptions and whose names could not hint toward their origin, or accounts that could not be categorized in any of the proposed categories. A sample of 20 accounts was reviewed by one independent evaluator (CD) for the validity of the classification.

XSL•FO
RenderX

Table . Examples of tweets categorized as positive, neutral, and negative.

Sentiments	Example of tweet content
Positive	• *"Our patients travel great distances to consult with our orthopedic team... approved to purchase VELYS robotic-assisted solution."* • *"Dr. X (censored) has successfully conducted robotic hip & knee joint replacement surgery on three patients."*
Neutral	• *"Orthopaedic surgeons are now performing total knee replacement surgeries using robotic systems that do not require CT scans."* • *"M. X (censored) sharing her experience after total knee replacement surgery by Dr. X (censored)."*
Negative	• *"Completely agree — present cost of the robot is not justified. But if studies show it improves outcome, cost may come down like electric cars. Otherwise, it will be remembered as a very expensive marketing tool."* • *"Nothing will replace human touch, but what can this robot do that the human hand has failed to achieve?"*

Tweets

After duplicate removal, all retrieved tweets were considered eligible. For each tweet, the date of the tweet, the number of retweets, replies, quotes, and likes, as well as the presence of media, tagging, hashtags, and links, were retrieved. All included tweets were then categorized by ChatGPT-4o into one of the content categories presented in Table S2 in Multimedia Appendix 1. The following prompt was inserted into Chat-GPT4o:

> *"Using the same raw data as previously used, categorize the content (row G) into one of the following categories, used by previous studies: "advertising," "awareness," "experience," "research," and "other." If there are better categories that can be used, please use them and compare the data. Tell me how I can make this prompt better for you.*

The output stated that the categories detailed in Table S2 in Multimedia Appendix 1 significantly decreased the number of accounts categorized as "other," and ensured clarity, mutual exclusivity, and comprehensive coverage of tweet content. A rule-based classification algorithm was developed by Chat-GPT4o using Python to assign categories based on keyword presence, phrase matching, and syntactic patterns. A sample of 20 tweets was reviewed by one independent evaluator (CD) for validity of the classification.

Statistical Analysis

We used descriptive statistics (median, IQR) to analyze the different data points retrieved regarding the accounts and the tweets. Statistical significance was reached if $P<.05$. R (R Core Team; version 4.1.3) was used to conduct all statistical analyses.

Sentiment

ChatGPT-4o was used to determine the tone of the tweet (ie, the sentiment). The following prompt was inserted into ChatGPT-4o:

> *Using the same raw data as previously used, please classify the text of the tweet (row G) into the following sentiment categories: negative, neutral or positive. Please detail the methodology used to analyze the sentiment of the Tweets.*

ChatGPT-4o subsequently analyzed the tone of the tweets using TextBlob, a lexicon-based natural language processing Python library [18] that uses a predetermined dictionary of words, which analyzes data semantically. Chat-GPT4o opted to use the same lexicon-based natural language processing library (TextBlob) as used by previous studies with similar methodologies [11,12,14]. Regarding the sentiment analysis, TextBlob attributed a score to the tweet's polarity and subjectivity. The polarity score was used to represent the sentiment. A polarity score of −1 represented the most negative tweets, whereas a score of +1 represented the most positive tweets. The subjectivity score (range 0 - 1) was used to assess whether a tweet was objective (score of 0) or subjective (score of 1). Finally, the algorithm assigned a label based on the polarity scores; a score <0 represented a negative sentiment, a score of 0 represented neutral sentiment, and a score >0 represented a positive sentiment. Subjectivity scores were retained to provide additional context for future qualitative analysis but were not used as primary classification criteria. Once the sentiment analysis was completed, we conducted subgroup analyses within the different account categories to identify trends. Table 1 presents examples of tweets categorized as positive, neutral, and negative.

Ethical Considerations

The data obtained in our study was freely obtained from Twitter's API for Academic Research. As this is publicly available data, this study does not meet the inclusion criteria for approval by an institutional board of the Canadian Tri-Council Policy Statement [19]. All social media identifiers (names, handles) were removed to preserve confidentiality.

Results

Overview

A total of 7339 tweets were obtained using our search criteria. A random sample of 2000 tweets was retrieved for further

XSL•FO
RenderX

analysis. Regarding the accounts from which the tweets originated, the median number of followers was 858 (IQR 207-3276) and the median number of tweets per author was 3129.5 (IQR 863.5-11581). Regarding the tweets, the mean retweet count was 0.80 (SD 2.95), the mean reply count was 0.27 (SD 1.45), the mean like count was 3.01 (SD 10.50), and the mean quote count was 0.10 (SD 0.51).

Accounts

Manual review of account categorization revealed a concordance of 80% (16 tweets out of 20). Account analysis revealed a high prevalence of accounts categorized as "medical professionals" (619/2000, 31%). Despite our efforts to develop a categorization scheme that covered most of the accounts, the "other" category remained prevalent (523/2000, 26.2% of total accounts). Accounts categorized as "other" included accounts with descriptions such as the following: "*I live in San Jose, ca.*" The name of the account has been censored for privacy purposes, but does not provide information regarding account origin. Such accounts are difficult to categorize in a succinct categorization scheme. Finally, accounts related to "institutions," "media and publications," and "patients and community" were similarly prevalent at around 13% (229-274/2000) each. These findings are summarized in Table 2.

Table . Percentage of accounts per account category (N=2000).

Account categories	Accounts, n (%)
Industry and business	87 (4.4)
Institutions	229 (11.5)
Media and publications	268 (13.4)
Patients and community	274 (13.7)
Other	523 (26.2)
Medical professionals	619 (31.0)

Tweets

Manual review of tweet categorization revealed a concordance of 75% (15 tweets out of 20). Content analysis revealed a high prevalence of tweets categorized as "other" (676/2000, 33.8%), while "technology and innovation" accounted for 27.5% (550/2000). "Advertising and promotion," "research and data," and "experience" accounted for about 8% (148-176/2000) of the content, respectively, while "news and institutional highlights," "awareness, education and events," and "surgical practice and technique" were much less prevalent. These findings are summarized in Table 3.

Table . Percentage of tweets per content category.

Content categories	Percentage of posts
Surgical practice and technique	3.4
Awareness, education, and events	5.3
News and institutional highlights	5.4
Experience	7.4
Research and data	8.6
Advertising and promotion	8.8
Technology and innovation	27.5
Other	33.8

Sentiment

On sentiment analysis, 183 of 2000 (9.2%) tweets had a neutral sentiment, 586 of 2000 (29.3%) tweets had a negative sentiment, and 1231 of 2000 (61.6%) tweets had a positive sentiment. Subgroup analysis was notable for a high prevalence of positive sentiment within the "institution" group (165/229, 72.1%). Meanwhile, "industry and business" had the highest prevalence of neutral sentiment (12/87, 13.8%), and the "media and publications" group had the highest prevalence of negative sentiment (88/268, 32.8%). These findings are summarized in Table 4.

Table . Subgroup sentiment analysis.

Author category	Negative, n/n (%)	Neutral, n/n (%)	Positive, n/n (%)
Industry and business	23/87 (26.4)	12/87 (13.8)	52/87 (59.8)
Institutions	51/229 (22.3)	13/229 (5.7)	165/229 (72.1)
Media and publications	88/268 (32.8)	21/268 (7.8)	159/268 (59.3)
Medical professionals	199/619 (32.1)	41/619 (6.6)	379/619 (61.2)
Other	152/523 (29.1)	71/523 (13.6)	300/523 (57.4)
Patients and community	78/274 (28.5)	23/274 (8.4)	173/274 (63.1)

Temporal Dynamics

The number of tweets relating to robotic TKA has been steadily rising over the years, with a peak incidence of 402 of 2000 (20.1%) tweets published in 2022. Table 5 presents the number of Tweets for each year from 2010 to 2023. The number of tweets for the year 2023 relates to the number of tweets published before April 1, 2023, when the data extraction was done.

Table . Number of tweets per year from 2010 to 2023 (N=2000).

Year	Tweets, n (%)
2010 - 2013	108 (5.4)
2014	30 (1.5)
2015	63 (3.2)
2016	55 (2.8)
2017	142 (7.1)
2018	314 (15.7)
2019	155 (7.8)
2020	249 (12.5)
2021	341 (17.1)
2022	402 (20.1)
2023	141 (7.1)

Discussion

Principal Findings

This is the first study to explore the landscape of social media discussions regarding robotic TKA. Our data demonstrated a high prevalence of tweets with a positive sentiment (1231/2000, 61.6%). Accounts categorized as “institutions” had the greatest prevalence of positive sentiment (165/229, 72.1%), while accounts categorized as “media and publications” had the highest prevalence of negative sentiment (88/268, 32.8%). Medical professionals contributed significantly to the discussion about robotic TKA (619/2000, 31.0% of accounts), while patient involvement was relatively small (274/2000, 13.7% of accounts). The number of tweets relating to robotic TKA has been steadily growing since 2016.

Sentiment

Our sentiment analysis showed that 61.6% (1231/2000) of the tweets had a positive sentiment, while 9.2% (183/2000) were neutral, and 29.3% (586/2000) had a negative sentiment. Studies with similar methodologies have consistently reported lower percentages of tweets with a positive sentiment. For instance, similar studies assessing tweets regarding pediatric spine surgery, cervical myelopathy, and glioblastoma reported a positive sentiment in 46.5%, 38.6%, and 43.6% of the tweets, respectively [10,11,14]. A recent study about social media discussions of anterior cruciate ligament injury prevention revealed a positive sentiment in 45.1% of the tweets [12]. TKAs are known to have a high satisfaction rate [4], and the elevated prevalence of positive sentiment in the tweets discussing robotic TKA on Twitter could be a reflection of this high satisfaction rate. Furthermore, subgroup analysis revealed that “medical professionals” had a highly prevalent positive sentiment within their tweets (379/619, 61.2%), and they represented the most prevalent account category (619/2000, 31.0% of the accounts).

On subgroup analysis, our data showed that “institutions” had the highest prevalence of positive sentiment (165/229, 72.1%). Indeed, tweets from institutions often boasted about new robotic-assisted TKA capacities and were likely biased towards positive phrasing for commercial reasons. Tweets with a positive sentiment and originating from an account categorized as “institution” included the following:

> *great news at X (censored institution) yesterday dr X (censored) performed first navio robotic assisted total knee replacement.*

XSL•FO
RenderX

Previous literature has reported that hospital promotions tend to overstate benefits, and sometimes omit risks associated with robotic surgery [20,21]. On the other hand, the group with the highest prevalence of negative sentiment within their tweets was "media and publications," which likely represents skepticism from news outlets toward robotic technologies in surgery. Tweets with a negative sentiment and originating from an account categorized as "media and publications" included the following:

> *knee surgery isnt as bad as it used be […] now that robots are giving docs helping hand.*

Although this might initially appear as a positive tweet, the phrasing presents knee surgery as a previously "bad" operation, which brings the natural language processing algorithm to correctly assign it a negative tone. Previous literature has reported similar trends from news outlets. For instance, a paper published in the *Journal of Robotic Surgery* reported that, out of 27 journal articles analyzed, all 27 reported disadvantages of robotic surgery, while only 7/27 (26%) reported findings favoring robotic approaches [22].

Concordance Analysis

Discordance between manual categorization and ChatGPT-4o's categorization of the content and the accounts appears to be related to insufficient context and syntax errors. For instance, the following account description was categorized as "other" by ChatGPT-4o:

> *''In compliance with federal and state privacy laws, do not include any private health information in any message you send us through this channel.*

This account was related to a medical institution and was thus manually categorized as "institution" by the independent reviewer. However, because of missing context and keywords, ChatGPT-4o categorized it as "other." Similarly, the following content was categorized as "other" by Chat-GPT4o:

> *experienced high volume surgeons robotic total knee arthroplasty was longer more costly procedure than manual total knee arthroplasty with similar lengths stay complications.*

This tweet referred to a research paper and was thus manually categorized as "research and data" by the independent reviewer. However, considering the lack of keywords and syntax errors, ChatGPT-4o classified it as "other."

Actors Discussing Robotic Total Knee Arthroplasty

Our results showed that most of the accounts discussing robotic TKA on Twitter were related to the following categories: "medical professionals" (619/2000, 31%), "other" (523/2000, 26.2%), and "patients and community" (274/2000, 13.7%). Similar studies have reported widely different results regarding contributors to social media discussions. In a study with a similar methodology about pediatric spine surgery, it was found that 79% of the tweets originated from a patient or caregiver, while only 3.3% from a physician or researcher [14]. In another similar study about anterior cruciate ligament injury prevention on Twitter, patients and caregivers represented 55.7% of the accounts [12]. On the other hand, Elkaim et al [11] reported that, similarly to our data, 37.8% of the accounts discussing degenerative cervical myelopathy on social media originated from medical doctors or researchers, while 23.5% originated from patients or caregivers. The significant contribution of medical professionals to the discussion surrounding robotic TKA on Twitter may be explained by the fact that robotic-assisted surgery constitutes a highly debated topic within the health care field, notably regarding doubts about the cost-benefit ratio [23] and some evidence demonstrating nonsuperiority to laparoscopic surgery [24,25]. Regarding the decreased contribution of "patients and community" to the discussion, it is possible that patients and caregivers discussing robotic TKA on Twitter do not specify the robotic-assisted aspect of the surgery in their tweets and are subsequently not included in our search of the API. To verify this hypothesis, a future study could be designed to compare TKA and robotic TKA discussions on Twitter.

Content of the Tweets

The diversity of themes observed in the tweets reflects the multifaceted nature of discussions surrounding robotic TKA on Twitter. The most prevalent tweet categories were "other" (676/2000, 33.8%), followed by "technology and innovation" (550/2000, 27.5%) and "advertising and promotion" (176/2000, 8.8%). Tweets categorized as "other" included tweets such as:

> *why do they call it knee replacement not were turning you into robot" or "even robotic knee replacement needs your clever multimodal analgesic cocktail.*

Such content is difficult to categorize in a succinct categorization scheme. Other studies about social media discussions regarding different medical procedures have used different categorization schemes for content. Fortunately, a category dedicated to "research" is often found in other articles. Levett et al [14] found that 40.9% of tweets on Twitter relating to pediatric spine surgery discussed research, while Elkaim et al [11] found that 45% of tweets on Twitter relating to cervical myelopathy discussed research [11]. "Research and data" accounted for only 8.6% (172/2000) of the content related to robotic TKA. This might affect the overall accuracy of the content related to robotic TKA on social media, although most accounts discussing robotic TKA on Twitter were medical professionals, which might attenuate this lack of accuracy. As stated in the Methods section, many tweets could not be categorized into the categories proposed in our study because of their unclear general content.

Temporal Dynamics

Our results showed that the number of tweets relating to robotic TKA increased substantially in the year 2020 (from 155 in 2019 to 249 in 2020) and continued to grow in the years that followed (up to 402 in 2022). Similar studies have reported different trends. Elkaim et al [11] reported a surge in tweet volume regarding degenerative cervical myelopathy in 2018 - 2019 and a significant decrease in 2020 - 2021. Similarly, Levett et al [12] reported a surge in tweet volume regarding anterior cruciate ligament injury prevention in 2018 - 2019 and a subsequent decrease in the following years. It appears that tweets relating to robotic TKA have also experienced a surge in 2018. However, the tweet count has been steadily rising since. It has already been reported in the literature that the presence of physicians

XSL•FO
RenderX

has steadily grown on Twitter from the year 2016 to 2020 [26], and considering that "medical professionals" accounted for more than 30% (619/2000) of the accounts discussing robotic TKA on social media, it is unsurprising that robotic TKA has experienced increased popularity during this timeframe.

Limitations and Directions for Future Research

While our study provides valuable insights into the discussions surrounding robotic TKA on social media, it is essential to address certain limitations. First, our results are based on a single social media platform. Although Twitter is considered the most popular social media platform for health care discussions [9], including more social media platforms would provide a more complete dataset. Including more social media platforms remains difficult, as Twitter is the only social media platform with easily accessible, extensive data. Second, a significant proportion of the accounts (523/2000, 26.2%) and the content (676/2000, 33.8%) were categorized as "other" because they were not compatible with the categories proposed by our study, or because they simply could not be classified (eg, no author description and a name unrelated to an account category). More studies are needed to establish standardized categorization schemes of tweets and accounts that can be reproduced in different health care domains. More research is also needed to compare different orthopedic procedures. This could reveal important trends, such as a decreased trust in a procedure, which can subsequently be addressed by physicians, researchers, and the industry.

Conclusions

This is the first study to explore the landscape of social media discussions regarding robotic TKA. The increased number of tweets (61.6%) with a positive sentiment reflects a positive outlook towards robotic TKA on social media. Accounts categorized as "institutions" had the greatest prevalence of positive sentiment (165/229, 72.1%), suggesting a possible bias towards positive reporting of robotic TKA, likely for commercial reasons. Accounts categorized as "media and publications" had the highest prevalence of negative sentiment (88/268, 32.8%), which may represents a skepticism and a bias toward negative reporting on robotic technologies in health care. Medical professionals contributed significantly to the discussion about robotic TKA (619/2000, 31.0% of accounts), while patient involvement was relatively small (274/2000, 13.7% of accounts). The number of tweets relating to robotic TKA has been steadily growing since 2016, which indicates that robotic TKA has been gaining in popularity over recent years.

Acknowledgments

We used the generative AI tool ChatGPT-4o by OpenAI [17] to categorize the accounts and the tweets and conduct the sentiment analysis.

Abstract

Background: Cannabis is the third most consumed drug worldwide, with its use linked to a high number of substance use disorders, particularly among young men. Associated mortality causes include traffic accidents and cardiovascular diseases. The global expansion of cannabis legalization has sparked debates about its impact on risk perception, with risk perception decreasing in countries with permissive laws. Social media analysis, such as on Twitter (subsequently rebranded as X), is a useful tool for studying these perceptions and their variation by geographic region.

Objective: This study aims to analyze Twitter users' perceptions of cannabis use and legalization, taking into account the geographic location of the tweets.

Methods: A mixed methods approach was used to analyze cannabis-related tweets on Twitter, using keywords such as "cannabis," "marijuana," and "hashish." Tweets were collected from January 1, 2018, to April 30, 2022, in English and Spanish, and only those with at least 10 retweets were included. The content analysis involved an inductive-deductive approach, resulting in the classification of tweets into thematic categories, including discussions on legalization.

Results: The tweet analysis showed that in America, Europe, and Asia, political discussions about cannabis were the most common topic, while personal testimonies dominated in Oceania and Africa. In all continents, personal experiences with cannabis use were mostly positive, with Oceania recording the highest percentage (1642/2695, 60.93%). Regarding legalization, Oceania also led with the highest percentage of tweets in favor (1836/2695, 68.13%), followed by America and Africa, while support in Europe and Asia was slightly lower, with about half of the tweets in favor.

Conclusions: The political debate has been the most frequently mentioned topic, reflecting the current situation in which legislative changes are being discussed in many countries. The predominance of opinions in favor of legalization, combined with the prevalence of positive experiences expressed about cannabis, suggests that the health risks associated with cannabis use are being underestimated in the public debate.

RenderX

Introduction

Cannabis is the third most consumed drug worldwide, after alcohol and tobacco. It is estimated that 219 million people used cannabis in 2021, which corresponds to 4% of the global population. In 2021, approximately 46% of countries reported that cannabis was the drug linked to the highest number of substance use disorders [1].

It is estimated that 22.1 million people worldwide had a cannabis use disorder [2], which is more common in men than in women. A study conducted in Australia, Europe, and the United States revealed that the average age at which cannabis use disorder manifests is 22 years [3]. The most frequent causes of mortality associated with cannabis use are traffic accidents, suicide, and cardiovascular and pulmonary diseases [4,5]. A study conducted in New Zealand concluded that the risks of driving under the influence of cannabis could be greater than the risks of driving under the influence of alcohol [6].

The increasing global legalization of cannabis is generating significant political and social debate. It is necessary to study the impact of legislative changes on the public's perception of risk. Studies have shown that in countries where cannabis use has been legalized, the perception of risk has decreased [7]. According to the Survey on Drug Use in Secondary Education in Spain (ESTUDES) conducted in 2023, 12.9% of respondents stated that the legalization of cannabis would encourage them to try it [8].

In this context, analyzing social media posts is a useful tool for understanding public opinion, which can help to identify factors that influence cannabis use. Social media platforms are increasingly being used by researchers to monitor public health [9], as these platforms capture more sincere and spontaneous opinions than conventional opinion studies conducted in hospital settings [10,11]. A systematic review that analyzed the advantages and disadvantages of using Twitter in public health research concluded that it is a valuable tool for identifying social concerns and information needs on a given topic [12,13]. Previous studies have demonstrated the effectiveness of content analysis as a public health tool for analyzing and studying issues related to drugs [14-17].

In this study, we aim to understand how attitudes toward cannabis and its legalization vary by geographic region through the analysis of tweets made on Twitter. We hypothesize that in countries with more permissive cannabis use and purchase laws, the perception of risk decreases.

Methods

Search Strategy and Data Collection on Twitter

This mixed method analysis, both quantitative and qualitative, focused on the content of tweets related to cannabis posted on the social network Twitter. We collected all tweets using the following keywords (in English or Spanish): cannabis, marijuana, and hashish. We included those tweets that met the following inclusion criteria: (1) Public tweets, (2) tweets containing any of the aforementioned keywords in the text, (3) published between January 1, 2018, and April 30, 2022, (4) written in English or Spanish, and (5) having received at least 10 retweets. The inclusion criteria were selected to capture a broad and representative social media discussion on the topic. We decided to collect and analyze tweets over a period of more than 4 years to cover the broadest possible timeframe, making the study more representative. If a timeframe of only days or weeks is selected, conversations may be heavily influenced by specific events or legislative changes (eg, a change in cannabis regulations in a particular country). Most studies of this nature are limited to days, weeks, or months. Very few studies analyze social media posts (or other internet spaces) over multiple years. We could have selected a longer timeframe, but the economic cost would have increased significantly.

The tool we used to collect the tweets is Tweet Binder, which has been widely used in previous research and can access 100% of public tweets. In addition to the tweet text, this tool provides the number of retweets and likes for each tweet, as well as the date they were published, a link to the tweet in its context, the user description, and geolocation. The number of retweets and likes each tweet received is an indicator of the interest generated by the corresponding content among users.

Content Analysis Process

Using the previously mentioned search criteria, we collected 69,033 tweets in Spanish and 181,217 tweets in English. Next, the remaining tweets were analyzed using a mixed inductive-deductive approach to develop a codebook to classify the tweets based on key thematic categories. A small subset of tweets (n=300) was manually classified by 2 members of the research team. After discussing discrepancies and adjusting the codebook by consensus, 2000 more tweets were analyzed. Finally, an automated and computerized classification of the remaining larger subset of tweets (n=250,250) was performed.

Tweets were classified as classifiable or nonclassifiable. A tweet was considered nonclassifiable when its content was unrelated to the objectives of this work, if the content was insufficient to contain relevant information, or if it was written in a way that made its meaning uncertain. For each classifiable tweet, the content was analyzed according to the following topics: (1) tweet theme, (2) personal experience with the drug, and (3) legalization. The classification criteria and examples of tweets are shown in Table 1.

XSL•FO
RenderX

Table . Category, definitions, and examples of classification. Usernames and personal names were removed.

Categories	Examples
Tweet theme	
Political discussion (refers to both police or social or political complaint or claim [for or against])	• On July 1 2021 the New Jersey Supreme Court announced procedures for automatic vacation dismissal and expungement of certain marijuana- and hashish-related cases.
General information (refers to when talking about more scientific issues).	• "Podemos" (communism) is always against progress and freedoms and against health. It calls for the legalization of cannabis, which destroys neurons and willpower. It causes memory and learning problems, dependency, anxiety, depression, lung diseases, cancer, arrhythmia, and psychosis...
Sale and advertising (cannabis is advertised)	• The Assad regime has transformed into one of the world's leading narcotics enterprises. Hashish is among its major drug exports but the most lucrative is captagon a mild stimulant pill consumed recreationally throughout the Middle East
Testimonials (regarding consumption, experience, more from the opinion of drug users, or families or friends)	• Second-Hand Smoke Has Never Been Funnier'-Reporter: "Burning behind me is 8 1/2 tons of heroin opium hashish & other narcotics…(uncontrollable giggling)"-This is what happens when you stand too close to a pile of burning drugs. It's like taking a toke from a HUGE joint
Trivialization (minimization of the consequences of consumption, stigmatization, and humorous tweets)	• This Lebanese town's residents rely on hashish to survive. The problem? It is all illegal
Personal experience with cannabis[a]	
Negative	• The professor MUST 1st have to answer: WHAT KIND OF ENVIRONMENT PRODUCES VIOLENT YOUTHS AND FANATICAL-HASHISH SMOKING TERRORISTSlacking enterprise and ingenuity for growth?It takes a special breed of people to persevere with leeches...I commend all Biafransincluding Igbos.
Positive	• Cannabis Cafe • smoke while you eat • add thc seasoning to your food • take everything home (weed + food) • food is actually torch10/10 recommend
Legalization	
No mention (or against)	• Again ..The state of terrorism mercenaries and drugs (Bashar Assad and his gangs): The Jordanian army foiled an attempt to smuggle a huge shipment of drugs from Syria which consisted of nearly 1 million and 21 thousand pills of captagon and 35 hashish bricks.
In favor of legalization	• Finally Morocco legalises it most famous export. They've been growing marijuana in the mountains for centuries and Moroccan hashish is cherished in Europe. This week parliament is debating a cannabis legalisation bill for "medicinal use" ( )

[a]Personal experience with cannabis, whether through acquaintances, friends, family members, or personal use, or related to social events associated with its consumption.

Machine Learning Classifier

The methodology followed in this project has been validated in prior research studies [18,19]. First, a preprocessing of the database should be executed. This preprocessing involves a translation of the non-English tweets to English using Google Translate (3.1.0a0 version) and a normalization of the tweets by removing special characters, splitting negative contractions, and removing repetitions. Then, we use a pretrained network called BERTWEET, trained on 850 million English tweets [20], to classify cannabis-related tweets. Since BERTWEET was not initially designed for the specific classification categories, fine-tuning was performed. Manually classified tweets were randomly divided into an 80% training subset and a 20% testing subset. The training subset was used to fine-tune the network, while the testing subset was used to validate its performance. In addition, to address some imbalanced categories (where certain options had a higher number of tweets compared with

XSL•FO
RenderX

others), text augmentation was performed using the library called textattack (0.3.8 version; (QData research group) [21].

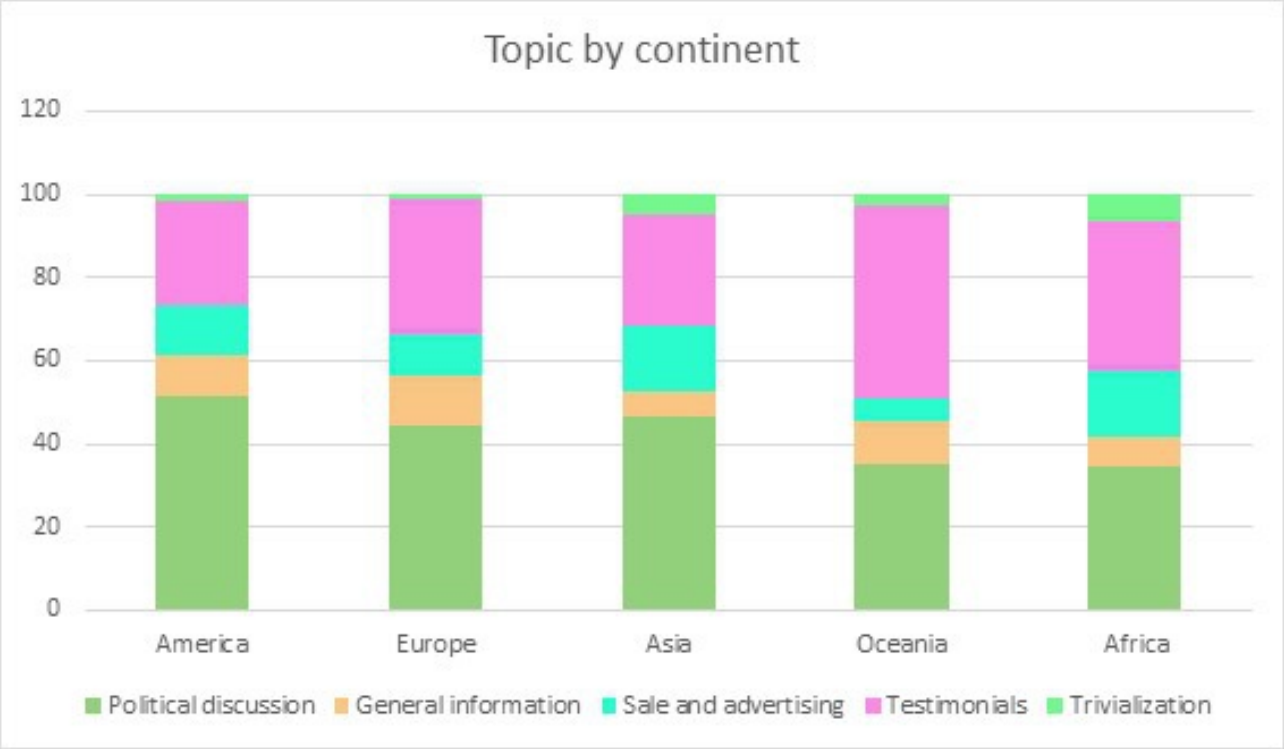
Statistical Analysis

The results were presented in tables or figures, showing the percentage of tweets in each category. To compare the proportions of tweets between categories, Pearson chi-square test was used, yielding a *P* value indicating statistical significance.

Choropleth maps were generated as a visualization tool to depict the global distribution of tweets. In addition, these maps were used to illustrate the geographic distribution of tweets expressing support for the legislation and exhibiting a sentiment favorable to cannabis.

The statistical analyses were performed using the software packages STATA v16 (StataCorp) and Microsoft Excel.

Ethical Considerations



This study was conducted in accordance with the ethical research principles outlined in the Declaration of Helsinki (seventh revision, 2013) and received approval from the Ethics Committee of the University of Alcalá (CEID/2023/6/118). In addition, it did not directly involve human subjects or include any interventions. Only publicly available tweets were used (subject to universal access via the internet in accordance with the Terms of Service that all users agree to on Twitter). In any case, we have taken care not to disclose any usernames directly in this work and have avoided citing information that could identify specific individuals.

Results

Out of the total number of classifiable tweets (206,526), 68.81% (142,139/206,526) had geolocation data. The continent with the highest number of tweets is America, accounting for 54.23% (112,004/206,526) of the total, followed by Europe with 9.21% (19,024/206,526), Asia with 2.39% (4946/206,526), Africa with 1.68% (3470/206,526), and Oceania with 1.3% (2696/206,526).

Regarding the distribution of tweets by theme, in America, Europe, and Asia, the most common theme is political discussion, while in Oceania and Africa, the most frequent theme is personal testimonies (Figure 1). The *P* value is <.001, indicating statistical significance.

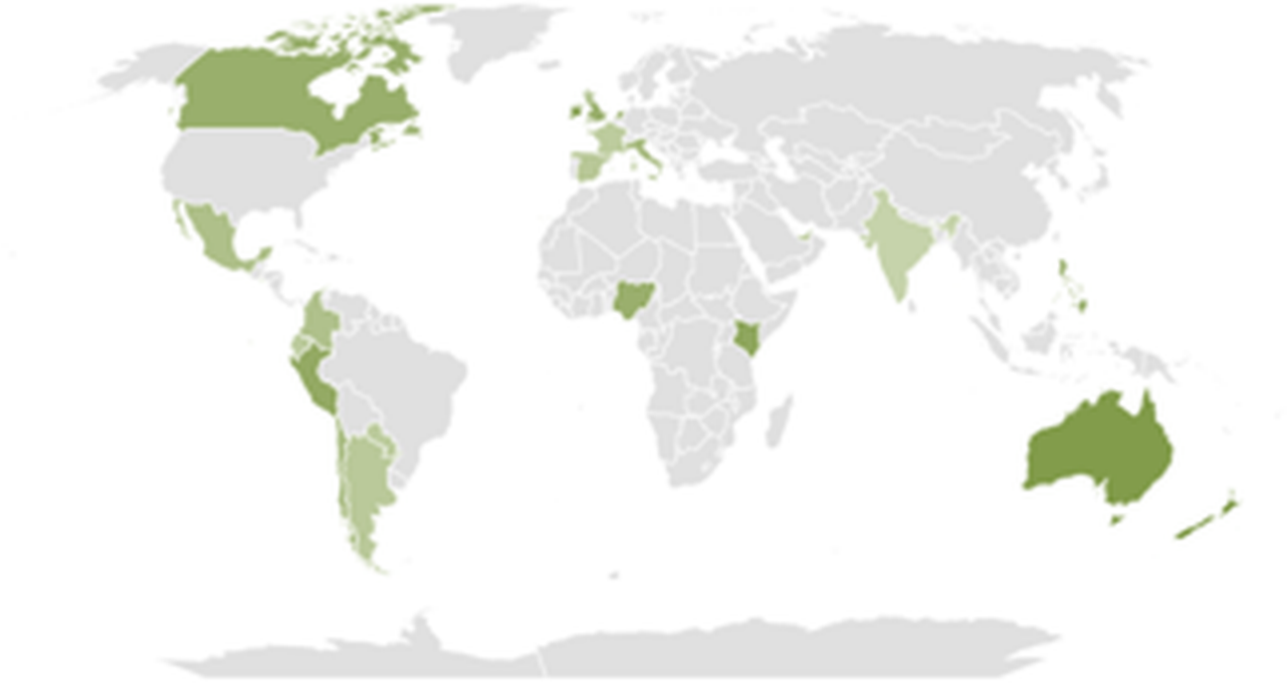


Figure 1. Thematic distribution by continent.

Regarding personal experiences related to cannabis consumption, on all continents, there are more tweets describing positive experiences than negative ones, with Oceania having the highest percentage of such tweets. Specifically, in Oceania, we found that 60.93% (1642/2695) of the tweets described a positive experience, while only 9.09% (245/2695) described a negative experience, with 29.98% of tweets not expressing any opinion on the matter. In Africa, 50.63% (1757/3470) of tweets described a positive experience and 10.81% (375/3470) a negative one; in Europe, 40.49% (7702/19,024) described a positive experience and 10.19% (1939/19,024) a negative one; in America, 40.03% (44,837/112,004) described a positive experience and 8.16% (9144/112,004) a negative one; and in Asia, 34.07% (1685/4946) described a positive experience and 11.89% (588/4946) a negative one (Figure 2). *P* value <.001 indicates statistical significance.

XSL•FO
RenderX

Figure 2. Percentage of tweets of positive experience with cannabis by continent. In dark green are the countries with the highest percentage of tweets in this category, in light green are those with fewer tweets. In gray are the geographical regions where there are no tweets about positive experiences.

Finally, regarding cannabis legalization, Oceania has the highest percentage of tweets in favor of legalization, with more than double the number of tweets supporting legalization (1836/2695, 68.13%) compared to those against it (859/2695, 31.87%). In America and Africa, the percentage of tweets in favor is also higher than those expressing opposition to legalization, with 59.21% (66,313/112,004) and 53.54% (1858/3470) of tweets in favor, respectively. In Europe and Asia, the proportion of tweets supporting legalization is slightly lower, with 48.26% (9162/19,024) in Europe and 47.21% (2335/4946) in Asia (Figure 3). $P<.001$ indicates statistical significance.

Figure 3. Percentage of tweets in favor of legalization. In dark blue are the countries where the most tweets in favor of cannabis legalization have been found, and as the blue gets lighter, the number of tweets decreases. In gray are the countries where there are no tweets in this category.

Discussion

Principal Findings

In this analysis conducted on the platform Twitter, 68.81% (142,139/206,529) of the tweets were geolocated. The study reveals that America is the continent with the most tweets about cannabis (112,004/206,529, 54.23%), followed by Europe (19,024/206,529, 9.21%) and Asia (4,946/206,529, 2.39%). Political discussion is the most common topic in America, Europe, and Asia, while personal testimonials dominate in Oceania and Africa. Across all continents, tweets about positive experiences with cannabis outnumber negative ones, with Oceania showing the highest percentage of positive experiences (1642/2695, 60.93%). Oceania also leads in support for cannabis legalization (1836/2695, 68.13%), followed by America (66,313/112,004, 59.21%) and Africa (1858/3470, 53.54%).

Currently, more than 40 countries have enacted laws allowing cannabis use for medicinal or recreational purposes, with significant legislative variability among them. Some countries permit both recreational and medicinal use, others allow only medicinal use, some have decriminalized possession and use for profit, while others maintain it as illegal [22]. The global debate on cannabis legalization is a multifaceted issue involving social, economic, medical, and legal aspects. Proponents of legalization argue that it allows for market regulation, which can lead to a reduction in criminal activity and associated costs, as well as positive economic impacts [23]. Arguments against cannabis legalization include its potential negative impact on public health [24], effects on the brain development of young people [25], and the potential increase in cases of driving under the influence of cannabis [26]. A study conducted in the United States to evaluate the impact of legalization found that it led to decreased prices and increased availability, which may have contributed to higher cannabis consumption among adults. In addition, there was an observed increase in emergency room visits and hospitalizations related to cannabis use [27]. A systematic review indicated that recreational legalization might be associated with an increase in traffic fatalities [28]. Furthermore, states in the United States where recreational cannabis use was legalized saw rises in self-harm and assault rates [29].

Among the 5 continents, America has the highest number of countries with both recreational and medicinal cannabis legalization, with a longer historical background, particularly in countries such as the United States and Canada. This is reflected in the high volume of tweets and the prevalence of political discussions, as these countries have been at the center of debates on legalization. The greater experience and acceptance of cannabis use in these countries may explain the high proportion of tweets with positive experiences. Regarding the perception of risk related to health and cannabis consumption, legalization has been found to not only increase consumption rates but also reduce the perception of harm and decrease treatment rates for cannabis use disorders [24]. A study conducted in the United States found that in states where medicinal use is legalized, there is a higher prevalence of daily use and cannabis use disorders [30].

Europe shows a greater inclination toward political discussion, reflecting the complexities and variations in legalization among its countries. The near parity in tweets both in favor of and against legalization in Europe suggests an active and diverse debate environment, with divided and evolving opinions. Indeed, during the time period covered by this study, no country had legalized recreational use, although countries such as the Netherlands and Portugal had decriminalized it and approved medicinal use. In addition, this debate aligns with the 3 proposed laws to legalize recreational cannabis use in Spain in 2021 [31].

As in Europe, the results reflect that there is also a debate about legalization in Asia. In this continent, the only country where recreational cannabis use was legalized in 2021 was Thailand. Therefore, research in this area is limited to this country, where an increase in cannabis consumption has also been observed following the policy changes associated with recreational cannabis use [32].

Finally, the high number of tweets about positive personal experiences found is concerning, as when a greater proportion of messages highlight positive experiences, the public is more likely to perceive consumption as safe or with fewer negative consequences [33]. Legalization may be influencing this perception. In a study conducted in California after the legalization of recreational cannabis use, the policy change was associated with perceptions of health benefits and cannabis consumption [34]. Similarly, in another study where an online survey was conducted with 16,000 Americans, it was observed that states where recreational cannabis use is legalized are more likely to believe in the benefits of marijuana [35]. The legalization of cannabis is a complex issue that involves not only medical aspects but also the need to convey to the public that its legalization does not make it less harmful. The effects of cannabis on health vary based on multiple factors such as the amount consumed, frequency of use, potency of the substance, and age, with younger individuals being the most susceptible [25]. Frequent cannabis use is associated with substance use disorders, such as those involving alcohol, tobacco, or cocaine [36], and poses a higher risk of developing depression [37] and suicidal behaviors [38,39]. A meta-analysis published in *JAMA Psychiatry* demonstrates that cannabis use during adolescence is associated with an increased risk of developing depression in adulthood and a higher risk of suicide [40,41]. Finally, cannabis use, especially in high doses or among individuals with a genetic predisposition, can increase the risk of developing psychotic disorders, such as schizophrenia [42]. Other substances, such as tobacco, while legal and socially accepted, are objectively harmful to health.

Limitations

This study has several limitations. First, the social, economic, and demographic characteristics of Twitter users do not accurately reflect the broader population. Users of this social network tend to be younger adults with higher education levels, and it is more popular in North America, Europe, and Asia. Second, the design of the coding book and the analysis of tweets involve some subjectivity, which is common in qualitative studies. However, this methodology is consistent with previous medical research studies. Third, certain colloquial terms for

XSL•FO
RenderX

cannabis, such as “dope” or “maría,” had to be excluded as keywords due to their multiple meanings, potentially resulting in lost sample data and information on the topic. Fourth, the opinions of Twitter users may vary over time, just as political debate topics do, so the conclusions of this study should be interpreted with caution. Fifth, another limitation is the difficulty of conducting an analysis based on the legal status of cannabis at a global level. In some countries, recreational cannabis use was legal before data collection began, while in others, it remained illegal until the end of the study period. Likewise, in the United States, legislation varies by state, and our database only identifies that the tweet originates from the country without specifying the state of origin. These legal differences introduce nuances that limit the validity of a comparative analysis. Finally, another limitation of this study is the potential variability in sampling and the availability of geolocated data on the Twitter platform. Twitter data is not always accurate or fully geocoded, which may affect the geographical representation of the results. Although geolocated information was used for some analyses, the lack of geolocation in many tweets may have influenced the observed distribution, limiting the ability to obtain an exact picture of the origin of the tweets. In addition, the limitation of using tweets published only in English or Spanish may explain why continents such as Africa or Asia are underrepresented. Future work should consider including more widely spoken languages in these continents.

Conclusions

The political debate has been the most frequently mentioned topic in relation to cannabis, reflecting the current situation in which legislative changes regarding cannabis are being discussed in many countries. On this social media platform, tweets in favor of legalization have predominated. Across all continents, positive experiences with cannabis have outweighed negative ones. These results suggest the need to incorporate information about the health risks associated with cannabis use, as it appears that these are being underestimated in the public debate.

Abstract

Background: Stillbirth, the loss of a fetus after the 20th week of pregnancy, affects about 1 in 160 deliveries in the United States and nearly 1 in 70 globally. It profoundly affects parents, often resulting in grief, depression, anxiety, and posttraumatic stress disorder, exacerbated by societal stigma and a lack of public awareness. However, no comprehensive analysis has explored social media discussions of stillbirth.

Objective: This study aimed to analyze stillbirth-related content on Instagram and X (formerly Twitter) by (1) identifying dominant themes using topic modeling, evaluated using latent Dirichlet allocation, non-negative matrix factorization (NMF), and BERTopic; (2) detecting influential hashtags via co-occurrence network analysis; (3) examining sentiments and emotions using transformer-based models; (4) categorizing visual representations of stillbirth on Instagram (Meta) through manual image analysis with a predefined codebook; and (5) screening for misinformation relating to stillbirth on X.

Methods: Stillbirth-related posts were collected via RapidAPI (N=27,395), with Instagram posts (#stillbirth: n=7415; #stillbirthawareness: n=8312; 2023 - 2024) and X posts (#stillbirth: n=11,668; 2020 - 2024) analyzed using Python 3.12.7 (Python Software Foundation), with NetworkX for hashtag co-occurrence networks and the PageRank algorithm; comparative analyses were restricted to 2023 - 2024 due to Instagram application programming interface constraints. Topic modeling was evaluated using latent Dirichlet allocation, NMF, and BERTopic, with coherence scores guiding our model selection. Sentiment and emotion were analyzed using transformer-based RoBERTa and DistilRoBERTa. Misinformation screening was applied to X posts. On Instagram, 2 representative image samples (n=366) were manually categorized using a predefined codebook, with the interrater reliability being assessed using Cohen Kappa.

Results: Health-related hashtags (eg, #COVID19) appeared more frequently on X. Topic modeling showed that NMF achieved the highest coherence scores (#stillbirthawareness=0.624 and #stillbirth=0.846 on Instagram, #stillbirth=0.816 on X). Medical misinformation appeared in 27.8% (149/536) of tweets linking COVID-19 vaccines to stillbirth. In the image analysis, “Image of text” was most common, followed by remembrance visuals (eg, gravesites and stillborn infants). The interrater reliability was strong, κ=0.837 (95% CI 0.773 - 0.891) and κ=0.821 (95% CI 0.755 - 0.879), with high Pearson correlation (r=0.999; P<.001) and no significant difference (χ^2_7=12.4; P=.09). The sentiment analysis found that positive sentiments exceeded negative sentiments. The emotion analysis showed that fear and sadness were dominant, with fear being more prevalent on X.

Conclusions: Instagram emphasizes emotional expression while X focuses on public health and informational content. Evidence-based communication is necessary to counter misinformation, especially on X, whose real-time affordances amplify fear-based narratives during crises, such as COVID-19. In addition, Instagram’s visual and commemorative content offers an opportunity to legitimize parental grief and to validate and humanize loss by directly involving bereaved parents in awareness campaigns. Platform-specific strategies and stronger moderation could enhance health discourse credibility. Future research should examine targeted approaches to counter misinformation and assist affected populations.

Introduction

Background

Stillbirth is defined as the delivery of a fetus that shows no signs of life at or after the 20th week of pregnancy [1]. Despite advances in medicine, about 2 million stillbirths occur every year worldwide [2]. Stillbirth occurs in approximately 1 in 160 deliveries in the United States [1] and nearly 1 in 70 globally [2]. Stillbirths may be caused by various factors, including placental abnormalities; infections; maternal health conditions, such as obesity, poorly controlled gestational diabetes mellitus, preeclampsia, and severe iron deficiency anemia; and inadequate prenatal care [1-4].

Experiencing a stillbirth can be an emotionally devastating event for parents, profoundly affecting their psychological well-being [5,6]. Studies have shown that parents who have experienced stillbirth are significantly more likely to experience a range of emotional and psychological challenges than those who have experienced a live birth. These challenges include symptoms of stress, depression, anxiety, social phobia, agoraphobia, anger, negative cognitive appraisals, such as feelings of failure and long-term guilt [7,8], and, in many cases, posttraumatic stress disorder [9-11].

After experiencing a stillbirth, parents face a deeply challenging and complex grief process [8,12], further exacerbated by several factors. One major issue is the lack of public awareness about stillbirth. The term itself is not widely known or understood, nor is its significant emotional impact on parents [13-15]. Another challenge is that stillbirth loss may not be recognized as a real death. Many stillborn babies are not formally named or buried, and parents may be unaware of the exact location of their child's burial [16-18]. This lack of recognition can complicate the grieving process, leaving parents feeling that their loss has been minimized or dismissed. Furthermore, the parents' grief can be amplified by societal stigma and blame, especially in cultures where stillbirth is taboo or reproduction is considered central to a woman's identity. In such settings, stillbirth may be unfairly viewed as a personal failure, adding an additional emotional burden to an already painful experience [18]. Compounding this, societal attitudes may fail to recognize the significance of the loss and grant it legitimacy, with some expecting parents to quickly continue with their lives and have another child [19].

Those perceptions leave parents feeling isolated, with disconnection from their social environment further deepening their sense of marginalization and loss of support [5]. A profound sense of isolation underscores the importance of supportive networks. Research indicates that women who experience strong family support report significantly lower levels of anxiety and depression than those who lack such support [20]. In addition, support groups have been found to significantly reduce posttraumatic stress responses in women who have experienced stillbirth [20].

Theoretical Framework

Continuing bonds theory posits that bereaved individuals maintain ongoing connections with the deceased, reframing grief as an adaptive process of sustaining attachments [21,22]. In digital spaces, this may manifest through digital memorialization and emotional expression, where social media enables shared narratives and visuals to preserve the deceased's presence [23]. For stillbirth grief, often disenfranchised, platforms like Instagram facilitate visual tributes that embody continuing bonds theory, while X (formerly Twitter) foregrounds public health discourse and supports spaces where grief is articulated and shared [24]. This study applies continuing bonds theory to analyze how these digital practices mitigate grief [21].

As part of the grieving process, bereaved parents navigating stillbirth confront a unique, often unseen form of loss [25]. Social media provides a space for digital memorialization, enabling ongoing connection with their baby's memory through shared narratives and visuals [21,26]. Grounded in continuing bonds theory, we hypothesize that Instagram's visual affordances and X's real-time discourse facilitate support and health discourses. Despite the presence of stillbirth content across digital platforms, existing studies are limited in scope. This study addresses this gap by systematically analyzing stillbirth content on social media, exploring themes, emotions, sentiments, misinformation, and visual representations.

Related Work

In this section, we review prior studies that have analyzed social media content relating to miscarriage, abortion, and stillbirth. In addition, we examine research relating to the spread of medical misinformation on social media platforms.

Miscarriage, Abortion, and Stillbirth on Social Media

Several studies have explored the representation of miscarriage and abortion in social media discourse. Miscarriage is defined as the spontaneous loss of a pregnancy before 20 weeks, while abortion refers to a medical procedure that terminates a pregnancy [27]. Cesare et al [28] conducted a large-scale analysis of 291,443 tweets posted between 2017 and 2018, focusing on miscarriage and preterm birth. Using latent Dirichlet allocation (LDA), the study identified thematic patterns within the textual data; however, it was limited to a single platform (X), excluded stillbirth-related content, and did not incorporate sentiment or emotional analysis. Similarly, Philippe et al [29] examined tweets on X to assess public opinions and sentiment surrounding miscarriage and abortion. Their study concentrated on engagement metrics but did not include stillbirth in its scope of analysis.

Additional studies addressing pregnancy loss on social media have primarily focused on miscarriage and been based on limited, small sample sizes. For instance, Mercier et al [30] analyzed 200 Instagram posts tagged with #ihadamiscarriage. Similarly, Callen and Oxlad [31] used content analysis to examine 270 posts and 3484 comments within a closed Facebook (Meta) support group dedicated to miscarriage.

Stillbirth is clinically distinct from miscarriage, as it occurs at or after 20 weeks of gestation and typically involves full labor—and in some cases, may even require a cesarean section [32,33]. This combination of physical demands and the psychological trauma of delivering a nonviable infant makes stillbirth a uniquely complex and emotionally challenging

XSL•FO
RenderX

experience. However, despite its profound impact, stillbirth remains significantly underrepresented in social media research. The limited number of studies that have directly examined stillbirth-related content on social media is narrow in both design and scope, often lacking in methodological depth, multimodal analysis, or large-scale data coverage. For example, Sani et al [34] and Geusens et al [35] analyzed small samples of YouTube videos (50 and 19, respectively) using qualitative methods to explore themes, such as grief, rituals, and parental experiences. Chan et al [36] assessed the reach of a public health campaign ("Still Six Lives") through social media metrics and surveys. However, these studies did not use computational methods, lacked sentiment and emotion analyses, and were restricted to a single platform.

This study seeks to address this gap by presenting the first large-scale, cross-platform, and multimethod analysis of stillbirth-related discourse on social media, focusing on X and Instagram. These 2 platforms are more suited for stillbirth content analysis than other platforms, such as Facebook. Instagram's visual focus enables a thorough analysis of grief and remembrance through images [30]. X's real-time, public nature facilitates the tracking of emotional expressions and themes [37]. Facebook's more private, network-based structure generally yields less accessible and diverse public discourse on such sensitive topics than the platforms of Instagram and X [38]. Specifically, this study integrates topic modeling, sentiment and emotion detection, identification of medical misinformation, hashtag network analysis, temporal trend analysis, and manual coding of visual content across both platforms. Together, these analyses provide a more comprehensive understanding of how stillbirth is discussed, visualized, and represented within the digital public sphere.

Misinformation on Social Media

Medical misinformation on social media has been widely explored in recent research [39,40]. For instance, several studies have used automated misinformation detection techniques, including the use of deep learning models, to identify and classify false or misleading health-related content across various platforms [41,42].

During the COVID-19 pandemic, the prevalence and impact of health-related misinformation increased dramatically, particularly regarding vaccines. Of concern, a meta-analysis among vaccinated individuals found no safety concerns for COVID-19 vaccination during pregnancy [43]. Moreover, a systematic review and meta-analysis found that COVID-19 vaccination was associated with a lower risk of stillbirth [44]. Nevertheless, claims linking COVID-19 vaccines to infertility, miscarriage, and stillbirth without any basis in scientific evidence were circulated widely on platforms, such as Facebook, Instagram, TikTok, and X, shaping public discourse and fueling vaccine hesitancy [45]. This prompted a surge of research focusing on the dynamics and consequences of vaccine-related misinformation in digital environments. However, studies that specifically examine the intersection of stillbirth and misinformation on social media remain limited.

Methods

Software

All data analyses and visualizations were performed using Python version 3.12.7 (Python Software Foundation).

Data Collection

Posts were collected from the social media platforms Instagram and X, both of which were purposefully selected for their distinct roles in shaping social media discourse. Instagram, as a visually driven platform, facilitates personal storytelling and emotional expression, primarily through images and stories [46,47]. This makes it particularly well-suited for capturing the visual and affective dimensions of stillbirth experiences. In contrast, X is a predominantly text-based medium that functions as a dynamic arena for public debate [48] and the rapid dissemination of health-related information [49]. Together, these platforms support a comprehensive exploration of the diverse narratives, emotional expressions, and visual practices of stillbirth discourse in the digital public sphere.

The data for this study were obtained using the RapidAPI platform, which provides access to social media content through an application programming interface (API). We collected all available data provided by the API. For Instagram, we retrieved posts containing the 2 most used hashtags relating to stillbirth: #stillbirth and #stillbirthawareness. These posts were collected between January 1, 2023, and February 20, 2024, and included the publication date, accompanying text, and associated image. For X, we collected all available posts associated with the hashtag #stillbirth. X data were collected between January 1, 2020, and December 31, 2024, and included the tweet ID, publication date, and text.

We acknowledge the temporal mismatch between the 2 datasets. While the X data spans 5 years (2020 - 2024), Instagram data is limited to the 2023 - 2024 period. This discrepancy results from technical limitations in Instagram's API at the time of data collection in 2024, which restricted our access to recent content only. This divergence introduces a potential methodological limitation, particularly for comparative analyses. To address this, any cross-platform comparisons were limited to the overlapping time frame of 2023 - 2024. However, in analyses that focused solely on X, the full dataset (2020 - 2024) was used to provide a broader temporal context.

Hashtag Co-Occurrence Network

As mentioned in the "Data Collection" section, our dataset comprised 3 subsets of data based on posts containing the hashtags #stillbirth (on both X and Instagram, forming 2 subsets) and #stillbirthawareness (1 subset on Instagram). Since individual posts often included additional hashtags beyond those used for initial retrieval, we conducted a hashtag co-occurrence network analysis to explore how hashtags clustered and co-occurred within posts.

Two hashtag co-occurrence networks were constructed: one based on posts containing #stillbirth on X, and the other from Instagram posts featuring the same hashtag. To ensure

XSL•FO
RenderX

comparability between platforms, the analysis was restricted to a consistent time frame spanning the years 2023 - 2024.

In each network, each node represents a hashtag, and an edge connects 2 hashtags if they appear together in the same post. The network is undirected, and the weight of each edge is determined by the number of posts in which hashtags co-occurred.

For each network, PageRank scores were calculated to identify the most influential hashtags. PageRank is an algorithm developed by Google's founders to rank web pages based on their importance within a network [50]. It assigns higher scores to nodes that are connected to several other important nodes. The PageRank algorithm is widely used in network analysis as a centrality measure [51].

For a hashtag's co-occurrence network, PageRank helps identify the most prominent hashtags by analyzing their connections, where the importance of a hashtag is determined based on its frequent co-occurrence with other hashtags. For each network, we analyzed the nodes with the highest PageRank scores in order to identify the most influential hashtags within the discourse. This centrality-based approach provided deeper insights into the hashtags shaping discussions on social media about stillbirth.

The PageRank calculation was performed with its default parameters using the NetworkX library in Python. To enable a meaningful comparison of the prominence of hashtags across Instagram and X, we addressed the challenge that PageRank scores are inherently platform-specific due to differences in network structures and co-occurrence patterns [52]. As such, a direct comparison of absolute PageRank values across platforms may be misleading. To overcome this limitation, we used 2 complementary strategies: First, we ranked all hashtags within each platform according to their PageRank scores. This approach allowed us to identify the most influential hashtags within each network based on their internal structure and relative centrality.

Second, we calculated a normalized relative weight for each hashtag. This was defined as the sum of the hashtag's edge weights across all co-occurrence connections, divided by the total sum of edge weights in the respective platform's network. This normalization enabled a more reliable and consistent comparison of different hashtags' prominence across platforms.

It is important to note that it was not possible to statistically assess whether the difference in relative weight for each individual hashtag across platforms was significant, as each hashtag is represented by a single data point per platform. In the absence of multiple observations per hashtag, standard significance testing could not be applied.

Finally, to visually explore the hashtag co-occurrence structure, we constructed network graphs for both platforms (X and Instagram) using Cosmograph (Nikita Rokotyan) [53]. Cosmograph is a browser-based tool designed for the visualization of large-scale network graphs and machine learning embeddings. In this study, we used the tool with its default settings. In each network, hashtags are shown as nodes, with size, color, and label color reflecting PageRank centrality, and edges weighted by hashtag co-occurrence frequency.

Topic Modeling

To explore the dominant narratives surrounding stillbirth on social media, we applied topic modeling to categorize posts into distinct thematic clusters. This analysis was conducted separately for 3 subsets. Of these, 2 subsets of posts containing the hashtag #stillbirth on both X and Instagram, and 1 subset of posts that were tagged with #stillbirthawareness on Instagram. All hashtags were removed from the input prior to modeling. This decision was made to avoid redundancy, as hashtags were already analyzed in the hashtag co-occurrence networks. By focusing exclusively on the textual body of the posts, the topic modeling aimed to capture the narrative content, without any influence from metadata or tag-based categorization.

Since the goal of this analysis was to identify prevalent topics on social media in the context of stillbirths, we did not restrict the datasets to the same time period across platforms. Instead, the analysis was conducted using the full range of available data from each platform. As such, the results should not be interpreted as a direct comparison between platforms.

Prior to the topic modeling, we implemented a text preprocessing pipeline. Each post was first converted to lowercase, and all nonalphabetic characters, redundant whitespace, and platform-specific artifacts ("amp," "com," "www," "https") were removed. URLs and hashtags were stripped. Tokenization and lemmatization were performed using the English-language SpaCy model (en_core_web_sm). During this process, only alphabetic tokens were retained, and standard English stop words, as defined by the Natural Language Toolkit corpus, were excluded.

To determine the most effective method for topic extraction, we systematically compared three topic modeling algorithms:

1. BERTopic: A neural topic modeling approach that leverages transformer-based document embeddings, density-based clustering, and class-based Term Frequency–Inverse Document Frequency (TF-IDF) to generate coherent topic representations [54].
2. LDA: A probabilistic generative model that assumes that documents are mixtures of latent topics, where each topic is characterized by a distribution over words and each document is represented as a distribution over topics [55].
3. Non-negative matrix factorization (NMF): A matrix decomposition method that factorizes the document-term matrix into 2 non-negative matrices representing topic-word and document-topic associations [56].

Each algorithm was applied separately to the dataset using its default parameters. For LDA and NMF, the preprocessed text was vectorized using CountVectorizer class from the scikit-learn library, and the vocabulary was restricted to the 1000 terms with the highest document frequency across the corpus. The resulting document-term matrix was weighted using TF-IDF. For these models, we varied the number of topics from 2 to 70 and computed the average coherence score (c_v) [57] to evaluate the topic quality. This metric assesses the semantic similarity among the top terms within each topic, providing an estimate of the conceptual coherence. In contrast, BERTopic

XSL•FO
RenderX

automatically determined the number of topics using density-based clustering.

For each social media platform and hashtag subset, we selected the algorithm and number of topics that yielded the highest coherence score. This ensured that both the modeling approach and the number of topics reflected the most coherent and meaningful segmentation of the data. To label the topics, we extracted the top 15 most representative terms based on their TF-IDF weights from the topic–word matrix. These key terms, in combination with representative post examples, informed the assignment of descriptive topic labels.

Misinformation Analysis

To identify and assess the prevalence of posts, including misinformation on COVID-19 vaccination and stillbirth, we screened all tweets on X. Instagram was not part of this analysis due to its shorter data collection window and the absence of relevant cases containing medical misinformation on this topic during the sampled period. The detailed screening process is illustrated in Figure 1 and will be further elaborated in the "Results" section of the misinformation analysis. Tweets were initially screened based on the presence of the term "stillbirth." From this set, tweets relating to vaccination or COVID-19 were selected by identifying any variation of the terms "covid," "vaccin," or "vax" ("vaccin" was used as a stem to capture variations such as vaccine, vaccines, vaccination, and vaccinated, while "vax" is a common informal abbreviation of "vaccine" [58]). Tweets containing these terms solely in irrelevant contexts, such as within URLs, were manually withdrawn. All remaining tweets were manually reviewed by a medical expert specializing in stillbirth and maternal health, with over 10 years of research experience in pregnant women and more than 6 years of clinical practice and responsibility for research and development in the Department of Obstetrics and Gynecology at a hospital in Israel.

XSL•FO
RenderX

Figure 1. Flowchart of source data generation regarding misinformation on COVID-19 vaccination and stillbirth (2020-2024).

XSL•FO
RenderX

Misinformation screening was informed by established misinformation detection frameworks, including World Health Organization (WHO) Guidelines [59] and peer-reviewed scientific evidence [44-46]. Misinformation was defined as content containing claims that contradicted the WHO's guidelines and peer-reviewed scientific evidence, or that cited noncredible or disproven sources. Ambiguous cases were resolved through discussion with a second reviewer until consensus was reached. Examples of tweets classified as misinformation are provided in the "Results" section.

Sentiment and Emotion Analyses

Overview

For each post, we analyzed both the emotions and sentiments expressed in the text. Emotion analysis identifies specific feelings, such as sadness and joy, while sentiment analysis categorizes the overall tone of a sample as positive, negative, or neutral. This was undertaken to understand the range of emotions associated with stillbirths across Instagram and X.

Sentiment Analysis

The sentiment analysis (positive, negative, and neutral) was performed using Twitter-roBERTa-base for Sentiment Analysis [60], a RoBERTa-base model that was pretrained on approximately 124 million tweets collected between January 2018 and December 2021. The model was fine-tuned specifically for sentiment analysis using the TweetEval benchmark, ensuring high accuracy and relevance for analyzing social media text.

Emotion Analysis

The emotion analysis (anger, disgust, fear, joy, neutrality, sadness, and surprise) was conducted using the Emotion English DistilRoBERTa-base model [61]. This model is a fine-tuned checkpoint of DistilRoBERTa-base, designed to classify emotions in English text data. The model was trained on 6 diverse datasets, consisting of a balanced subset of nearly 20,000 observations (2811 observations per emotion). Of this subset, 80% (16,000/20,000) was used for training and 20% (4000/20,000) for evaluation, achieving an evaluation accuracy of 0.66.

To enable a fair comparison between Instagram and X in both sentiment and emotion analysis, we restricted the cross-platform analysis to posts collected during the overlapping time frame of 2023 - 2024. For each platform, we calculated CIs for the proportion of posts that were classified under each sentiment and emotion category using Wilson score CIs [62]. CIs were computed at the 95% confidence interval. The Wilson method was chosen for its ability to provide more reliable estimates of the true underlying proportions, as it accounts for both the sample size and observed proportion [63].

In addition, since the dataset from X covered a broader date range (2020 - 2024), sentiment and emotion scores are presented as aggregated by year, allowing for the identification of temporal trends in public emotional responses.

Image Analysis

Overview

Sample Size Calculation

To determine the required sample size for statistical representativeness, we applied the standard sample size formula for finite populations [64]. The calculation was based on a total population of Instagram posts tagged with #stillbirth, using a 95% CI and a ±5% margin of error.

Random Sampling

To support both category development and classification reliability, 3 distinct random samples of images were drawn from the full dataset. The sample size for each was based on the calculation described in phase 1, ensuring statistical representativeness. The first sample was used to develop the category codebook, while the remaining 2 were independently analyzed for image classification. Using 2 classification samples enabled us to assess the stability of category distributions across different subsets and reduce the risk of sampling or selection bias.

Development of the Category Codebook

The first sample from phase 2 of the initial Instagram images was manually open-coded, allowing for recurring visual motifs and semantic themes. Overlapping codes were then merged, and discrepancies were resolved through discussion among the research team. This iterative process led to the creation of a structured codebook consisting of 8 specific categories, organized under 4 overarching themes: graphic expressions, parenthood, remembrance, and others.

Table 1 presents the finalized codebook, outlining the main categories, subcategories, operational definitions, and representative examples that guided the classification of Instagram images tagged with #stillbirth.

XSL•FO
RenderX

Table . Codebook for visual content categories in stillbirth-related Instagram posts.

Main category	Subcategory	Description	Examples
Graphic expressions	Image of text	Images in which the primary content is written text	Quotes, facts, and supportive statements
Graphic expressions	Illustrations	Artistic visuals created either digitally or by hand	Drawings, paintings, and graphic designs
Parenthood	Family moments	Personal images depicting shared family interactions, celebrations, or milestones	Family gatherings, holiday celebrations, birthday parties, siblings, and "rainbow babies" (infants born after a stillbirth)
Parenthood	Motherhood	Images depicting a mother or woman	Selfies of the mother, mother holding a baby
Remembrance	Stillborn infant	Photographs of stillborn babies	The baby in a hospital setting, being held by parents, partial views (eg, head, hand, and foot)
Remembrance	Memorial tributes	Images created to honor and remember the baby	Gravesites, remembrance candles, memory boxes, and baby footprint
Remembrance	Pregnancy	Visuals honoring a pregnancy that ended in loss	Ultrasound images, pregnancy tests, and gestational images
Other	None	Images unrelated to the core thematic categories	Food, fashion, fitness, or general lifestyle content

Annotator Training and Manual Classification

Two independent annotators (research assistants) were involved in the manual classification process. They participated in a 1-hour calibration session using the images used in the development of the codebook. During this session, ambiguous cases were reviewed, and coding definitions were refined to ensure consistent interpretation. Following training, both annotators independently classified each image in the 2 study samples using the codebook. Disagreements were resolved through collaborative discussion; when a consensus could not be reached, a third reviewer adjudicated the final label.

Interrater Reliability Assessment

The interrater reliability between annotators was assessed using Cohen Kappa statistic to evaluate the level of agreement beyond chance [65]. To estimate the uncertainty around the Kappa value, a nonparametric bootstrap method with 1000 resamples was applied [66]. The resulting distribution was used to derive a 95% CI for the Kappa estimate.

Cross-Sample Consistency Check

To verify that the 2 independent image classification runs yielded statistically comparable category distributions, a Pearson correlation was computed between the raw category counts from each sample [67]. In addition, a chi-square goodness-of-fit test was conducted to assess whether the observed frequencies deviated significantly from the expected values [68].

Ethical Considerations

The data collection process and analysis were approved by the Emek Yezreel College Ethical Review Board (approval number 2024 - 136 YVC EMEK). As the research relied solely on publicly available social media data and did not involve direct interactions with individuals, informed consent was not applicable. No compensation was offered or provided, as the study did not involve the direct participation of human participants. All data used in the analysis were publicly available and did not contain personally identifiable information.

Results

Data Collection

On X, we collected posts containing the hashtag #stillbirth, while on Instagram, we retrieved posts tagged with both #stillbirth and #stillbirthawareness. A total of 27,395 posts were collected across platforms based on the volume of data that was accessible via the respective APIs, including 7,415 Instagram posts with the hashtag #stillbirth (2023–2024), 8,312 Instagram posts with the hashtag #stillbirthawareness (2023–2024), and 11,668 posts on X with the hashtag #stillbirth (2020–2024).

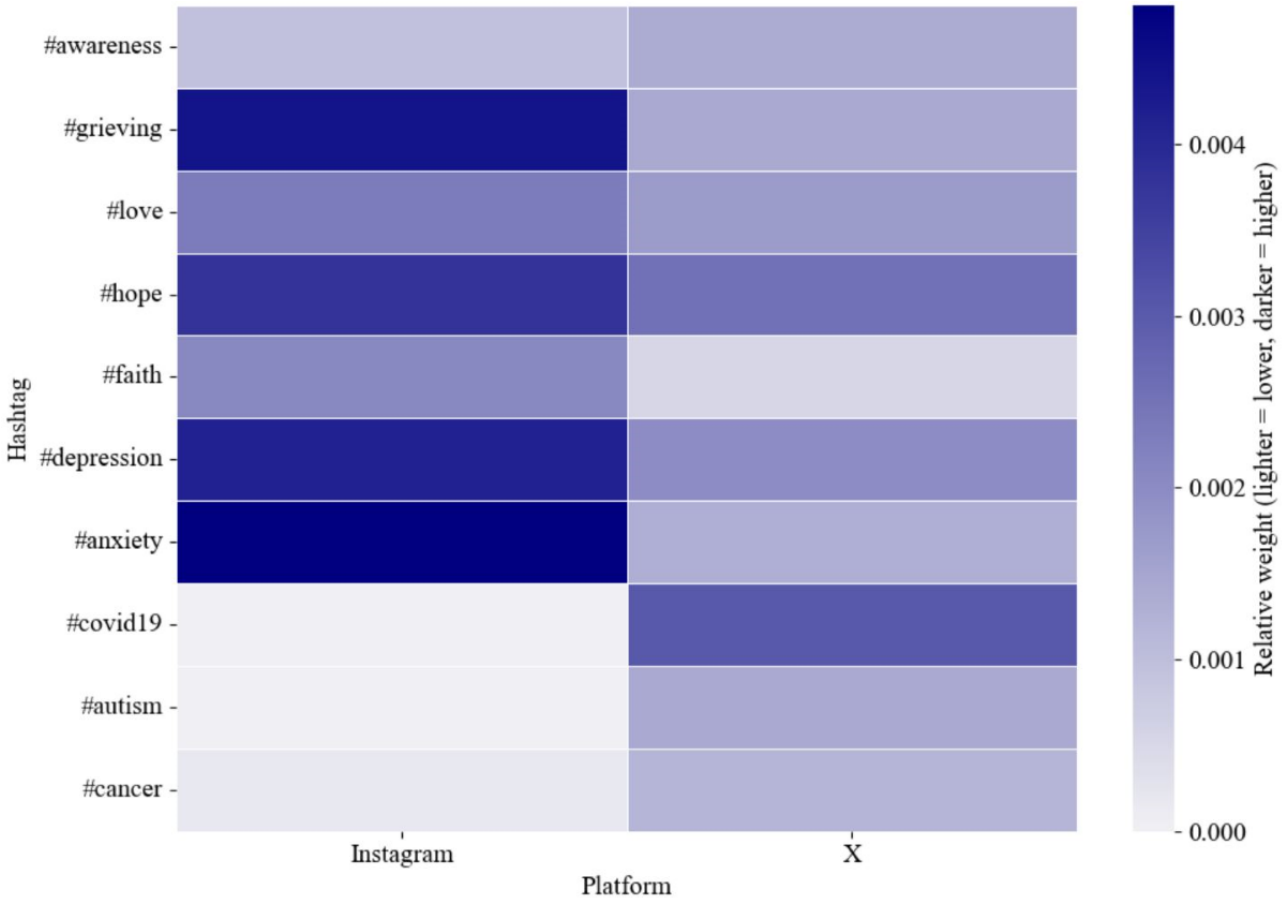
Multimedia Appendix 1 displays the annual distribution of posts retrieved from Instagram and X. Due to API limitations, the Instagram dataset primarily covers the 2 years preceding data collection (2023 - 2024). Therefore, a longitudinal analysis was not feasible for Instagram. In contrast, the X dataset spans a broader period with a relatively consistent volume of tweets from 2020 to 2024, enabling temporal analysis.

Hashtag Co-Occurrence Networks

We constructed 2 separate hashtag co-occurrence networks based on the datasets from the years 2023 - 2024. The first network, derived from Instagram posts containing #stillbirth, consists of 10,936 unique hashtags (nodes) and 225,912 connections (edges). The second network, built from tweets on X that contain #stillbirth, contains 3854 unique hashtags and 22,295 edges.

Multimedia Appendix 2 provides a complete list of all hashtags from both X and Instagram, along with their corresponding PageRank scores. The primary hashtag (#stillbirth) that was

XSL•FO
RenderX



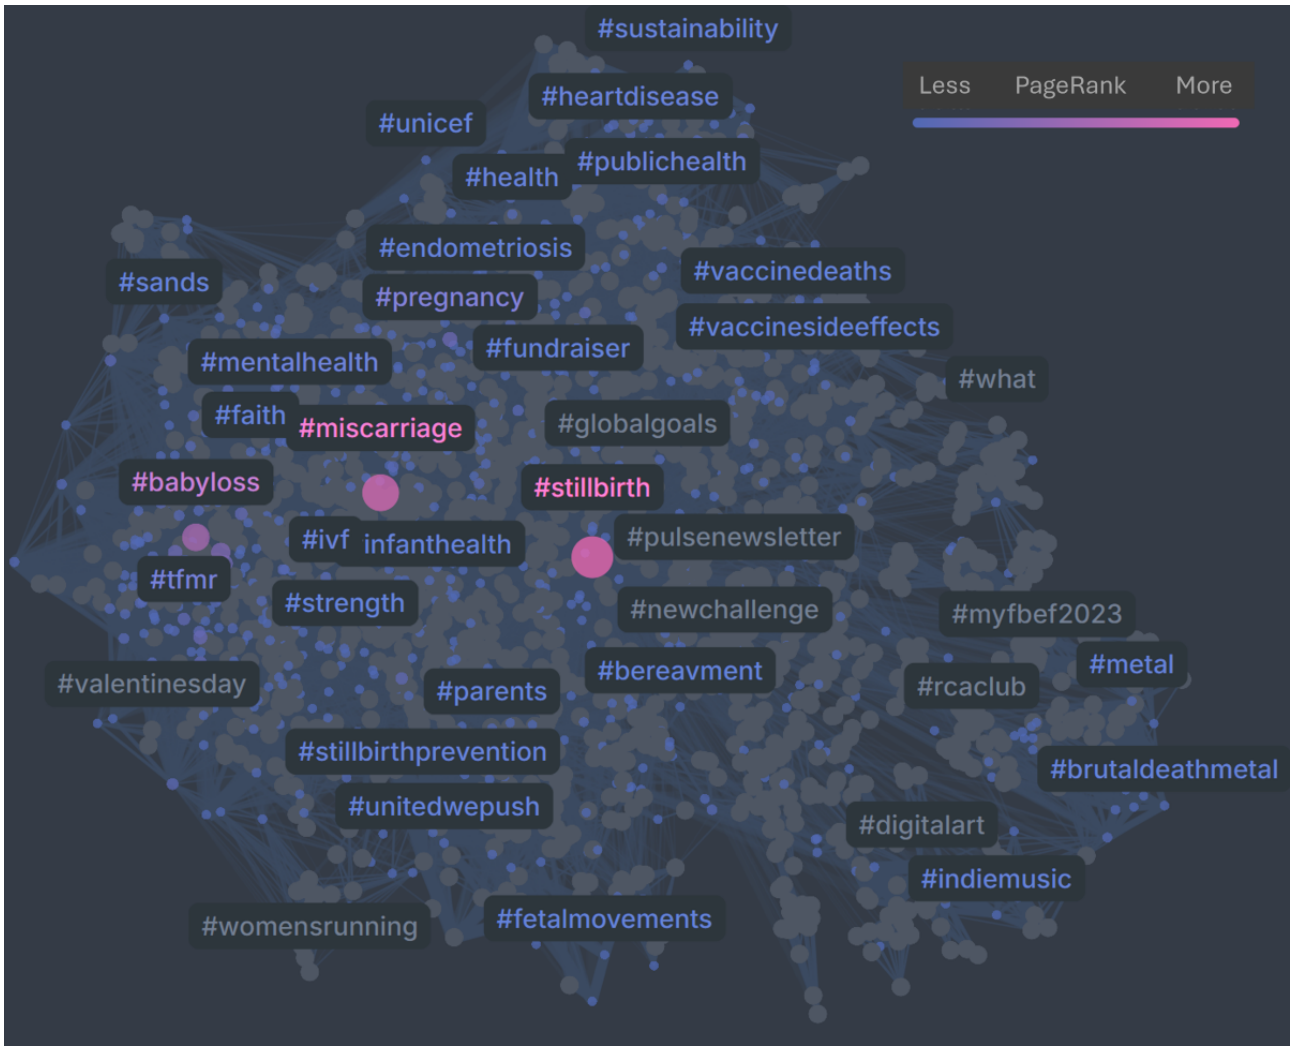
used to collect the data was excluded from the ranking, as expected, since it was central to the dataset. Across both platforms, hashtags, such as #miscarriage, #pregnancyloss, #babyloss, #infantloss, and #grief consistently appear at the top, reinforcing their strong connection to stillbirth-related discussions.

The hashtags can be categorized into distinct themes:

1. Loss-related hashtags: These directly reference different types of pregnancy and infant loss, including #pregnancyloss, #pregnancyandinfantloss, #babyloss, #tfmr (termination for medical reasons), and #infantloss.
2. Emotional expression hashtags: The tags, such as #grief and #stillbornstillloved, convey personal emotions and mourning.
3. Awareness-related hashtags: These highlight efforts to raise awareness about stillbirth and related issues, including #babylossawareness, #neonataldeath, #pregnancylossawareness, #miscarriageawareness, and #infantlossawareness.
4. Support-related hashtags: These hashtags are used to foster community support and connection, and they include #babylosscommunity, #griefsupport, #miscarriagesupport, #stillbirthsupport, and #babylosssupport.
5. Encouragement-related hashtags: These provide emotional encouragement and acknowledgment for bereaved families, including hashtags, such as #bereavedparents, #bereavedmother, and #rainbowbaby (which refers to a live baby being born after a pregnancy loss, symbolizing hope after grief).
6. Health-related hashtags: Among the top 30 hashtags on X, several are linked to medical topics, including #COVID19. A further examination of tweets relating to COVID-19 is described in the misinformation analysis section.

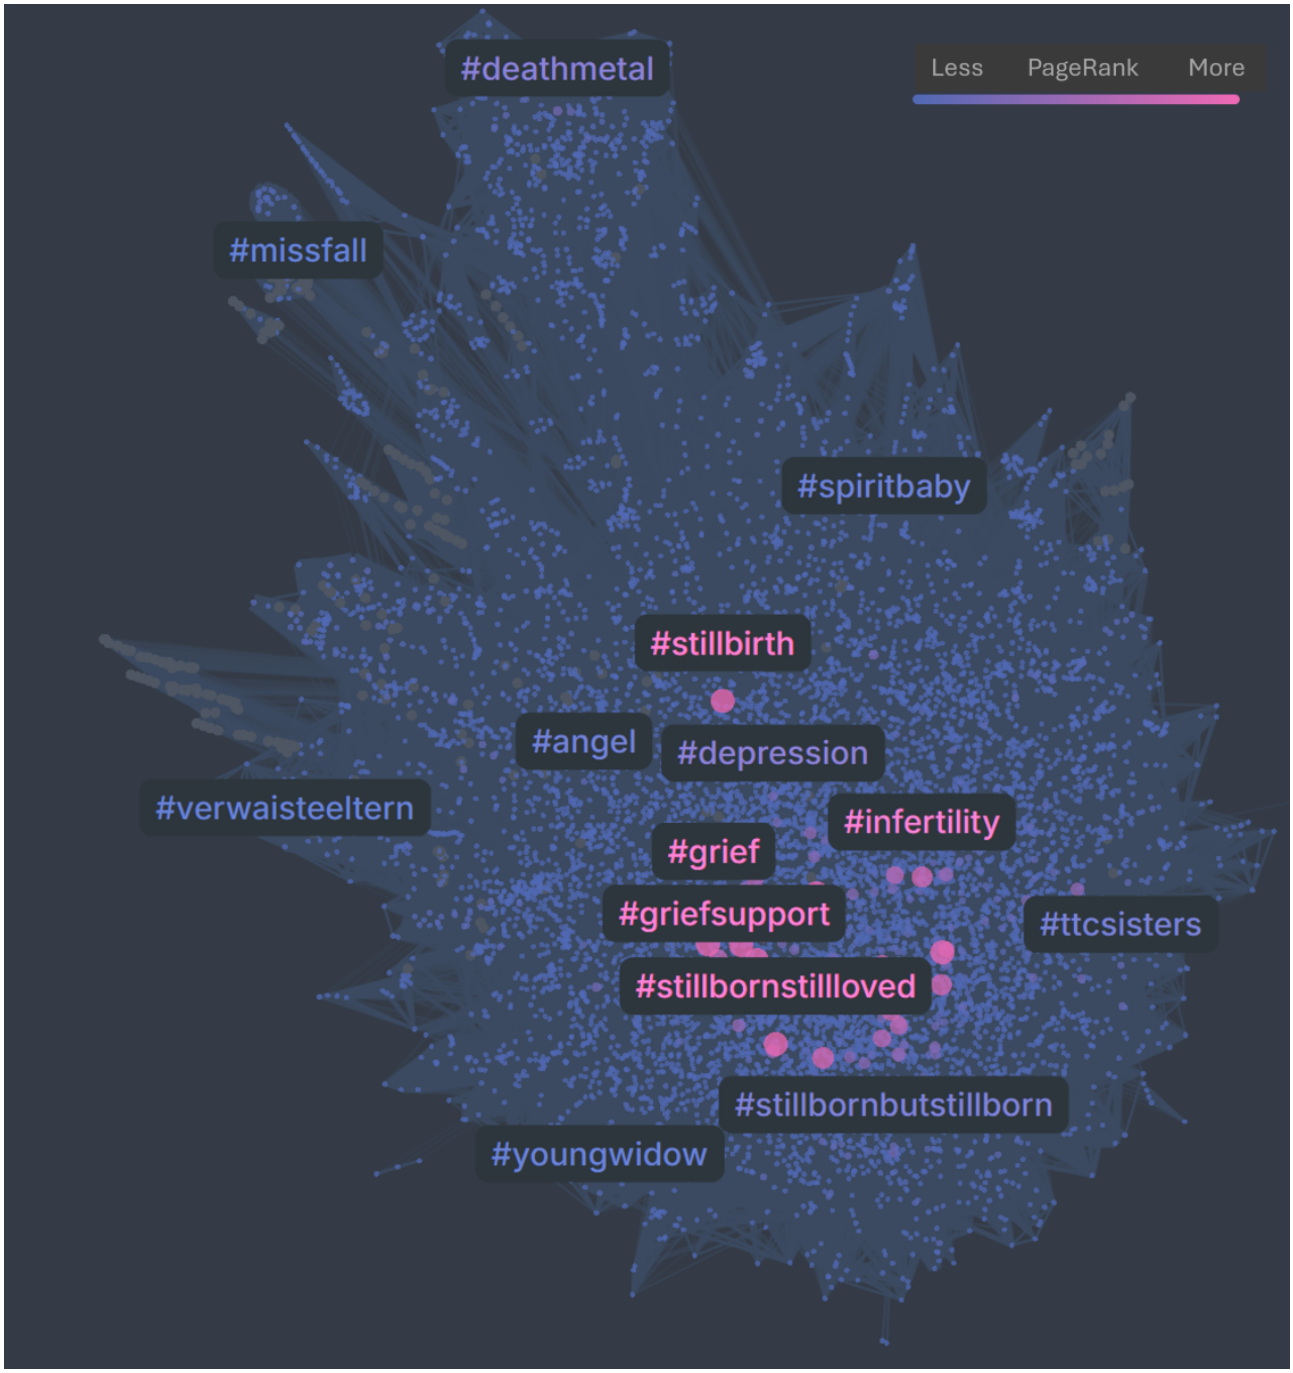
Figure 2 presents a comparison of selected hashtags relating to emotional and health themes across Instagram and X, based on their relative weights within each platform's hashtag co-occurrence network. Multimedia Appendix 2 also provides the full list of hashtags and their corresponding relative weights. Darker shades in the figure indicate a higher relative prominence of a hashtag on the given platform. The results show that hashtags such as #anxiety, #depression, and #grieving appear with greater relative weight on Instagram, suggesting a stronger emphasis on emotional expression and mental health within that platform. In contrast, hashtags such as #COVID19, #autism, and #cancer are relatively more prominent on X, possibly reflecting more informational or public health-oriented discourse. Hashtags such as #hope, #love, and #faith exhibited slightly higher relative weights on Instagram than on X.

Figure 2. Comparison of selected hashtags across Instagram and X (2023 - 2024) based on their relative weights.



Figures 3 and 4 present the hashtag co-occurrence networks for #stillbirth on X and Instagram, respectively, for the period 2023 - 2024. In both networks, nodes represent hashtags, with node size, node color, and hashtag label color corresponding to PageRank scores, and edges weighted by the frequency of hashtag co-occurrence. The X network (Figure 3) positions

XSL•FO
RenderX



#stillbirth within a broader and more heterogeneous structure, linking to bereavement-related hashtags (eg, #miscarriage, #babyloss, and #mentalhealth) alongside peripheral connections to broader health topics, such as vaccinations. In contrast, the Instagram network (Figure 4) forms a denser and more cohesive cluster centered on emotional support and bereavement, reflecting a concentrated community focus on personal loss.

Figure 3. Hashtag co-occurrence network for #stillbirth on X (2023 - 2024).

XSL•FO
RenderX

Figure 4. Hashtag co-occurrence network for #stillbirth on Instagram (2023 - 2024).

Topic Modeling

To identify the dominant narratives surrounding stillbirth on social media, we applied and evaluated 3 topic modeling algorithms, such as LDA, NMF, and BERTopic. Table 2 presents the top 3 configurations for each dataset—X posts tagged with #stillbirth, Instagram posts tagged with #stillbirth, and Instagram posts tagged with #stillbirthawareness—ranked by their coherence scores. These results highlight the most effective combinations of algorithm and topic count for capturing coherent themes. Multimedia Appendix 3 presents the full results of the topic modeling evaluation process, conducted across the 3 algorithms, for each social media platform and hashtag.

XSL•FO
RenderX

Table . Top 3 topic modeling results per hashtag and platform, sorted by their coherence scores; the selected result for each hashtag–platform combination is highlighted in bold.

Social media	Hashtag	Algorithm	Number of topics	Coherence score
Instagram	#stillbirthawareness	BERTopic	68	0.639
Instagram	#stillbirthawareness	BERTopic after reducing outliers	68	0.602
Instagram	#stillbirthawareness	NMF[a]	3	0.629[b]
Instagram	#stillbirthawareness	NMF	4	0.624
Instagram	#stillbirth	NMF	4	0.846[b]
Instagram	#stillbirth	NMF	5	0.821
Instagram	#stillbirth	NMF	3	0.821
X	#stillbirth	NMF	4	0.816[b]
X	#stillbirth	NMF	3	0.813
X	#stillbirth	BERTopic	105	0.813

[a]NMF: Non-negative matrix factorization.

[b]Selected result for each hashtag–platform combination.

In Instagram posts tagged with #stillbirthawareness, the BERTopic model initially achieved the highest coherence score (0.639), with 68 topics. However, the model classified 4230/8312 posts as posts that could not be assigned to any topic, indicating a substantial proportion of outliers that were not grouped into meaningful clusters. This suggests that despite its high coherence, the model may have struggled to capture thematic consistency across a large portion of the dataset. To address this, we applied BERTopic's built-in outlier reduction method, which reassigns unclustered posts to the most semantically similar existing topics based on their embeddings. This adjustment reduced the number of outliers to only 10, thereby improving the topic coverage and interpretability. However, this came at the cost of a lower coherence score (0.602). Given this trade-off, we selected the configuration that achieved the highest coherence score, which was produced by NMF with 3 topics (coherence=0.629), for the final analysis.

For the Instagram dataset tagged with #stillbirth, the best results were obtained using the NMF algorithm with 4 topics, yielding a coherence score of 0.846. Similarly, for the X dataset tagged with #stillbirth, the highest coherence score (0.816) was also achieved using the NMF algorithm configured with 4 topics.

Table 3 presents the topics that were extracted using the topic modeling of social media posts across Instagram and X containing the hashtags #stillbirth and #stillbirthawareness. For each topic, the topic name and number of associated posts are provided.

Table . Topics identified through topic modeling for #stillbirthawareness and #stillbirth on Instagram and #stillbirth on X, including topic name and count.

Social media platform	Hashtag	Topic number	Topic name	Post count
X	#stillbirth	1	Awareness and remembrance	5655
X	#stillbirth	2	Support	2946
X	#stillbirth	3	Risks, prevention, and research	2390
X	#stillbirth	4	Inspiring stories	677
Instagram	#stillbirth	1	Remembering and honoring lost babies	3989
Instagram	#stillbirth	2	Support	2734
Instagram	#stillbirth	3	Natural remedies and healing	225
Instagram	#stillbirthawareness	1	Remembering and honoring lost babies	4315
Instagram	#stillbirthawareness	2	Awareness and remembrance	1590
Instagram	#stillbirthawareness	3	Support and prevention	2407

XSL•FO
RenderX

For X posts with the hashtag #stillbirth, the most dominant topic, with 5655 posts, was "Awareness and remembrance," reflecting deeply emotional language around loss, love, and awareness of stillbirth experiences. The second most common theme, "Support" (2946 posts), centered on expressions of gratitude and requests for help, emphasizing a need for practical and emotional support. The third topic, "Risks, prevention, and research", included 2390 posts and focused on calls to action, policy discussions, and education about prevention. Finally, "Inspiring stories", although smaller in volume (677 posts), captured narratives of personal stories, faith, and resilience.

For Instagram posts under the hashtag #stillbirth, we excluded 1 topic containing 467 posts in different languages from the table. "Remembering and honoring lost babies" (3989 posts) was the most prevalent topic, emphasizing sentiments of love and grief and often referring to significant dates, such as birthdays or anniversaries of the baby's death. The second topic of support (2734 posts) consisted mostly of texts providing guidance and assistance for families coping with stillbirth. Many of these posts focused on offering emotional support, sharing helpful resources, and raising awareness about available services for grieving parents. A smaller topic, "Natural remedies and healing" (225 posts), featured advertisements for natural products and alternative healing methods.

For #stillbirthawareness on Instagram, the theme of "Remembering and honoring lost babies" was the dominant topic (4315 posts), reflecting personal expressions of grief, love, and remembrance. The "Awareness and remembrance" category (1590 posts) contained discussions surrounding stillbirth awareness and remembrance initiatives, with notable mentions of October, which is internationally recognized as Pregnancy and Infant Loss Awareness Month. The "Support and prevention" category (2407 posts) focused on providing help and guidance for families, advocating for stillbirth prevention efforts, and sharing information from organizations.

Misinformation Analysis

As shown in Figure 1, out of the tweets containing the term "stillbirth" and additional references to "covid," "vaccin," or "vax," a total of 536 tweets were manually analyzed. Following classification, 27.8% (149/536) were identified as containing medical misinformation relating to stillbirth and vaccination.

These tweets frequently included unsubstantiated claims suggesting causal links between COVID-19 vaccination and adverse pregnancy outcomes, such as miscarriage or stillbirth. Many relied on anecdotal evidence that was presented through unofficial websites or films, expressed distrust in public health authorities, and amplified conspiracy theories portraying vaccines as harmful, poisonous, or intentionally designed to cause widespread harm or even genocide.

Examples include the following:

1. "i wouldnt be taking vaccine look up #stillbirth"
2. "#vaccineinjuries #vaccinegenocide #vaers #vaccine #vaccines #suddendeaths #fertility #miscarriage #suddendeath #diedsuddenly #stillbirth #depopulationagenda #depopulation #fda"
3. "Why are there so many stillbirths and pregnancy issues with vaccinated women? #mrna #ace2 #stillbirth #miscarriage #phizer #vaccineinjuries #crimesagainsthumanity"
4. "Just watched a film!!! I knew the #vaccines weren't safe, but to see all the embalmers describing the clots, the #stillbirth data, and the military #whistleblowers was just shocking!"
5. "Please stop telling #women to take these #vaccines, it's killing their #babies!!! If you can't do that then stop practicing medicine!! #miscarriages #stillbirth #vaers"

Sentiment and Emotion Analyses

Figure 5 presents the average sentiment distribution of positive, negative, and neutral sentiments. For Instagram, the hashtags analyzed were #stillbirth and #stillbirthawareness, and for X, the hashtag analyzed was #stillbirth. The same time period, 2023 - 2024, was analyzed for both social media platforms. When comparing the 2 hashtags on Instagram, #stillbirthawareness had a higher proportion of positive sentiments and a lower proportion of negative sentiments than #stillbirth. In addition, when examining the same hashtag of #stillbirth across Instagram and X, the proportion of positive sentiments on Instagram was higher, while that of negative sentiments was lower.

XSL•FO
RenderX

Figure 5. Sentiment distribution (positive, negative, and neutral) across Instagram posts with the hashtags #stillbirth and #stillbirthawareness and X posts with the hashtag #stillbirth (2023-2024). Values represent the mean observed proportion of posts in each sentiment category, with Wilson 95% CIs.

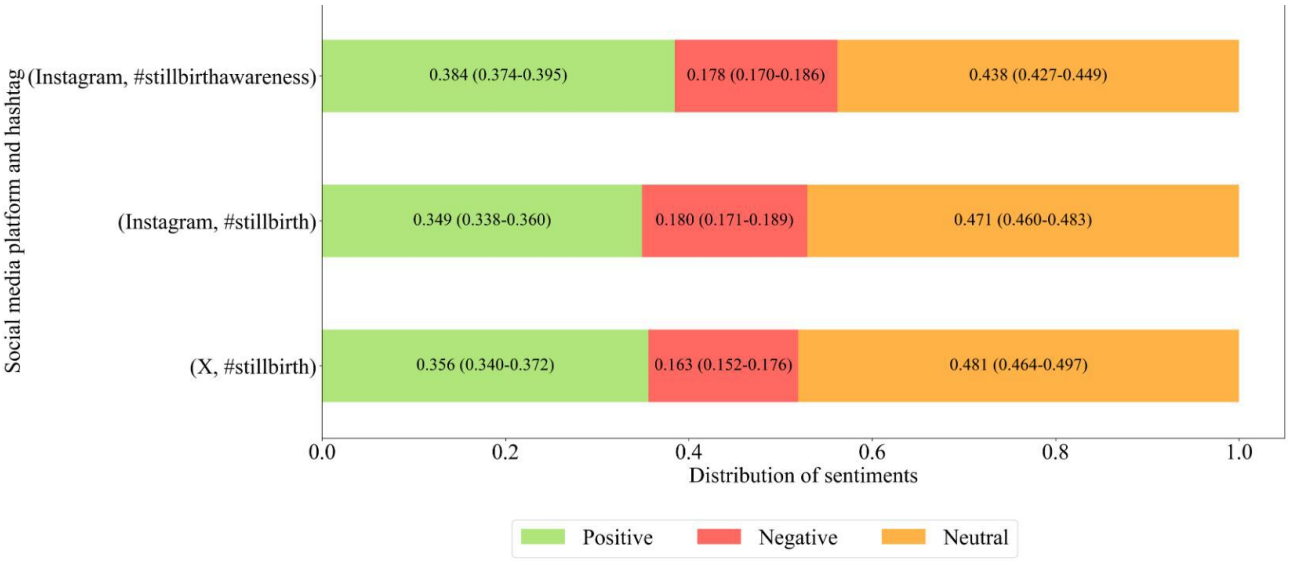


Figure 6 shows the distribution of emotions—fear, surprise, sadness, anger, disgust, joy, and neutrality—for the same set of hashtags across the 2 platforms. Emotions with scores below 0.04 were excluded from the figure annotations to enhance the figure clarity. Three dominant emotions were consistently observed across all hashtags on both X and Instagram: neutrality, sadness, and fear. In contrast, surprise, anger, and disgust were less commonly expressed on both platforms. When comparing the 2, fear was more pronounced on X, whereas sadness and joy appeared more frequently on Instagram.

Figure 6. Distribution of emotions (fear, surprise, sadness, anger, disgust, joy, and neutrality) across Instagram posts with the hashtags #stillbirth and #stillbirthawareness and X posts with the hashtag #stillbirth (2023–2024). Values represent the mean observed proportion of posts in each emotion category, with Wilson 95% confidence intervals.

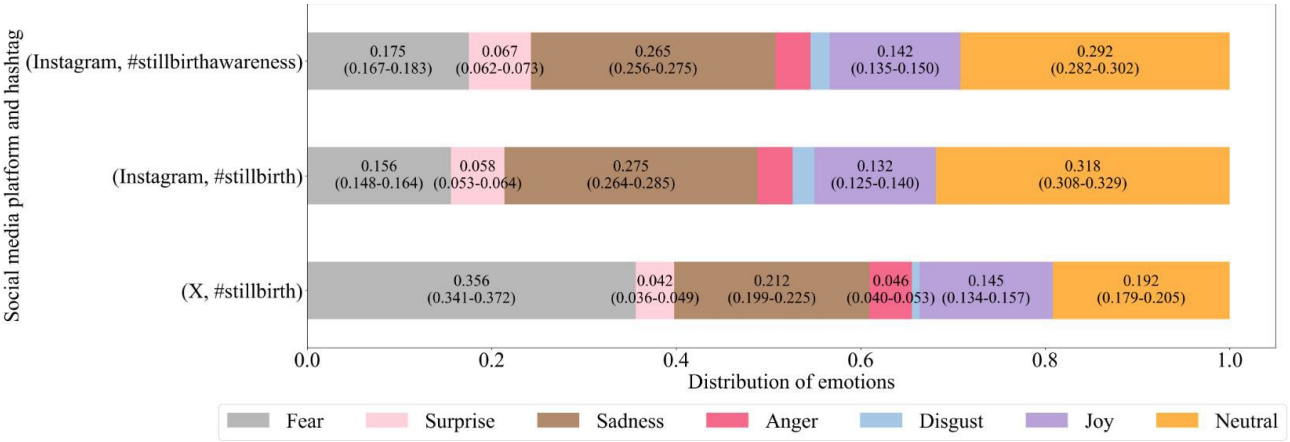

Figure 7 presents the average annual scores for sentiments (positive and negative) and selected emotions (fear, anger, sadness, and joy) in posts containing the hashtag #stillbirth on X between 2020 and 2024. The most prominent emotion across the entire period was fear, which consistently registered the highest among all emotional categories—particularly notable in the early years of the COVID-19 pandemic (2020 - 2021). Positive sentiments demonstrated a gradual rise throughout the period, with a sharp increase observed in 2024. In contrast, negative sentiments increased until 2022, after which they declined. Sadness steadily decreased over time while joy increased modestly during 2023 - 2024. Anger exhibited minimal year-to-year variation, remaining consistently low.

XSL•FO
RenderX

Figure 7. Annual trends in positive, negative, fear, anger, sadness, and joy scores for #stillbirth on X (2020-2024).

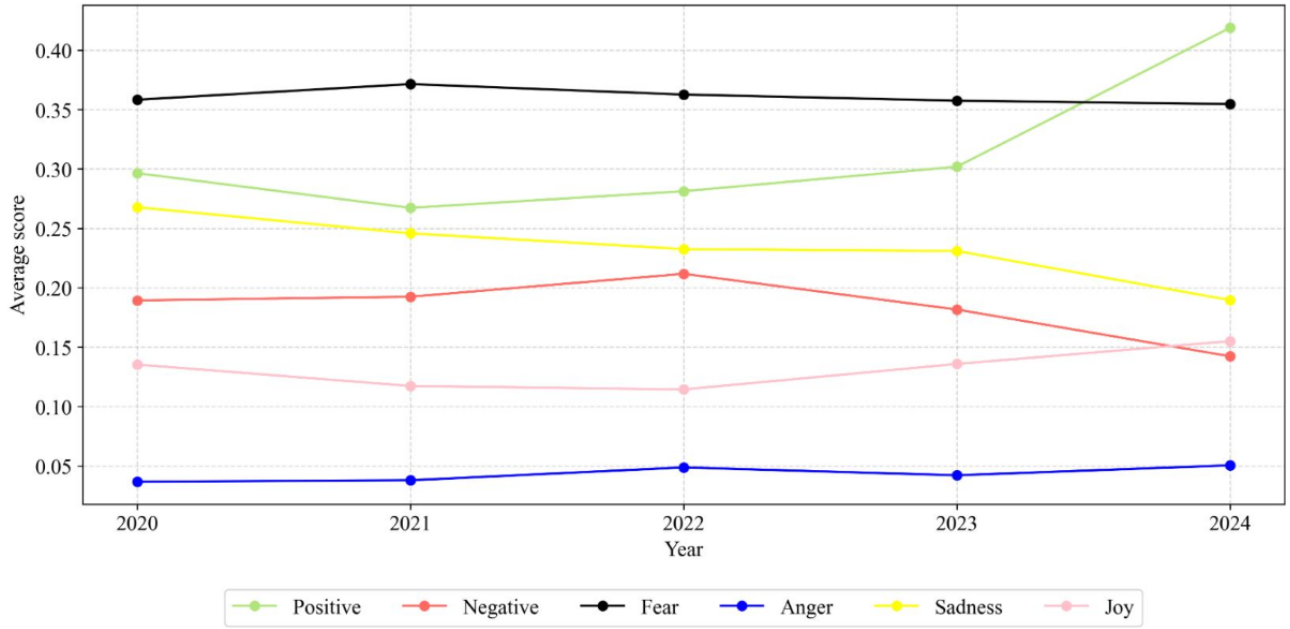

Image Analysis

To ensure statistical representativeness, the required sample size was calculated based on a population of n=7415 Instagram images, a 95% CI, and a ±5% margin of error, resulting in a target sample of 366/7415. The first sample of 366 images was used to develop the codebook. Two additional independent samples of 366 images each were subsequently categorized by 2 trained annotators.

The interrater reliability for the 2 coding samples was assessed using Cohen Kappa statistic, which measures agreement beyond chance and is reported with its 95% CI. In both samples, the agreement was strong: in sample 1, κ=0.837 (mean 0.836, SD 0.03; 95% CI 0.773 - 0.891), while in sample 2, κ=0.821 (mean 0.821, SD 0.03; 95% CI 0.755 - 0.879). The overlapping CIs indicate that there was no substantial difference in agreement between the 2 assessments, supporting the consistency and reliability of the coding procedure.

After calculating the distribution of categories within each sample, their similarity was assessed. The results demonstrated a near-perfect correlation between the 2 distributions based on their Pearson correlation (r=0.999; P<.001), along with a nonsignificant difference in categorical frequencies (χ^2_7=12.4; P=.09). These findings support the decision to pool the 2 samples for subsequent analyses, based on both the high interrater agreement and the absence of statistically significant divergence between the category distributions.

Table 4 presents the distribution of images across topics for the 2 independent samples (n=366 each) based on the predefined codebook. In both samples, the dominant category was “Image of text,” comprising text-based graphics with uplifting quotes, awareness messages, and supportive content relating to stillbirth, shared by both individuals and organizations. Excluding this category, most images were personal and intimate, with remembrance being the most common theme (44/366 in the first sample and 38/366 in the second). These included depictions of stillborn infants, memorial tributes, and symbolic representations of loss.

Table . The categorization of the randomly selected Instagram images, using the hashtag #stillbirth, into 4 themes: graphic expressions, parenthood, remembrance, and other (n=366).

Theme	Topic	Distribution sample 1, n (%)	Distribution sample 2, n (%)
Graphic expressions	Image of text	263 (71.9)	277 (75.7)
Graphic expressions	Illustrations	10 (2.7)	9 (2.5)
Parenthood	Family moments	11 (3)	5 (1.4)
Parenthood	Motherhood	5 (1.4)	10 (2.7)
Remembrance	Stillborn infant	14 (3.8)	14 (3.8)
Remembrance	Memorial tributes	25 (6.8)	22 (6)
Remembrance	Pregnancy	5 (1.4)	2 (0.5)
Other	None	33 (9)	27 (7.4)

XSL•FO
RenderX

Discussion

Principal Findings and Comparison With Existing Literature

The results of the hashtag co-occurrence network analysis for #stillbirth during 2023‐2024 (Figures 2-4) indicated that Instagram posts emphasized emotional expression and mental health, whereas the discourse on X was more oriented toward informational and public health-related content. Interestingly, X showed a strong presence of health-related hashtags, with #COVID19 ranking among the most prominent.

Analyzing tweets relating to vaccination or COVID-19 (Figure 1) revealed that in nearly 27.8% (149/536) of cases, the information that was shared was inaccurate. These findings indicate that stillbirth-related discourse on X is not solely focused on emotional and community support but also intersects with broader health debates and misinformation narratives.

Recent studies have explored machine learning approaches to detect health misinformation on social media [41,42,69,70,71]; however, gaps remain in real-time monitoring and addressing emotionally charged topics, such as stillbirth. The prevalence of inaccurate information that we identified underscores the need for targeted interventions to correct misinformation, particularly in sensitive health contexts. Of note, the immediate and widespread reach of platforms, such as X, means that information, both accurate and inaccurate, spreads quickly. Engaging authoritative figures is critical to steer the narrative [70]. Our findings highlight the spread of misinformation within social media and emphasize the importance of ensuring that accurate, evidence-based information reaches the public. It is essential to combat misinformation, particularly for individuals who have experienced stillbirth and may struggle with self-blame, fearing that vaccinations contributed to their loss. Providing clear, evidence-based information on social media can help to dispel these concerns, alleviate unnecessary guilt, and support informed decision-making regarding maternal health.

The evaluation of 3 topic modeling algorithms (NMF, LDA, and BERTopic) identified NMF as the most suitable method for processing our data (Table 2), based on its consistently superior coherence scores. This finding aligns with prior research demonstrating that NMF often outperforms traditional models, such as LDA in terms of topic coherence, particularly when applied to the short and noisy texts that are commonly found in social media contexts [72-74]. LDA is known to exhibit topic overlap and reduced stability when handling sparse data. Although BERTopic introduces an innovative approach by incorporating transformer-based embeddings, it frequently yields a high proportion of outliers, which undermines the interpretability [75]. Given the informal and fragmented nature of our datasets, NMF provided the most coherent and interpretable topic structures, making it the preferred algorithm for our analysis.

Our topic modeling analysis of posts on both X and Instagram shows that users predominantly share personal experiences of stillbirth, with dominant themes of honoring and remembering their babies, marking milestones (birthdays and anniversaries), and raising awareness and support. These findings are consistent with prior research on miscarriage and pregnancy-loss discourse in social media. For example, Dubbelman et al [76] and Putri et al [77] highlight themes of grieving, healing, support, gratitude, and informational posts, which reinforces our observation of remembrance and awareness-raising as central to stillbirth discourse. Similarly, Mercier et al [30] identified emotional disclosure as central to miscarriage posts on Instagram, a pattern that aligns with the personal storytelling we observed, though our findings extend these works by showing how these disclosures are accompanied by highly visual memorial practices unique to stillbirth. Callen and Oxlad [31] documented 5 forms of social support (informational, emotional, esteem-based, tangible, and network-based) in a Facebook miscarriage group, which parallels the supportive interactions present in our dataset and thus strengthens the interpretation of social media as a support infrastructure.

Our results extend prior work by showing that visual memorialization is a distinctive feature of stillbirth discourse, consistent with continuing bonds theory [21]. Although text-based images appear numerically common in our dataset (Table 4), stillbirth posts frequently incorporate highly expressive commemorations—such as photographs of stillborn infants, memorial tributes, and symbolic imagery—that differ from disclosures in miscarriage studies [76,77]. Unlike miscarriage, stillbirth typically involves full-term labor [1] and the physical birth of a visibly developed baby, intensifying the emotional impact and need for remembrance. Consequently, stillbirth-related content on Instagram not only displays unique platform dynamics and emotional depth but also illustrates how parents maintain continuing bonds with their infants through visual tributes. These images serve as enduring memorials that affirm the baby's existence, validate parental grief, and resist societal pressures to minimize or hasten recovery.

This visually anchored pattern aligns with research on stillbirth in social media. Hayman et al [78] showed that parents use photographs, symbolic imagery, linking objects, and rituals on Facebook to maintain ongoing relationships with the "born still," extending continuing bonds theory [21] into shared social spaces. Similarly, Sani et al [34] interpreted YouTube videos by bereaved mothers as modern mortuary rituals, transforming the platform into a digital cemetery. Within the broader literature on child death, not limited to stillbirth, Keskinen et al [79] identified images of child portraits, tombstones, mementos, drawings, and postdeath photographs. These categories closely mirror those found in our Instagram dataset, suggesting cross-platform consistency in the symbolic repertoire of grief. The close alignment with studies of child bereavement underscores that parents experiencing stillbirth engage in practices of remembrance akin to those of parents grieving a child, exemplifying continuing bonds theory, where stillbirth is affirmed as the genuine loss of a child and parents sustain their connection through symbolic and visual forms of remembrance.

Our sentiment analysis revealed a higher proportion of positive than negative sentiments (Figure 5)—an unexpected pattern for stillbirth. Manual review revealed that "highly positive" posts

XSL•FO
RenderX

on Instagram and X often mark milestones, remembrance, and love (eg, “Happy heavenly 14th birthday” and “Birthday cake made with love”), where positive words appear within grief. This exposes a limitation of automated sentiment classifiers, which may overascribe positivity in memorial contexts [80]. A continuing-bonds lens helps explain the mix, as users sustain ties to their babies through commemorations and affirmations [21,22], while platform communities provide support and alleviate disenfranchised grief [24]. The positive side of this mixed sentiment described above can be explained, at least in part, by incorporating continuing bonds theory into social media research. Such behavior can enable ongoing connections with posters’ memories of their babies [21,22]. This platform fosters community support and alleviates disenfranchised grievances [24].

Figure 6 shows that fear and sadness dominate over joy and neutral expressions, yielding an overall negative tone around stillbirth. Cross-platform differences are clear, with fear more prevalent on X, whereas sadness and joy are more common on Instagram. In addition, Instagram exhibits more positive and less negative sentiment than X. These patterns align with platform norms—X’s news- and debate-orientation tends to surface health-related fear and negativity [81], while Instagram’s visual, image-centric format fosters more emotionally expressive content [82-84].

Instagram’s visual environment can help legitimize parental grief and build supportive communities. Public health efforts could use curated awareness posts featuring family stories and commemorative content, brief influencer-led campaigns, and simple participatory prompts (eg, “light a candle for your baby”) with targeted hashtags to normalize bereavement and strengthen public understanding of stillbirth.

Future research should further explore how X’s real-time affordances amplify fear-based misinformation during crises, such as COVID-19, compared with Instagram’s visual curation. This will allow health policymakers to include such platforms as specific challenges in their fight against misinformation that falsely heightens pandemic-related anxiety in relation to stillbirth and related health concerns.

Strengths and Limitations

This study addresses key gaps in the literature on stillbirth discourse, including common limitations, such as small sample sizes, a single-platform focus, and a lack of emotion, visual content, and misinformation analyses. Using a large-scale, multiplatform (Instagram and X) dataset and a multimethod approach—including topic modeling, sentiment and emotion analyses, hashtag network analysis, manual image classification, and misinformation detection—this research provides a comprehensive understanding of how stillbirth is represented and discussed on social media. Notably, it highlights the unique visual memorialization practices on Instagram and the prevalence of misinformation on X, positioning the study as a substantial contributor to digital health communication and grief-related research fields.

This study has several limitations that should be considered when interpreting the findings. First, social media posts only reflect the content that users choose to share publicly, which introduces a selection bias. These expressions may not capture the full emotional journey or the more private aspects of grief that are experienced by families affected by stillbirth. While this limits the completeness of the emotional representation, our analysis focuses specifically on publicly shared narratives, providing valuable insights into the discourse that individuals elect to make visible in the digital public sphere.

Second, the study lacked demographic information about content creators. We could not determine whether a post was authored by a woman, a man, or an organization, nor infer details, such as the poster’s age, cultural background, or personal experience with stillbirth. This limited our ability to analyze how this discourse might differ across demographic groups. Future work should explore ways to ethically incorporate user metadata or analyze verified support group discussions where roles and identities may be more clearly indicated.

Third, the time frame of the Instagram data (limited to 2023 - 2024 due to API restrictions) constrained our ability to conduct a longitudinal analysis. As a result, we could not observe how stillbirth-related discourse evolved over a broader period. In contrast, the X data spanned the period of 2020 - 2024, only allowing for a temporal analysis on that platform. To enable a meaningful comparison between the 2 platforms, we restricted the time frame for both datasets to the overlapping period of 2023 - 2024. This allowed for consistent cross-platform analysis while minimizing temporal biases.

Fourth, our reliance on automated sentiment and emotion analysis tools introduced limitations in interpreting emotional tone. While these transformer-based models are valuable for large-scale analysis, they are not always fully accurate and may struggle to capture context-dependent nuances, including emotional ambivalence, sarcasm, or irony [80]. To mitigate this limitation, we manually reviewed a subset of posts that had been classified with extreme sentiment scores. In addition, we conducted a deeper analysis of the emotions expressed in the posts—such as sadness, fear, and anger—by using emotion detection techniques that can capture more nuanced emotional states beyond the basic positive, negative, and neutral sentiment categories. This combination allowed us to interpret the complex emotional landscape associated with stillbirth-related content more thoroughly.

Future Directions

Future research should incorporate user metadata, where available, to better distinguish between personal narratives and institutional messaging, providing an understanding of how different entities engage in stillbirth-related discussions on social media. Future studies should also incorporate historical data to enable comprehensive time-series analyses.

Conclusions

This study provides a comprehensive view of stillbirth-related discourse on Instagram and X, showing platform-specific patterns. Instagram posts emphasized emotional expression and mental health, whereas X posts focused more on public health and informational topics (eg, COVID-19). Topic modeling indicated that discussions centered on honoring babies, raising

XSL•FO
RenderX

awareness, and providing support. Sentiment analysis showed more positive than negative sentiment overall, reflecting resilience, hope, and remembrance; however, fear and sadness were the dominant emotions. Fear was more prevalent on X, while Instagram displayed more sadness and joy, consistent with its more personal, visually expressive environment. Image analysis highlighted Instagram's visual tributes—such as photographs, gravesites, and symbolic imagery—which function as digital memorials that validate parental grief and community support.

Fear on X likely relates to the rapid, real-time spread of content and the presence of COVID-19 vaccine-related claims. Notably, 27.8% (149/536) of posts referencing stillbirth and vaccination or COVID-19 contained misinformation, underscoring the need for evidence-based communication and careful interpretation of platform dynamics. This study underscores the role of misinformation in shaping social media discourse, particularly on X, where inaccurate claims about COVID-19 vaccines and stillbirths appear and amplify fear-based narratives. Pregnant women who are exposed to such misinformation may avoid vaccination due to unfounded fears, while bereaved mothers may internalize guilt, believing that vaccination contributed to their loss. Ensuring that accurate health information reaches the public is essential for countering such harmful effects.

Future work could develop platform-aware approaches to counter misinformation and support bereaved communities. On X, agencies could collaborate with the WHO and local maternal-health organizations to deploy real-time, evidence-based messages (eg, verified infographics) timed to peaks in misinformation, potentially amplified through influencers and health advocates with lived experience. Real-time monitoring could help surface emerging myths and inform rapid responses. On Instagram, health care and maternal-health organizations could design guided hashtag campaigns that pair personal narratives with accurate resources to normalize conversation about loss. Training programs in digital health communication could help clinicians engage compassionately and effectively across platforms.

As this study lacked user demographics, engagement metrics, and historical data from both platforms, future studies could incorporate longitudinal traces and richer metadata to improve generalizability and track trends over time. Further work could also examine how X's real-time affordances amplify fear-based narratives during crises and evaluate which platform-tailored interventions are most effective at reducing misinformation and supporting bereaved families.

Abstract

Background: In recent years, there has been a dramatic increase in the popularity and use of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) for weight loss. As such, it is essential to understand users' real-world discussions of short-term, long-term, and co-occurrent adverse events associated with currently used GLP-1 RA medications.

Objective: This study aims to quantitatively analyze temporal and co-occurrent GLP-1 RA adverse event trends through discussions of GLP-1 RA weight loss medications on Facebook from 2022 to 2024.

Methods: We collected 64,202 Facebook posts (59,293 posts after removing duplicate posts) from January 1, 2022, to May 31, 2024, through CrowdTangle, a public insights tool from Meta. Using English language social media posts from the United States, we examined discussions of adverse event mentions for posts referencing 7 GLP-1 RA weight loss product categories (ie, semaglutide, Ozempic, Wegovy, tirzepatide, Mounjaro, Zepbound, and GLP-1 RA as a class). All analyses were conducted using Python (version 3; Python Software Foundation) in a Google Colab environment.

Results: Temporal time series analysis revealed that the GLP-1 RAs' adverse event mentions on social media aligned with several key events: the Food and Drug Administration's approval of Wegovy for pediatric weight management in December 2022, increased media coverage in August 2023, celebrity endorsement in December 2023, and Medicare Part D coverage expansion for weight loss medications in March 2024. Gastrointestinal (GI)–related adverse events (general term) were most prevalent for posts mentioning the GLP-1 RA class (210/4885, 4.30%) and Mounjaro (241/4031, 5.98%). In contrast, the most prevalent adverse event mentions noted for tirzepatide were headache (78/4202, 1.86%) and joint pain (71/4202, 1.69%). Hypertension (13/1769, 0.73%) was frequently mentioned in Zepbound posts, while pancreatitis was commonly associated with Mounjaro posts (44/4031, 1.08%), and 2.85% (139/4885) of posts broadly referring to the GLP-1 RA class. Furthermore, an integrated node network analysis revealed 3 distinct GLP-1 RA adverse events–mentioned clusters: cluster 1 (purple) contained allergies, anxiety, depression, chronic obstructive pulmonary disease, fatigue, fever, hypertension, indigestion, insomnia, gastroesophageal reflux disease, hives, swelling, restlessness, and seizures. Cluster 2 (pink) contained constipation, dehydration, headache, diarrhea, dizziness, hypoglycemia, sweating, and jaundice. Cluster 3 (brown) contained GI symptoms, such as nausea, pancreatitis, rash, and vomiting. The GI symptoms, such as nausea, vomiting, pancreatitis, diarrhea, and indigestion, were strongly associated together (≥100 co-occurrence mentions), while the mentioned neurological symptoms, such as anxiety, depression, and insomnia, were highly correlated with each other (50 - 100 co-occurrence mentions).

Conclusions: This social media study highlights the adverse event mention patterns for posts referencing GLP-1 RA medications. While further research is needed to rigorously examine and validate these findings, this study demonstrates the importance of

XSL•FO
RenderX

monitoring social media discussions to predict novel, underreported, or rare drug adverse events, thereby improving patient care, clinical research, and health policy interventions.

KEYWORDS

social media; semaglutide; tirzepatide; Ozempic; Wegovy; Mounjaro; Zepbound; GLP-1 RAs; adverse events; obesity management; weight loss medication

Introduction

In recent years, there has been a dramatic increase in the popularity and use of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) for the treatment of type 2 diabetes and obesity [1]. The Food and Drug Administration (FDA) first approved Ozempic (semaglutide) and Mounjaro (tirzepatide) for the management of type 2 diabetes in December 2017 and May 2022, respectively. Wegovy (semaglutide) and Zepbound (tirzepatide) were then approved for the management of obesity and overweight in June 2021 and November 2023, respectively. Given that nearly 38 million US adults are living with diabetes and more than 100 million have obesity, the increased demand for these drugs has contributed to an alarming global shortage of medications for people in need [2,3]. Furthermore, the low availability, high costs, and inconsistent and inadequate insurance coverage of GLP-1 RAs have contributed to the rise of compounded versions of GLP-1 RAs. However, while often lower in cost and more readily available (including without a prescription), compounded GLP-1 RAs have unknown dosage, safety, and efficacy profiles [4,5].

An important consideration for GLP-1 RAs' use is their adverse event profile, including significant GI discomfort and other potential physical and psychological symptoms [6]. GLP-1 RAs' functions include stimulating glucose-dependent insulin secretion, inhibiting glucagon secretion, and delaying gastric emptying [7]. These mechanisms of action contribute to reducing blood glucose levels and facilitating weight loss. However, by reducing patients' appetite and nutritional intake, GLP-1 RAs may lead to malnutrition, dehydration, and rapid loss of both fat and lean (ie, muscle and skeletal) body mass [8]. Previous clinical studies have discovered prevalent adverse events associated with GLP-1 RAs, including GI symptoms, such as nausea, diarrhea, vomiting, and reduced appetite [9]. Others revealed notable mental health adverse events, including insomnia, anxiety, and depression [6,10]. Importantly, the individual experience with medications—concerning effectiveness, tolerability, and safety—may differ among those taking medications in the real world compared with those enrolled and studied in clinical trials, and some events may be too infrequent to be detected in clinical trials. Moreover, rare adverse events may not be ascertained in clinical trial protocols. Therefore, further research is necessary to understand the complex adverse events of GLP-1 RAs on physical and mental health conditions experienced and reported by individuals consuming these medications in contemporary practice.

Since the most potent GLP-1 RAs (including the dual glucose-dependent insulinotropic polypeptide and GLP-1 RA, tirzepatide) were introduced into practice recently, it is important to monitor for emerging adverse events of these medications [11]. Clinical studies identify many of GLP-1 RAs' adverse events, but they cannot capture the totality of adverse events experienced by and important to patients. For instance, clinical studies' sample size and duration of follow-up are often limited, reducing the likelihood of detecting rare or long-term adverse events. Individuals taking GLP-1 RAs also differ from those included in clinical trials as they likely have different clinical profiles, lifestyles, environmental contexts, and dietary and physical activity cointerventions. Furthermore, the robustness of education and clinical monitoring available before and while taking GLP-1 RA medications contributes to individuals' perceptions of the medications. It is also essential to monitor adverse events of compounded GLP-1 RA products, whose safety profiles are expected to differ from the FDA-approved products and are largely unknown at this time.

Social media platforms provide a relatively untapped, extensive source of public discussion from which health professionals can develop targeted interventions. A meta-analysis study analyzed social media pharmacovigilance studies and FDA reports and found that more adverse event discussions on social media corresponded to a higher hazard and faster drug product recall [12]. Therefore, social media may reveal invaluable insights regarding mentioned adverse events that may not be presented in other clinical or observational studies.

Building upon prior findings, this social media–based study aims to use advanced data extraction techniques and conduct quantitative analyses to investigate mentioned GLP-1 RA adverse event phenotypes. Our approach harnesses social media data as a complement to traditional clinical and pharmacovigilance data sources to identify user-reported mentions of adverse events for posts referencing GLP-1 RAs. Additionally, we examine temporal trends of social media GLP-1 RA discussions to identify factors that drive their popularity from Oprah Winfrey's endorsement of GLP-1 RAs [13] to Medicare's coverage expansion [14]. Finally, we identify clusters of co-mentioned adverse events, introducing a novel way to characterize adverse event interconnections and risk profiles. Quantitative temporal analyses are vital to highlight possible unreported GLP-1 RA adverse events, providing timely information to inform community-driven interventions to promote public health awareness about GLP-1 RA use.

Methods

Data Source

We collected Facebook posts through CrowdTangle, a public insights tool from Meta [15] and engagement metrics (eg, views and post likes). CrowdTangle has been discontinued. Currently

XSL•FO
RenderX

available tools for researchers include Meta Content Library and Content Library API [16]. CrowdTangle provides data from public accounts, including 7 million Facebook pages, groups, and verified profiles. Data collection can be refined by specifying various parameters such as time frame, specific pages, groups or profiles, keywords or tags, language, geolocation, and presence of memes. The returned data include posts, image URLs, image caption text, date of the post, and engagement metrics (eg, views and post likes).

Data Preparation (Sample and Inclusion Criteria)

Using CrowdTangle, we obtained and processed Facebook English language posts by US-based users between January 1, 2022, and May 31, 2024, that mentioned weight loss medications, specifically "Semaglutide/semaglutide," "Ozempic/Ozempic/ozempy," "Wegovy/wegovy," "Tirzepatide/tirzepatide," "Mounjaro/mounjaro," "Zepbound/zepbound," and "GLP-1/GLP-1s/GLP-1 agonist/GLP-1 RAs." To limit our collection to US-based discussions on weight loss medications, we leveraged CrowdTangle's "Page Admin Country" filtering parameter. This field identifies the country of the primary administrators of Facebook Pages. Because the filter was not available for Facebook Groups, we collected posts derived solely from Facebook Pages where the United States was listed as the "Page Admin Country. Among these posts, we identified those that mentioned any potential short-term or long-term adverse events, defined as any undesirable experience associated with a drug or treatment [17] (Table 1). The list of adverse events was determined based on past literature, clinical expertise, and the SIDER database version 4.1, which cataloged 5868 documented adverse events for 1430 commercially available drugs [18]. To examine the magnitude of adverse events mentioned for weight loss medications, duplicate posts with the same message were filtered out.

XSL•FO
RenderX

Table . List of adverse events associated with different weight loss medications.

Adverse event category	Adverse event
Gastrointestinal	• Gastrointestinal (general term) • Nausea • Vomiting • Diarrhea • Constipation • Abdominal pain • Loss of appetite • Indigestion • Jaundice • Pancreatitis • Gallbladder issues • Gastroesophageal reflux disease • Liver damage
Neuromuscular	• Headache • Dizziness • Seizures • Muscle cramps • Tingling sensation • Joint pain • Muscle weakness • Back pain
Cardiovascular and respiratory	• Persistent cough • Swelling • Increased heart rate • Shortness of breath • Hypertension • Chronic obstructive pulmonary disease • Blood clots • Heart palpitations
Dermatologic and immunologic	• Rash • Sweating • Hives • Sore throat • Fever • Dry mouth • Hair loss • Allergies
Endocrine and metabolic	• Elevated blood sugar levels • Irregular menstrual cycle • Thyroid tumor • Erectile dysfunction • Kidney damage • Hypoglycemia
Mental health and behavioral	• Depression • Anxiety • Mood swings • Insomnia • Restlessness
General symptoms	• Vision changes • Fatigue • Dehydration

Statistical Analysis

Descriptive analyses were conducted using Python (version 3) in a Google Colab environment. For each weight loss medication, we calculated the frequency and percentage of adverse events mentioned—calculated as the total mention of a certain adverse events over the total number of posts for a particular weight loss medication. To examine temporal trends, we recorded the total frequency of adverse events by calendar month. We plotted frequency and percentage of adverse events

XSL•FO
RenderX

mentions from January 2022 to May 2024 to assess for changes in the mentions of adverse events for four specific events: (1) FDA approval of Wegovy for weight management in children aged 12 - 17 years in December 2022 [19], (2) increased media coverage of GLP-1 RA medications on TikTok and other platforms in August of 2023 [20], (3) Oprah Winfrey's endorsement of weight loss medications in December 2023 [14], and (4) expanded FDA indication for Wegovy for the prevention of cardiovascular events and mortality in adults with obesity and cardiovascular disease in March 2024, paving the way for Medicare coverage of weight management medications for reduction of cardiovascular events [21].

To investigate the co-occurrence of adverse events mentioned, a cluster analysis was conducted. Clusters were formed based on the Louvain community detection algorithm using the Python library (python-louvain) [22], which can detect communities (via modularity optimization) and subsequently improve the quality of community structures [23]. A spring layout algorithm for positioning with k=7.8 and the number of iterations=100 was applied to arrange the nodes to effectively repel them to minimize overlap and enhance the clarity of the node-network structure [24]. Using this method, we constructed a network of adverse events mentioned where 2 nodes mentioned in the same post are connected by an edge. A cluster was based on the co-occurrence of mentioned adverse events. The size of each node reflects the frequency of the mentions, while the width of each edge (thickness of the lines) corresponds to its weight, indicating the strength of co-occurrence between comentioned adverse events.

Ethical Considerations

This study was determined to be not human participant research by the University of Maryland College Park Institutional Review Board (2072551-1). In addition, the social media posts were anonymized, upholding user privacy.

Results

Descriptive Patterns of Adverse Events

Table S1 in Multimedia Appendix 1 shows the FDA-reported adverse events of the drugs examined in this study with their brand name, generic name, and approved indication for the drug. We collected 64,202 (59,293 posts after removing duplicates) posts that included a discussion of the 7 weight loss products. Of these posts, 28.9% (17,146/59,293) on semaglutide, 31.6% (18,733/59,293) on Ozempic, 14.4% (8527/59,293) on Wegovy, 7.1% (4202/59,293) on tirzepatide, 6.8% (4031/59,293) on Mounjaro, 3.0% (1769/59,293) on Zepbound, and 8.5% (4885/59,293) referenced the GLP-1 RA class without mentioning a specific drug. Among all the posts, 13.8% (8171/59,293) mentioned adverse events (Table 2). Table 2 shows the counts and percentages of all posts about each medication that mentions specific adverse events. For example, nausea is mentioned in 3.23% (185/4885) of posts referencing GLP-1. Within each column of the different medications, adverse event mentions are depicted in decreasing frequency within broad categories of adverse events such as "Gastrointestinal" or "Mental Health and Behavior," where the highest percentage within the category is near the top, and the lowest percentage is near the bottom. The percentages in boldface represent the highest frequency within each column.

[a]Percentage = (Number of posts mentioning the adverse event for a medication/Total number of posts about the medication) × 100. The values in boldface indicate the most commonly mentioned adverse event for the particular GLP-1 RA category.

[b]GLP-1: glucagon-like peptide-1.

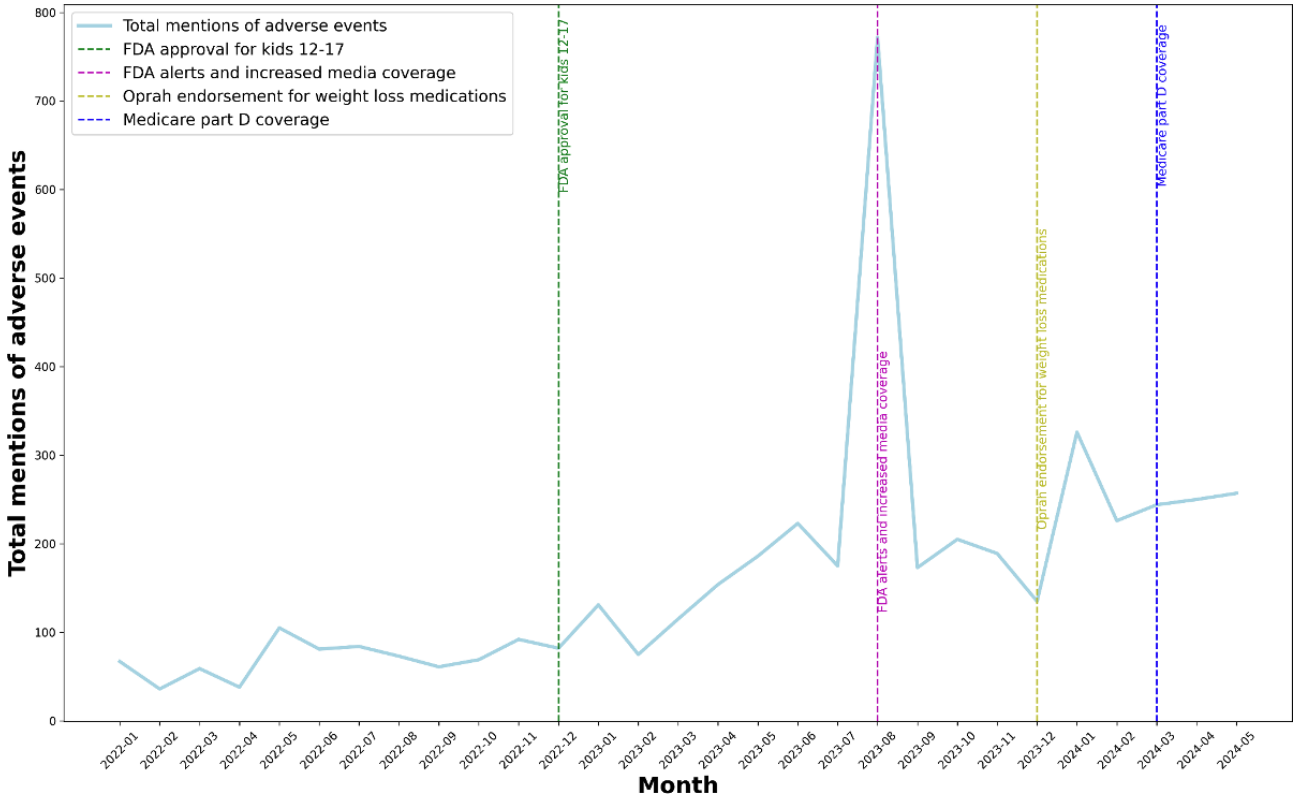
[c]The values in boldface indicate the most commonly mentioned adverse event for the particular GLP-1 RA category.

[d]GERD: gastroesophageal reflux disease.

[e]COPD: chronic obstructive pulmonary disease.

Distinct GLP-RA adverse events mention patterns emerged. General (nonspecified) GI concerns were among the most frequently reported, representing 4.3% (210/4885) of general GLP-1 RA posts and 6.0% (241/4031) and 3.5% (296/8527) of posts referencing Mounjaro and Wegovy, respectively (Table 2). A lower percentage of GI issues were reported in posts mentioning Ozempic (488/18,733, 2.6%), semaglutide (95/17,146, 0.5%), tirzepatide (19/4202, 0.5%), and Zepbound (16/1769, 0.9%). Nausea was among the most commonly reported specific symptoms, appearing in 3.2% (158/4885) of posts about general GLP-1 RA use, 2.1% (86/4031) of posts about Mounjaro and Wegovy each, 1.7% (317/18,733) about Ozempic, and 1.3% (23/1769) of posts about Zepbound; it was mentioned in approximately 1% (197/17,146) of semaglutide and tirzepatide posts. Vomiting was also mentioned in 3.8% (153/4031) of Mounjaro posts, 2.7% (228/8527) of Wegovy posts, 2.3% (113/4885) of general GLP-1 RA posts, 1.6% of Ozempic posts (308/18,733), and 0.6% of semaglutide (99/17,146) and Zepbound (11/1769) posts each. Pancreatitis was a concern that appeared in 2.9% (139/4885) of general GLP-1 RAs posts.

Several other adverse events were referenced in posts. Depression was noted across various GLP-1 RAs, although it was less prevalent than general GI concerns or nausea and vomiting (Table 2). Wegovy posts mentioned depression 1.6% (134/8527) of the time, while general GLP-1 RAs (42/4885), Ozempic (165/18,733), and semaglutide (151/17,146) posts discussed depression 0.9% of the time. Depression was less often noted in Zepbound (9/1769, 0.6%), Mounjaro (19/4031, 0.5%), and tirzepatide (13/4202, 0.4%)-related posts. Hair loss was more prominent in Mounjaro posts (80/4031, 2.0%) than in general GLP-1 RA (48/4885) or Zepbound (17/1769) posts, which were discussed in 1.0% of posts each. Headaches (78/4202) and joint pain (71/4202) appeared in 2.0% of tirzepatide posts, compared with 0.6% (111/17,146) and 0.7% (97/17,146) of semaglutide posts. Fatigue was also reported across all weight loss medications. Table S2 in Multimedia Appendix 1 shows the percentage of posts that mention each adverse event by medication. For example, 1.69% (317/18,733) of posts mentioning Ozempic adverse events include “nausea.” Figure S1 in Multimedia Appendix 1 displays the prominent adverse events frequencies (total≥75) for the weight loss medications.



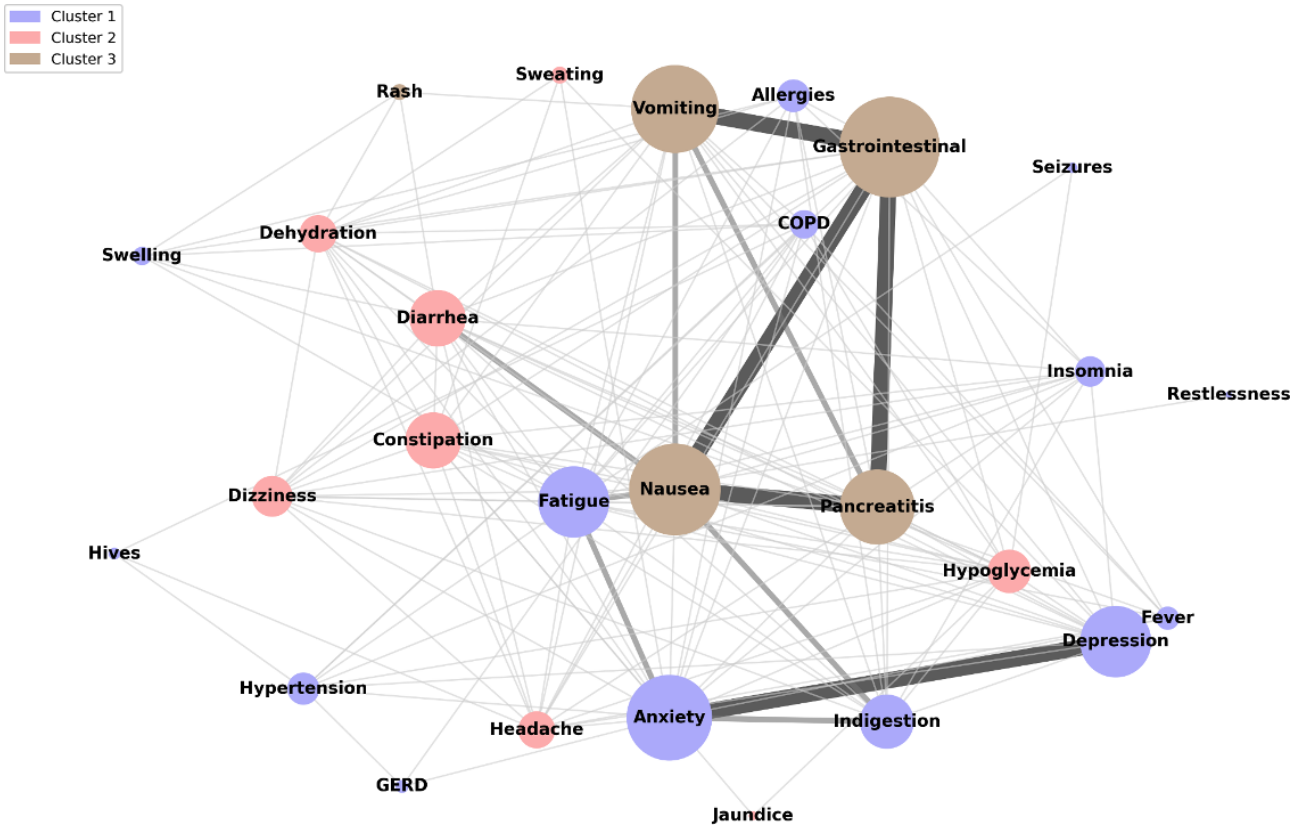
Temporal Trends With Key Events

We examined the potential impact of several key events occurring during the temporal analysis period on observed side effect mention trends (Figure 1). In December 2022, the FDA approved Wegovy for the treatment of obesity in children aged 12 - 17 years [19]. This event was followed by increased media coverage in August 2023 that highlighted potential adverse event mentions associated with these drugs and interactions with other medications, coinciding with a surge in media coverage across social media platforms including Reddit, TikTok, Instagram, Facebook, and Twitter [19]. At the end of 2023, Oprah Winfrey publicly endorsed the use of weight loss medications (December 14, 2023) [14], while Medicare Part D expanded its coverage for weight loss medications starting in March 2024 [21]. Figure S2 and Table S3 in Multimedia Appendix 1 show the percentage of adverse events mentioned to total drug mentions over time. Of note, although the number of adverse events mentioned has increased over time, the percentage of posts that mention adverse events has decreased over time (Figure S2 in Multimedia Appendix 1), indicating

XSL•FO
RenderX

changes in the composition of these discussions from adverse events to other topics related to these medications.

Figure 1. Temporal time series analysis of mention of all adverse events from January 2022 to May 2024. FDA: Food and Drug Administration.



Co-Occurrence Network Trends

In a network analysis of noted adverse events for posts referencing these medications, a total of 2618 adverse event co-occurrence interactions and 27 nodes (circles representing adverse events) were identified from the dataset. As shown in Figure 2, 3 distinct communities were formed, each representing a grouping of adverse events mentioned with similar characteristics based on their high-frequency co-occurrence patterns. Cluster 1 (purple) contains allergies, anxiety, depression, chronic obstructive pulmonary disease, fatigue, fever, hypertension, indigestion, insomnia, gastroesophageal reflux disease, hives, swelling, restlessness, and seizures. Cluster 2 (pink) contains constipation, dehydration, headache, diarrhea, dizziness, hypoglycemia, sweating, and jaundice. Cluster 3 (brown) contains GI symptoms, such as nausea, pancreatitis, rash, and vomiting. Interactions with a co-occurrence count of ≥100 were visualized with thick lines, while those with counts between 50 and 100 were shown with a moderately thick line, and interactions with counts <50 were represented by the thinnest lines. As depicted in Figure 2, nausea, vomiting, pancreatitis, and GI distress are connected by thick lines, reflecting their strong co-occurrence. Anxiety and depression are also highly correlated. Next, the intermediately thick lines reveal moderately strong associations between fatigue, anxiety, indigestion, nausea, diarrhea, vomiting, and pancreatitis. The most common co-occurrences are GI and vomiting (298), GI and pancreatitis (152), GI and nausea (132), anxiety and depression (210), and nausea and pancreatitis (124). Moderate co-occurrences include anxiety and indigestion (96), anxiety and fatigue (76), and fatigue and nausea (74).

Discussion

Principal Findings

This study used Facebook data to examine the adverse events discussed on the social media platform with respect to different GLP-1 RAs commonly used for weight management from January 2022 to June 2024. Semaglutide and Ozempic (the brand of semaglutide FDA-approved for the treatment of type 2 diabetes) were the most mentioned products, while Wegovy (the brand of semaglutide FDA-approved for the treatment of obesity), tirzepatide, Mounjaro (the brand of tirzepatide FDA-approved for the treatment of type 2 diabetes), Zepbound (the brand of tirzepatide FDA-approved for the treatment of obesity), and the overall GLP-1 RA class were discussed less often, reflecting the public's attention to Ozempic as a prominent GLP-1 RA agent and the first medication receiving market approval. The most commonly described adverse events were GI symptoms for most GLP-1 RA categories, while for tirzepatide social media posts, the most prevalent ones were headache and joint pain. The popularity of these medications and mentions of their adverse events surged in alignment with novel indications, approvals (particularly for children), and celebrity endorsement. We also uncovered 3 distinct clusters of referenced co-occurring adverse events, characterized by (1) somatic or metabolic symptoms (purple), (2) neurological or inflammatory discomfort (pink), and (3) gastrointestinal distress (brown). Together, these findings offer a glimpse into the public's social media discussions of adverse events related to GLP-1 RA medications. Posts discussing GLP-1 RAs as a class as well as specific posts discussing Mounjaro were most likely to mention adverse events (1138/4885, 23.3% and 868/4031, 21.5%, respectively), while posts discussing the other products (ie, semaglutide, tirzepatide, and Wegovy) included adverse events <10% of the time. However, it is important to note that Mounjaro and Zepbound (both tirzepatide products) were approved during the study period in May 2022 and November 2023, respectively, while Ozempic and Wegovy (both semaglutide products) were approved in 2017 and 2021, respectively. Thus, temporal differences in market access may have impacted the public's discussion of adverse events for these medications. More recently approved medications may garner more discussion about adverse events, while discussions of medications that have been available and used longer may have shifted toward other topics, such as health insurance coverage or novel indications [25,26]. GLP-1 RA adverse events may be dose dependent and diminish with time. Nevertheless, in our study, we did not collect dose information or include it in our analysis as doses were not consistently posted or available, and it was not possible to assess what dosages of the medications the adverse events were experienced on and attributed to.

GI adverse events, including nausea and vomiting, were the most frequently mentioned for all the drugs, consistent with both clinical trial and social media analysis data [27,28]. Additionally, our study found that Ozempic and all semaglutide medications were more frequently associated with reports of depression and anxiety than other weight loss medications. While our analyses cannot establish a causal relationship or provide a mechanistic pathway, the clustering of depressive symptoms among individuals discussing semaglutide is

XSL•FO
RenderX

concerning and builds upon prior literature, raising concerns about an increased risk of suicidal ideation with semaglutide therapy [29,30]. Therefore, it may be important to monitor individuals treated with semaglutide—and other GLP-1 RAs—for mood concerns until more conclusive clinical data are available. Nevertheless, it remains to be determined whether semaglutide impacts mood through its actions on the central nervous system and reward pathways, or whether individuals at high risk for depression are more likely to take semaglutide and share their concerns on social media.

Not surprisingly, we found significant increases in social media posts—both overall and those discussing medication adverse events—corresponding to the broader context during our study period between January 2022 and June 2024. After the FDA approved Wegovy for weight management in children aged 12 - 17 years in December 2022 [19], there was a corresponding increase in adverse event mentions in the following months. This trend aligns with a previous study that highlights potential adverse event risks, including GI issues, mental health concerns, and metabolic changes in younger populations [31]. During August 2023, there was an increase in media coverage of GLP-1 RA—particularly of compounded GLP-1 RA products—across social media platforms, concurrent with an FDA warning against use of unapproved GLP-1 RA drugs. This time period also corresponded to a second spike in adverse event mentions as illustrated in Figure 2 [32]. Our findings are consistent with an earlier report that revealed increased patient concerns and discussions about GLP-1 RA adverse events following increased media attention [33]. The next spike in social media discussions was observed after Oprah Winfrey shared that she had used weight loss medication as part of her health and fitness routine in December 2023, which contributed to a 400% increase in semaglutide prescriptions [34]. This surge coincided with a rise in public discourse about associated GI adverse events as well as more severe complications such as pancreatitis and kidney damage [35,36]. Finally, there was an increase in mentions of adverse event concerns after the March 2024 FDA expansion of Wegovy's approved indication to include the prevention of cardiovascular events in patients with obesity and cardiovascular disease, thereby paving the way for Medicare coverage of Wegovy for patients with obesity but not type 2 diabetes. A subsequent public poll by the Kaiser Family Foundation similarly noted an increase in public discussions of GLP-1 RA adverse events, including GI issues and fatigue [37]. Unlike previous studies, our study uniquely analyzed real-time social media discussions on GLP-1 RA medications, capturing shifts in adverse events mentioned in response to key regulatory and media events.

Previous clinical studies have also examined the adverse event profiles of semaglutide and tirzepatide GLP-1 RAs receptor agonists. For instance, in SURPASS-2, a 40-week phase 3 clinical trial comparing tirzepatide and semaglutide in 1879 participants with type 2 diabetes [10], the most commonly reported adverse events were GI: nausea, diarrhea, vomiting, and reduced appetite. Social media results not only corroborated the high prevalence of these GI adverse events but also exposed some more severe and rare adverse events, such as pancreatitis, which appeared more prominently in social media discussions than in clinical trials. For example, pancreatitis, which was experienced by 0.6% of patients in SUSTAIN-2, was discussed in 2.85% (139/4885) of GLP-RA's social media posts. Joint pain was an additional adverse event that appeared on social media but is not yet attributed to these medications in clinical trials [38]. Similarly, headache was the most frequently mentioned adverse events mentioned in 1.86% (78/4202) of tirzepatide social media posts. In contrast, a clinical study revealed reduced headache risk in patients with hypertension treated with tirzepatide [39]. These findings warrant further clinical investigation to examine the complex adverse events of tirzepatide on mitigating and exacerbating headaches and other neurological symptoms. Additionally, our study identified 3 unique clusters of adverse event profiles attributed to GLP-1 RA agents. We found co-occurrences between GI adverse events, such as nausea, vomiting, pancreatitis, and GI distress. Anxiety and depression were also highly correlated with each other. These findings build upon an earlier mixed methods study that analyzed Reddit, YouTube, and TikTok to assess the impact of GLP-1 RAs on mental health [7], finding 3 overarching mental health–related themes: insomnia (n=620 matches), anxiety (n=353), and depression (n=204); these mental health conditions were also detected in our analysis. Another study analyzed Twitter, Reddit, PubMed, SIDER, and manufacturer reports to identify clusters of adverse events frequently co-mentioned in the same posts [23]. The most prevalent cluster of co-mentioned adverse events was GI adverse events, corroborating our analytical findings. Next, mental health adverse events were a frequent cluster, aligning with the neurological adverse events cluster in our integrated node network analysis. This study not only leveraged a novel platform, Facebook, to reveal additional insights into relationships between comentioned adverse events but also corroborated the results of previous studies using similar methodologies. Our broader co-occurrence trends reveal broad adverse event categories that can be further explored to analyze individual differences between patients. Further clinical research is necessary to understand the complex relationships of co-occurring adverse events.

Strengths and Limitations

This quantitative social media analysis study has several strengths. Primarily, it evaluated adverse event profiles attributed by individuals to different GLP-1 RA agents over a 2-year period and across 63,023 posts. Social media posts represent a wide range of individuals, including those from diverse backgrounds who are underrepresented in clinical trials (racial and ethnic minority patients, women of childbearing age, rural residents, etc), in different drug markets, and from all regions of the United States [40]. Facebook is a popular social media platform with 68% of US adults using this digital platform in 2023 [41]. On social media, people have the opportunity to share their real-world experiences, beliefs, concerns, and outcomes and may be more likely to report some experiences they may not report in an in-person study.

However, the study's limitations must also be taken into consideration. While in general, social media users represent a diverse sample, we do not know the demographic characteristics of the social media users in our specific dataset. Symptoms

XSL•FO
RenderX

mentioned in these posts are self-reported, and we cannot discern whether they were personally experienced, represent concerns about potentially experiencing those adverse events, or were posted in response to hearing about adverse events from others. Additionally, social media users may differ from the general US population treated with GLP-1 RA medications. However, more than 7 in 10 Americans use social media to engage with others, receive news, and share information, and the social media user base is increasingly becoming more representative of the broader US population [42]. As such, social media posts about GLP-1 RA medications may represent a combination of the experiences of the broader population taking these medications, those interested in taking these medications, or expressions of concern about these adverse events. They do not solely represent the adverse events reported by the subset of patients with type 2 diabetes or obesity who are prescribed these medications in clinical practice. Furthermore, for those taking medications, we do not know the dosage or the length of time that they were taking these medications. Thus, while social media posts cannot replace clinical trials or large cohort studies, they provide a meaningful, complementary data source to detect adverse events that may warrant further study. Furthermore, this study includes a subset of weight loss medications as identified from Facebook posts. Future studies can expand on this work to examine other drugs used for weight loss and investigate these questions using additional social media platforms. While the analyzed social media posts were in the English language and based in the United States, social media posts in other languages and from other countries can also be analyzed in the future to expand the scope and generalizability of the study's findings. To construct a list of potential adverse events, we used past literature, clinical expertise, and the SIDER database version 4.1 and did not use the subscription-based product, Medical Dictionary for Regulatory Activities [43]. It would be valuable for future studies to investigate the extent to which findings differ depending on approaches used to identify adverse events. While compounded versions of GLP-1 RAs are not FDA-approved and have been associated with significant adverse drug reactions, this study did not distinguish adverse events from FDA-approved GLP-1 RAs compared with compounded versions of GLP-1 RAs [31]. It would be valuable for future studies to examine differences in reported adverse events of FDA-approved and compounded versions of these drugs.

Conclusions

Social media provides a space for users to share personal experiences, challenges, and outcomes with weight loss medications in a way that is infeasible to ascertain from other data sources and study designs. Through our comprehensive analysis of Facebook posts during 2022 and 2024, we were able to systematically identify and characterize adverse event profiles attributed to GLP-1 RAs. Using advanced data filtering and extraction techniques, we were able to identify patterns and trends within these data to effectively highlight the unique role of social media in examining the public narrative about increasingly popular weight loss medications. As the rates of GLP-1 RA use continue to grow, it is imperative to investigate their short-term and long-term adverse events and user perceptions of adverse events associated with each drug, along with the complex relationships between concurrent adverse events. Overall, this study enhances our understanding of the nuanced perspectives of the therapeutic landscape, helping facilitate further discovery in this area.

Abstract

Background: Mental health organizations have the vital and difficult task of shaping public discourse and providing important information. Social media platforms such as X (formerly known as Twitter) serve as such communication channels, and analyzing organizational health information offers valuable insights into their guidance and linguistic patterns, which can enhance communication strategies for health campaigns and interventions. The findings inform strategies to enhance public engagement, trust, and the effectiveness of mental health messaging.

Objective: This study examines the predominant themes and linguistic characteristics of messages from mental health organizations, focusing on how these messages' structure information, engage audiences, and contribute to public information and discourse on mental health.

Methods: A computational content analysis was conducted to identify thematic clusters within messages from 17 unique mental health organizations, totaling 326,967 tweets and approximately 7.2 million words. In addition, Linguistic Inquiry and Word Count (LIWC) was used to analyze affective, social, and cognitive processes in messages with positive versus negative sentiment. Differences in sentiment were assessed using a Mann-Whitney *U* test.

Results: The analysis revealed that organizations predominantly emphasize themes related to community, well-being, and workplace mental health. Sentiment analysis indicated significant differences in affect ($P<.001$), social processes ($P<.001$), and cognitive processing ($P<.001$) between positive and negative messages, with effect sizes that were small to medium. Notably, while messages frequently conveyed positive sentiment and social engagement, there was a lower emphasis on cognitive processing, suggesting that more complex discussions about mental health challenges may be underrepresented.

Conclusions: Organizations use social media to promote engagement and support, often through positively valanced messages. Yet the limited emphasis on cognitive processing may indicate a gap in how organizations address more nuanced or complex mental health issues. Findings demonstrate the need for communication strategies that balance information with depth and clarity, ensuring that messages are trustworthy, actionable, and responsive to multiple mental health needs. By refining digital messaging strategies, organizations can enhance the effectiveness of health communication and improve engagement with mental health resources.

health communication; mental health; mental health organizations; computational analysis; LIWC; Linguistic Inquiry and Word Count; large scale data

Introduction

Background

Mental health conditions represent an urgent and escalating global public health crisis. The burden of mental illness is global, yet structural barriers, including underfunded resources and lack of access to care, persist across regions and economic contexts. The World Health Organization's (WHO) Comprehensive Mental Health Action Plan 2013‐2030 emphasizes the need for coordinated, scalable interventions, but a widening treatment gap remains, particularly in low-resource settings [1]. In this landscape, digital platforms serve as important places for mental health information, offering opportunities for intervention, advocacy, and public engagement at a scale typically unattainable through traditional health communication channels. Organizational structures play a vital role in shaping public discourse and mobilizing resources through social media [2-5]. They have the potential to facilitate large-scale mental health campaigns using health communication

XSL•FO
RenderX

strategies. As the global mental health crisis intensifies, it is critical to understand how organizations use digital platforms inform and build trust and ensure that mental health messaging is clear, accessible, and actionable.

Mental Health Organizations on Social Media

Health communication campaigns through advocacy strategies have been identified as a possibility for positive change for people experiencing these challenges [6]. The WHO called for key organizations to assist with mental health issue resolutions [7]. Similarly, the Center for Disease Control and Prevention put forth guidelines on health communication through text-based social media platforms like Facebook (Meta Platforms) or X (formerly known as Twitter) [8]. The importance of messages from such organizations has been examined in past research. Smith-Frigerio [6] examined 2 mental health advocacy groups' social media strategy. She found their messaging included awareness-raising strategies, support of various policy initiatives, and the promotion of diversity and inclusivity. Another study followed 3 mental health organizations' messages and engagement for a year and noted that content focused on mental health received more engagement as compared to relationship building or event promotion [9]. When investigating visual social media posts, Jia et al [10] noted that posts depicting knowledge about mental health disorders, their treatments, and antistigma frames were more heavily engaged content.

To better understand how mental health organizations communicate effectively, this study applies the Crisis and Emergency Risk Communication (CERC) framework to analyze the affective, social, and cognitive dimensions of their messaging. CERC helps organizations craft communication that enhances sensemaking and efficacy, ensuring messages are clear, actionable, and trustworthy. Traditionally used in public health crises [11,12], CERC is relevant to mental health communication, where strategic messaging can reduce stigma, build trust, and improve access to care [1,7]. This study extends CERC's application to social media, analyzing how mental health organizations engage with these principles in digital discourse.

Health Communication and Computational Text Analysis

A body of research has investigated the use of computational qualitative analysis in a broad range of disciplines, including health communication [12], psychology [13], tourism [14,15], physician education [5,16], and other domains. Importantly, we recognize there are advantages and disadvantages when using such approaches. Leximancer, for instance, was used [17] to strengthen the validity of their study of Indigenous voices in a public health curriculum. Gibson et al [18] examined a large volume of social media data regarding e-cigarette and tobacco coverage, using automated coding to content analyze the data. To generate reliability in the content analysis, they calculated the consistency of reliability for weekly estimates with a threshold set to >.70. Based on this, they found that X and YouTube (Alphabet Inc) contained fewer themes compared to other data sources. Vos and Buckner [11] examined an emerging crisis about the H7N9 virus and messages, drawing upon the CERC framework to address the ongoing communication that happened at various stages of the crisis. To analyze 25,598 unique messages, automated coding was used to identify sensemaking and efficacy messages in messages.

Social media sites can have a profound effect on communication regarding mental health, but there remains a dearth of knowledge on the detection of concepts and themes in a larger corpus of mental health discourse, especially from the perspective of official organizations, though this technique has been used in other fields, such as digital entrepreneurship [19,20]. Likewise, the application of Leximancer to health issues research is recent. There is a compelling opportunity for scholars to use automated text analysis to examine health-related data, especially when other approaches cannot process the volume of data. Considering this, automated data analysis to quickly understand the corpus of large amounts of words and text in data can be useful in health research, although it is not a panacea for understanding phenomena [21].

In prior research, these approaches have been used to explore larger data sets and mental health but have yet to fully emerge in health communication-related research, though they have been explained using interpretivist approaches from survey data with larger response rates (n=934; [22]). Other studies [23] investigated the environmental effects of COVID-19 using Leximancer. They first used a segmented regression technique and then applied automated content analysis on environment-related subreddits to gain insight into the evolution of risk amplification and ripple effects. In this study, Leximancer was used to demonstrate how large data sets may be used in qualitative research in the context of health communication, specifically in nuanced communication through mental health. The capabilities regarding automated textual analysis and interactive, visual depictions of the relationships among the data have long been highlighted as important for extracting the meaning of themes. Examining the predominant themes in mental health communication can yield important insights into the issues and challenges organizations face in disseminating and ultimately reaching the public.

The following research question is offered:

Research question 1 (RQ1): What are the most prevalent themes present in messages about mental health led by mental health organizations?

Message Sentiment

Linguistic features are integral to shaping the themes expressed in communication, which is an inherently complex process. As a fundamental component of communication, language influences how messages are interpreted and significantly impacts psychological health [24]. Linguistic Inquiry and Word Count (LIWC) has long been used in research to understand cognitive complexities in language use and texts, including social media data, and in relation to mental health. Research has indicated that depressed patients have been more likely to use negative emotion words and express more self-focused thoughts [25], while the use of types of words, such as causation words and self-discrepancies, have been linked to positive health outcomes [26]. Therefore, to analyze language use in the messages from mental health organizations in terms of their

XSL•FO
RenderX

affect, social, and cognitive processes using LIWC, this research adds deeper value into the study of the relationship between mental health and communication. A total of 3 fundamental processes are analyzed: affect (emotional contents of language), social (process of interactions with others), and cognitive processes (how information is processed and language regarding insights, causation, and discrepancies).

Social media platforms serve as key sources of mental health information, offering vital insights into how organizations communicate and engage the public. Researchers have increasingly used LIWC to analyze mental health–related content on X, examining linguistic patterns and their role in shaping information delivery. This study explores how mental health organizations structure their messaging within a large text corpus. Based on this, we propose the following hypothesis (H1):messages from mental health organizations will vary such that those with positive sentiments will have significant differences in affect, social, and cognitive processes compared to those with negative sentiments.

Methods

Data Collection

Tweets from mental health care organizations were collected using the Twitter API using March 2023 as a deliberate sampling frame due to the data size and scope. The organizations were identified through a snowball sampling approach, which began with accounts that were reshared or followed by a population of relevant accounts. The goal was to compile a list of accounts explicitly focused on mental health promotion or services or for which mental health was a core organizational value. Queries were conducted using organization names and their common abbreviations with specific parameters (eg, NIMHgov for the National Institutes of Mental Health), following methods of previous studies [27]. The initial sample included accounts reshared or followed by relevant organizations, and the iterative nature of the snowball sampling allowed the sample to expand gradually. This process resulted in a final dataset of 17 unique accounts queried. The dataset includes 326,967 tweets from 17 unique mental health organizations (see Multimedia Appendix 1). This dataset consists solely of tweets originally posted by these organizations and does not include mentions, replies, or retweets from other users. Account-level metadata, such as follower count and creation date, was not collected as part of the extraction process and is not available for analysis. Sampling procedures and account inclusion criteria were consistent with established scholarship [27]. Multimedia Appendix 1 provides a list of the accounts, including their X handles, full names, and the number of messages they posted at the time of data collection.

Data were extracted from JSON files and saved as a CSV file to facilitate analysis and ensure alignment with the study's focus on mental health communication. The dataset included details such as the text of each post, post type (eg, social media engagement metrics such as likes, quote counts, replies, and retweets), timestamp, and number of impressions. To assess the extent of irrelevant content, a review was conducted on a randomly selected 10% (32,900) subset of tweets. Following this review, thematic extraction was refined using Leximancer's automated procedures. To minimize data noise, the thematic relevance threshold was adjusted to retain only central, frequently co-occurring concepts in the final analysis. Concepts with weak connectivity, such as isolated fundraising messages, promotional event announcements, or generic engagement phrases ("join us" or "support this"), were ranked lower and excluded from core thematic groupings. Leximancer identified thematic clusters through semantic co-occurrence analysis, assigning prominence scores using a color-coded red, green, and blue (RGB) scale. Concepts most frequently appearing in central discourse were highlighted in hotter colors (red, orange, and yellow), while less prominent or potentially irrelevant content was represented in cooler colors (green, blue, and violet).

Ethical Considerations

We were mindful in our use of publicly available social media data, particularly given the ethical complexities surrounding mental health content. Ethical standards in this area are still evolving, and while many users may have awareness that their data can be accessed under terms and conditions, the extent of that understanding likely varies considerably [28,29]. We removed any potentially identifying information from the dataset, and usernames and IDs were not included in the queried API. As a result, the dataset only consisted of the aforementioned information, and no personally identifying information was included in the data analysis. We recognized that some groups may be either under- or overrepresented when analyzing the themes and sentiment in a larger scale analysis, and in addressing a stigmatized health issue [30]. We were cognizant of the potential harms and risks and sought to be mindful of these in the analysis by analyzing only text contents and excluding any user IDs or potentially identifying information.

Data Analysis

RQ1 was analyzed using Leximancer, an automated machine learning software that identifies thematic clusters without requiring predefined coding categories. Leximancer detects co-occurring terms within a dataset, using semantic relationships rather than word frequency alone to reveal conceptually connected themes [31]. This approach enables researchers to analyze patterns in large text corpora by grouping related ideas based on their contextual associations. While Leximancer generates data visualizations that organize key concepts into thematic clusters, researcher interpretation remains essential [3,13]. In these visualizations, themes are named based on the most prominent concept within each cluster, and researchers can refine these labels by reviewing associated terms. The strength of each concept is visually represented through a color gradient, ranging from red (most prominent) to violet (least prominent), reflecting its frequency and relevance within the data set.

Concept maps were generated using Leximancer to identify key topics emerging from the messages. Standard semantic and relational extraction techniques were applied. In the semantic extraction phase, the software identified fundamental concepts, terms that frequently appear together, by analyzing their

XSL•FO
RenderX

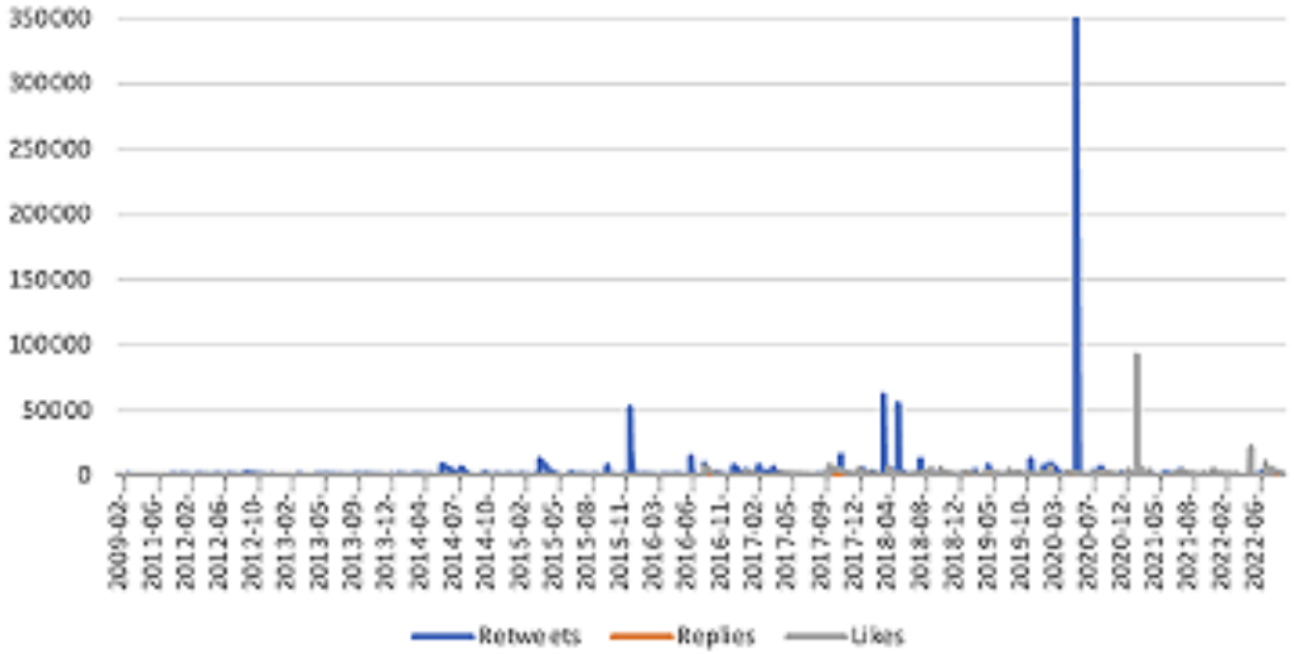
frequency, occurrence, and co-occurrence. These concepts were then weighted and placed in a co-occurrence matrix, with a thesaurus of highly relevant words and phrases generated to refine semantic meaning [32]. In the relational extraction phase, the discovered concepts were analyzed to determine their associations. After computing concept count, co-occurrence frequency, and relative importance, a data visualization was created. This visualization prioritizes highly co-occurring concepts, clustering them into themes based on their strongest connections.

To address H1, LIWC was used to measure the emotional tone of messages made, comprising roughly 7.2 million words and the full 326,967 tweets. We computed the mean score, SD, skewness, and kurtosis for each dimension of affect (mean 0.111, SD 0.079; skewness=1.516, kurtosis=5.171), social (mean 0.1752, SD 0.1055; skewness=0.973, kurtosis=1.838), and cognitive (mean 0.094, SD 0.077; skewness=0.914, kurtosis=1.374). Out of each of the dimensions, the distribution of affect scores was found to be significantly left-skewed ($z=-250.589$; $P<.001$), indicating that most mental health organizational messages with negative sentiment held higher affect scores compared to those with positive sentiment. Likewise, because messages were made by distinct mental health organizations and presumably different users (thus treating cases as independent observations), a Mann-Whitney *U* test was conducted.

Results

Overview

The findings are presented by first addressing the results of RQ1, followed by H1. RQ1 focused on identifying the most prevalent themes in messages about mental health shared by mental health organizations. The concept map output, which considers the dataset regardless of the date or time of messages, revealed a y-shaped structure with 2 distinct paths, where the left path is slightly more prominent than the right. Figure 1 shows the concept map. Following recommendations for conducting research with Leximancer [32], we identified the dominant concepts within these clusters as themes, including example messages were relevant. Leximancer identified thematic clusters based on semantic co-occurrence patterns in the dataset. The most prominent themes, community, mental health, and well-being, emerged without predefined coding categories. These themes were later interpreted through the lens of CERC, which emphasizes trust-building, efficacy, and social support. While Leximancer does not apply theoretical labels, the resulting themes align with CERC principles, reinforcing its relevance to digital mental health messaging and are later included in the discussion.



XSL•FO
RenderX

Figure 1. Concept map of the data.

XSL•FO
RenderX

A time series analysis further highlights the evolution of engagement with the message data (Figure 2). The y-axis represents the total number of engagements, including likes, retweets, and replies, while the x-axis denotes the date and time of posts. This analysis illustrates how engagement fluctuated over time, with periods of heightened activity aligning with significant mental health-related events. For example, the largest spike in activity occurred in March 2020, marked by a surge in retweets, coinciding with the WHO's declaration of COVID-19 as a global pandemic.

Figure 2. Temporal engagement over time with mental health messages.

RQ1 Findings

The most prominent thematic cluster identified was community, followed by mental health and well-being. The first 2 clusters demonstrated a linear relationship, where topics associated with community were directly linked to mental health, without further connections to other themes in the concept map. In contrast, the discourse surrounding mental health extended to less prominent, peripheral themes such as depression. Although these themes were less centralized, they held notable importance within the overall communication landscape. For example, some messages highlighted calls to action, such as: "What are you doing for your mental health this holiday season?" Posts such as these were often accompanied by links to resources promoting self-care and mental health practices, encouraging individual engagement with mental health management.

While well-being was not the most dominant theme, it served as a crucial connecting point in the y-shaped conceptual structure, bridging otherwise distinct clusters. The theme of well-being acted as a connecting point, linking concepts such as feelings, social support, and Twitter users. This indicates that mental health organizations strategically promoted prosocial messaging aimed at fostering shared communication and engagement. Many messages sought to directly interact with audiences through participatory activities, such as fundraising initiatives or encouraging retweets. In some cases, these messages attempted to challenge public perceptions of mental illness, as illustrated by posts like: "What does mental illness look like to you? [...] Send yours to [fundraising, redacted]." In addition, organizations shared practical resources designed to assist individuals in need, including helplines and support services. For instance, messages advertised emotional support systems: "Mentalhealth helpline offering specialist emotional support, guidance, and information" and "Textcare provides emotional support and connection when you need it most."

In the concept map's right-side path, less prominent themes emerged, including workplace and employees. These themes illustrated the role of work environments in shaping mental health and well-being, with organizations sharing messages emphasizing the importance of supportive workplace cultures. For example:

> *Organisational culture is critical to #wellbeing in the #workplace" linked to reports outlining strategies for fostering mental health in professional settings. Similarly, some messages underscored the value of positive work environments with messages such as, "Creating a great work environment matters. #healthyworkplace.*

Although themes on the periphery of the concept map, such as employee were ranked as less prominent, they provided meaningful insights into specific facets of the discussion. For example, the employee cluster included terms like "GPTW" (Great Place to Work), which may strengthen messaging about workplace mental health. These findings suggest that peripheral themes, while less frequent, often enrich the central discourse by adding nuanced perspectives and addressing less commonly explored areas.

These thematic clusters reflect a comprehensive strategy by mental health organizations to engage diverse audiences. Dominant themes serve as anchors, while secondary and peripheral themes act as bridges, connecting audiences to

XSL•FO
RenderX

lesser-explored topics. These layered insights not only enhance the understanding of mental health communication but also highlight opportunities for expanding outreach and improving messaging strategies. The implications of these findings are explored further in the discussion.

H1 Results

H1 examined whether there would be a significant difference in emotional processes in mental health organizational messages with positive sentiment compared to negative sentiment. LIWC was used to measure sentiment-related linguistic features, including affect, social, and cognitive processes. This analysis was conducted independently of Leximancer and was not used to categorize themes. A Mann Whitney-*U* test was performed, which showed significant differences in affect (U=6.582E+9, z=−250.589; P<.001), social processes (U=7.582E+9, z=−213.367; P<.001), and cognitive processes (U=1.275E+10, z=−21.660; P<.001) between mental health messages with positive sentiment compared to those with negative sentiment. The effect sizes for these differences were small (cognitive: r=−.205) to medium (affect: r=−.556, social: r=−.469).

These results suggest that the mean rank of messages containing negative tone were altogether lower than mean rankings of messages that were positive in tone. Thus, although the negative effect sizes suggest that each of affect, social, and cognitive dimensions held lower means, the values were highly statistically significant. Therefore, we suggest the results may support H1, which predicted differences in each of these processes in the emotional tone in messages.

Discussion

Principal Findings

Effective health communication goes beyond simply raising awareness; it requires transparency, credibility, and a commitment to delivering high-quality health information that resonates across different populations. This study underscores the essential role of health communication in shaping public perceptions of mental health and ensuring that information shared by organizations is accessible, trustworthy, and actionable. These findings highlight how mental health organizations use social media to frame information around well-being, but they also reveal gaps in addressing structural barriers to care and the need for more nuanced engagement strategies.

The analysis reveals that mental health organizations primarily emphasize community, well-being, and support networks in their messaging. While these themes foster positive engagement, there is a pressing need for clearer, more actionable communication strategies that go beyond broad encouragement to provide concrete guidance. Effective messaging must acknowledge the complexities of mental health struggles, offer practical pathways to care, and address the nuances of different lived experiences. Trust remains central to mental health communication, and organizations must ensure their messaging is both scientifically accurate and culturally responsive to reach audiences effectively.

Regarding H1, the linguistic analysis further underscores the role of emotion and social connection in digital mental health messaging. Findings indicate that while positive sentiment is a dominant strategy, it may not always align with the lived experiences of individuals facing mental health challenges. Overly optimistic framing, while engaging, could inadvertently dismiss the complexity of mental health struggles, or discourage open conversations about distress. A balance is needed: one that promotes hope while validating the realities of mental health needs. Health communication efforts must consider how organizations can refine their language to be impactful, ensuring that health information is framed in ways that build trust, encourage help-seeking, and reduce stigma.

These findings align with the CERC framework, which emphasizes that effective health communication should engage and provide clear, actionable information that enables individuals to respond to their circumstances [11,12]. While organizations successfully foster social connection, many messages lack the informational clarity and efficacy-building components that CERC underscores as essential in public health communication. Without concrete guidance, audiences may struggle to translate engagement into action. Applying informed strategies, such as reinforcing practical coping strategies, clear pathways to care, and guidance on recognizing and addressing mental health concerns, can help organizations move beyond awareness-building toward delivering information that empower individuals to take meaningful steps in managing their health.

Mental health communication takes place globally on social media platforms, with differing social and cultural contexts that shape how messages are received and interpreted [33]. As mental health organizations engage with global audiences, understanding how language functions across affective, social, and cognitive dimensions [34] are essential for researchers and practitioners. However, while fostering a positive emotional tone can enhance engagement, it is equally important to recognize that cultural variations in emotional expression and information shared may lead to unintended consequences. Overemphasizing positivity may inadvertently invalidate negative emotions, reinforcing stigma or limiting dialogue about health struggles, particularly in areas where stigmatization is an issue. To maximize impact, organizations must ensure that their messaging is culturally responsive, contextually appropriate, and globally inclusive of lived experiences.

By identifying key themes and emotional tones that effectively engage audiences, researchers can guide the development of evidence-based communication strategies for mental health organizations [10,35]. The study's use of computational analysis alongside LIWC demonstrates a scalable approach to analyzing social media data, offering insights that extend beyond mental health to broader health communication. These findings provide organizations with actionable strategies to craft messages that are informative and impactful, ensuring they resonate with audiences encourage engagement.

These results highlight the important role of language in shaping mental health communication through information shared on social media, particularly the impact of positive sentiment on affective and social processes. The lower cognitive processing

XSL•FO
RenderX

scores observed in mental health-related messages suggest that individuals facing mental health challenges may find it difficult to engage in complicated reasoning or articulate their experiences fully. This has important implications for organizations aiming to craft messages that are both accessible and solutions oriented. Rather than relying solely on positivity, messaging should balance encouragement with clarity, offering tangible strategies that individuals can apply to maintain or restore wellness. Findings from H1 reinforce the need for a deeper understanding of how language influences engagement with mental health communication on social media. A more nuanced approach to message design, grounded in both scientific accuracy and sensitivity to lived experiences, can enhance the effectiveness of mental health discourse, ensuring it supports those who need it most.

Limitations and Future Directions

This study examined overarching thematic patterns in mental health communication across organizations, rather than stratifying by account type. While differences in messaging strategies may exist between government agencies, advocacy groups, and service providers, our analysis was designed to capture broad trends rather than organizational distinctions. Future research could explore these variations by applying stratified thematic analysis. This study builds on previous scholarship while recognizing its potential limitations [36].

A limitation of this study is that themes were analyzed at the aggregate level without stratifying by organization type. Future research could examine whether certain themes are more prominent among different categories of mental health organizations, providing additional insights into institutional messaging strategies. Using X as a data source means that the sample reflects conversations from a public stream, which may introduce biases based on the users who actively participate on the platform [36]. Automated sentiment analysis, while valuable, has inherent limitations in capturing the full nuance and complexity of human emotions. Although emotional tone can be quantitatively measured, it may not fully account for the range of interpretations and contextual meanings in messages. Furthermore, snowball sampling was used to identify relevant accounts by tracking those frequently retweeted or followed. This method ensured consistency in the dataset but may have led to overrepresentation of highly visible accounts, potentially overlooking lesser-known organizations and users. Social media research also faces broader challenges, as the nature of online information and messages varies across platforms. Differences in audience demographics, communication styles, and modes of expression highlight the importance of comparing discussions across multiple platforms to better understand the specific contexts in which these conversations take place.

Analyzing large-scale social media data presents several challenges. Researchers must navigate high data volumes, the evolving nature of digital texts, user behaviors, data legitimacy, and ethical considerations when handling sensitive content [28,29]. Future research can build on these findings by exploring how emotional tone and language use in mental health organizations' messaging influence health literacy, attitudes, beliefs, and behaviors.

Conclusions

This study investigates how mental health organizations leverage social media to shape public discourse, focusing on the themes and linguistic strategies that define their messaging and information shared. The findings reveal that these organizations primarily emphasize community, positive sentiment, and workplace-related discussions on well-being. Health communication plays a crucial role in shaping public understanding and engagement, the clarity, accessibility, and trustworthiness of these messages are essential. Effective communication not only informs but also empowers individuals by providing actionable, evidence-based information. By analyzing these digital messages and the information shared, this study contributes to a deeper understanding of how mental health is framed on social media, offering insights into how messaging strategies can be refined to enhance public trust, reduce stigma, and promote meaningful engagement with mental health information.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

RKI served as the lead author and contributed to the study design, data collection, data analysis, and leading stages of manuscript development, including drafting, writing, and revisions. AR contributed to the development of the literature review, supported insights on the data analysis, and provided critical feedback on manuscript drafts. SK assisted with the literature review, contributed to the insights on the methodological framework, and offered insights into the study design. HJC provided input on the introduction, helped reshape the literature review and conceptual framing of the arguments, and provided substantive input on the Discussion and Conclusion sections.

Conflicts of Interest

None declared.

Abstract

Background: While the negative effects of postpartum depression on maternal-infant bonding are well-documented, our understanding of how it exerts these effects remains incomplete. A better understanding of how maternal postpartum depression affects bonding can enable clinicians to better identify and support mothers with difficulties bonding with their children.

Objective: This study aims to describe the bonding experiences of mothers with postpartum depression through an analysis of short-form videos and user engagement.

Methods: We collected publicly available highly-viewed TikTok videos using hashtags associated with postpartum depression and associated engagement metrics in May 2023. After manual screening, we extracted 533 videos related to the mother-infant bond, from which we analyzed a random subset of 159 videos. We abstracted categories from videos using a hybrid deductive and inductive approach. Negative binomial regression models of video likes, views, shares, and comment count were used with content categories and the creator's numbers of followers as independent variables.

Results: Abstraction of content from mother-infant bond videos resulted in six categories: (1) navigating anxiety and anger, (2) creating physical and emotional boundaries, (3) overwhelmed by demands of caregiving, (4) subverted expectations, (5) enduring and finding strength through the challenge of postpartum depression, and (6) can't remember early life. Subverted expectations and navigating anxiety and anger categories were associated with increased views (rate ratio [RR] 1.72, 95% CI 1.22 - 2.43; RR 1.61, 95% CI 1.09 - 2.38, respectively), likes (RR 3.61, 95% CI 2.55 - 5.11; RR 3.96, 95% CI 2.69 - 5.85, respectively), shares (RR 2.95, 95%CI 2.09 - 4.18; RR 2.45, 95% CI 1.66 - 3.61, respectively), and comments (RR 2.78, 95% CI 1.97 - 3.94; RR 1.89, 95% CI 1.28 - 2.79, respectively). Sensitivity analysis with creators with fewer followers mostly aligned with these results.

Conclusions: This qualitative content analysis of short-form videos identified specific ways postpartum depression impacts the mother-infant bond, highlighting strategies for clinicians to support bonding. Analysis of engagement metrics further demonstrated the types of experiences that most resonate with viewers. Our findings demonstrate the potential of this qualitative method to augment understanding of lived experiences.

KEYWORDS

postpartum depression; perinatal depression; postpartum anxiety; depression; TikTok; social media; video; content; postpartum; anxiety; maternal-infant; qualitative; content analysis; bonding; experience; deductive; inductive; regression model

Introduction

A mother's bond to her child in the first few years of life greatly influences the child's development and future mental health. The bond is a caregiver's emotions, cognitions (ie, thoughts and beliefs), and behaviors toward the infant [1,2]. Bonding promotes child development, including physical, cognitive, and socioemotional domains [3-5], with more potent effects for the latter postnatally [3-7]. Longitudinally, stronger postpartum bonding is associated with less child internalizing and externalizing problems [6-8].

While the negative effects of poor maternal-infant bonding (MIB) are well-documented, our understanding of bonding, particularly in the context of depression, is lacking. Postpartum depression afflicts at least 13% of all birthing mothers annually in the United States and can harm child development and mental health in part by impairing mother-child bonding [7,9]. Yet, recent studies on the operationalization of the MIB find the construct, content, and structural validity of MIB measures,

XSL•FO
RenderX

including measures validated in women with postpartum depression, to be insufficient [10,11]. A lack of diverse samples in measurement development may contribute to this issue [11]. Most qualitative studies focus on maternal depression more broadly rather than the MIB in mothers with depression. Such studies could provide valuable insights about the MIB in the context of postpartum depression [12]. A better understanding of how postpartum depression exerts this effect can help clinicians identify and support mothers with difficulties bonding with their children.

One way to increase understanding of MIB is to examine the experiences of women with postpartum depression, as described on social media. With the rise of social media, mothers have taken to the internet to discuss mental health difficulties using a variety of platform types (blogs, microblogs, forums, photo sharing, etc). Women share experiences of their own accord, allowing for the concerns of those with lived experiences of postpartum depression to come to light. Understanding these experiences is crucial as social approval, fear of judgment, or fear of having their child removed may make women less likely to disclose their concerns to clinicians [13]. Existing studies primarily use text-based social media such as forums [14-18]. To our knowledge, no studies to date have used video-based social media to examine MIB in the context of postpartum depression. Video-based social media data can provide a detailed understanding of the experiences of women with postpartum depression as compared to text alone, capturing nonverbal communication and additional contextual factors. TikTok, a social media platform featuring short-form videos, has significantly higher use (over 1 billion monthly active users) [19] than text-based platforms used in prior studies, potentially allowing for more diverse perspectives and broader reach.

Therefore, this study aims to categorize common ways mothers endorsing postpartum depression describe their bond with their child using content analysis of highly accessed videos on TikTok. In addition, this research examines user engagement (ie, views, likes, comments, and shares) across these categories.

Methods

Overview

We conducted a qualitative content analysis of videos from TikTok to document the variety of experiences of bonding in mothers with postpartum depression. Our approach was hybrid in nature, combining data-driven coding with literature-based coding [20]. The study followed the Standards for Reporting Qualitative Research reporting guideline [21].

Ethical Considerations

The University of California, Los Angeles Institutional Review Board (#23-001157) deemed this nonhuman participant research exempt. Although we used publicly available data, given reidentification risks, we deidentified data throughout the study by not using identifiable information. Furthermore, we do not provide hashtags used for this study.

Data Collection and Preprocessing

We identified videos using hashtags associated with postpartum depression, a common method in social media studies [22]. Content creators' use of these hashtags suggests that they may self-identify with this diagnosis or its symptoms. Specific hashtags were identified using a variety of sources. First, the term "postpartum depression" was searched using the TikTok search feature. Common hashtags used in the initial 20 videos were collected. In addition, hashtags for postpartum depression that were used in other social media studies were evaluated [15]. We chose the 3 hashtags with the most views. Using these hashtags, we used the app Apify in May 2023 to collect publicly available popular videos and associated engagement metrics. These hashtags had a combined 1.1 billion views when videos were collected in May 2023.

We manually reviewed videos to exclude videos without content related to postpartum depression, and subsequently, not related to the mother-infant bond. We also excluded videos that were not in English, although the speakers were not required to be native English speakers. Given the large number of relevant videos (n=533) and resource constraints, we decided to use a random sample of approximately a third of the total number of videos collected (159/533, 30%) for analysis. This number of videos is in line with other content analysis studies of TikTok, which examine between 25 and 150 videos [23-26].

Engagement Metrics

To explore user engagement with videos, we examined video views, likes, shares, and comments. Views indicate how many people were exposed to the content. The number of likes shows how many people responded positively to a video by endorsing it. Shares capture the number of times users spread the video to their network, indicating how much it spread beyond the original audience. A high share count suggests that a video garnered enough interest to be actively passed on. The number of comments reflects how much discussion the video generates by prompting reactions and opinions from viewers.

Content Analysis

The research team consisted of a male psychiatrist with experience working with mothers with postpartum depression and infant mental health, along with a female medical student and a female undergraduate student who are interested in obstetrics and child development and psychology, respectively (KS, JSC, and SYZ).

A coding rubric was developed in several stages using an inductive and deductive (ie, hybrid) approach [27,28]. Videos were the unit of analysis with visual, audio, and text (both in the video and its description) components. First, deductively, one author (KS) identified an initial set of codes based on existing literature to design a preliminary codebook. Subsequently, over 5 rounds, coders independently watched 45 videos (5 - 10 per round) from the eligible videos and then reviewed them as a group. In initial rounds, coders gained familiarity with videos and determined the validity of the initial set of codes. Discrepancies in coding were discussed and resolved as a group. Furthermore, inductively, we added a new preliminary code whenever a video featured an experience of

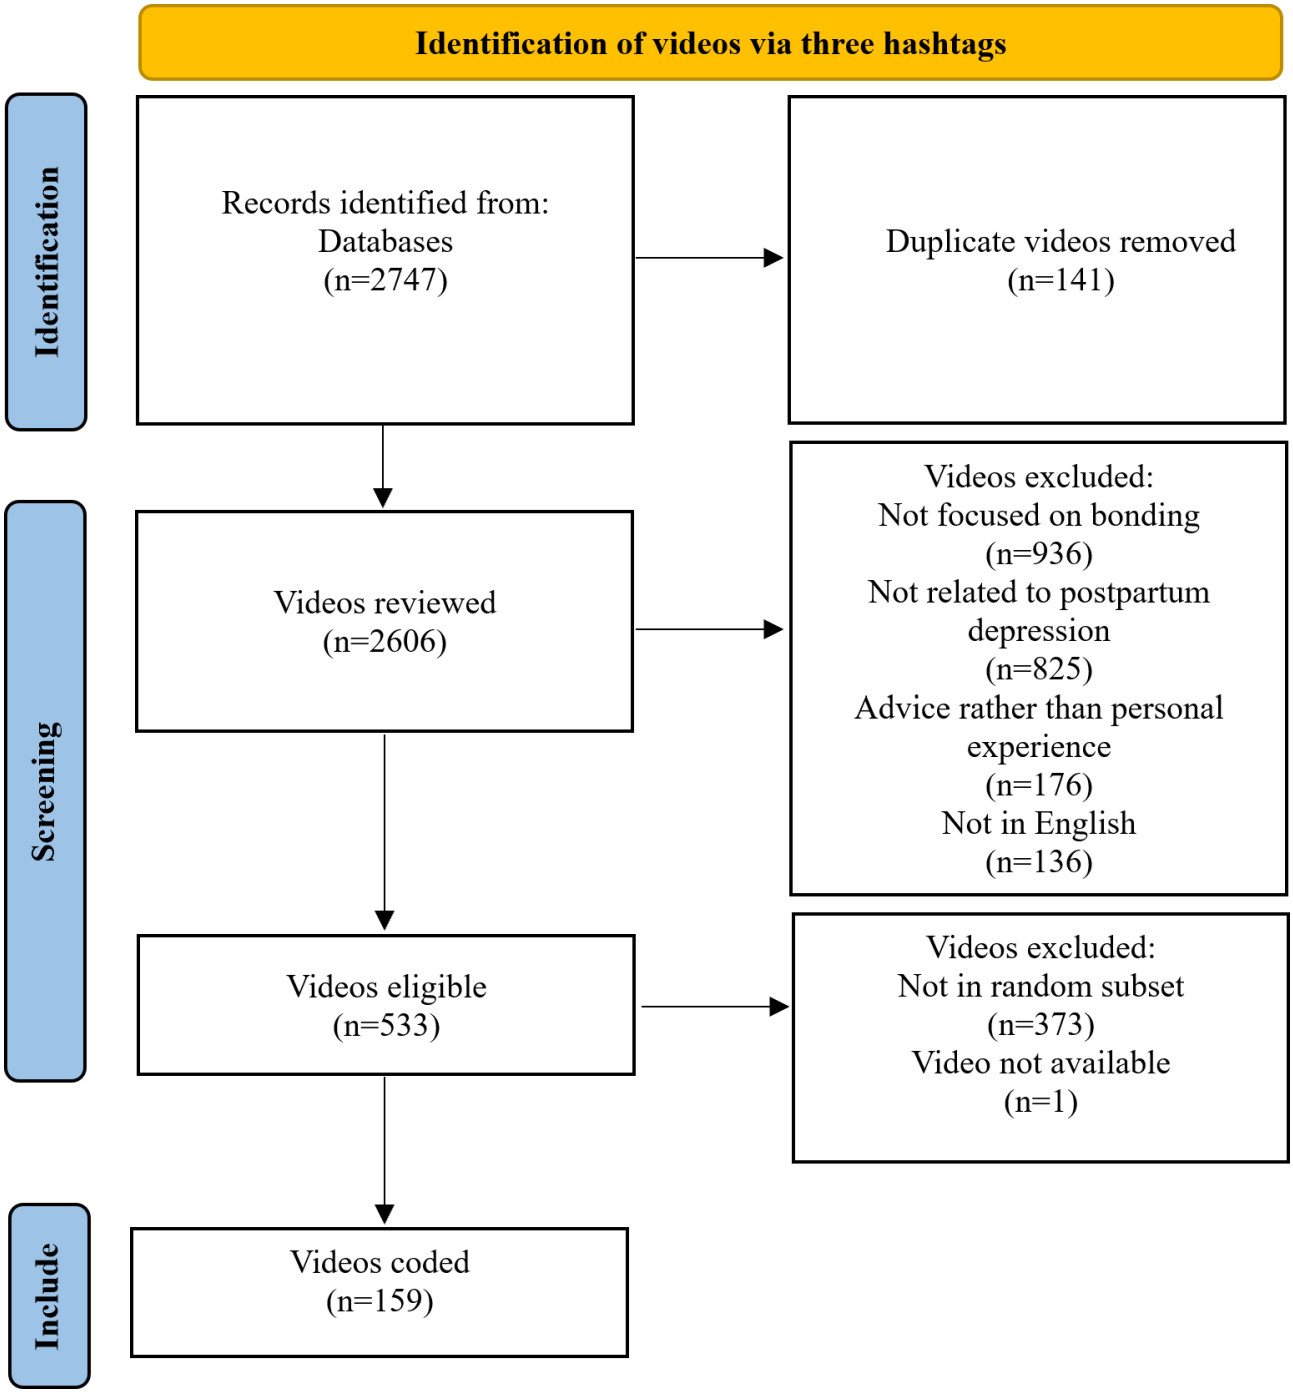
XSL•FO
RenderX

the MIB that could not be suitably coded into any existing categories. Bonding experience codes that frequently recurred were made into permanent codes. We reached data saturation finding repetition of codes during our coding of our final random sample of 159 videos. Code definitions are provided in Table S1 in Multimedia Appendix 1 with codes derived from the literature cited. Videos were coded under multiple codes when applicable. Interrater reliability (IRR) was acceptable (Krippendorff α=0.67 - 0.71) [29] in pairwise ratings of coders for coding 30 randomly selected videos. We used Excel (Microsoft Corp) to facilitate coding.

Our data abstraction from codes to categories was guided by the nature of the data and our research objectives [30]. Given the short-form nature of many TikTok videos with limited depth and our desire to closely represent the postpartum depressed mothers' bonding experiences, we abstracted from codes to a higher-order category grouping without much interpretation. Thus, we chose not to use a thematic framework to avoid imposing external structures on the data. Instead, we used Miro boards to independently sort and group codes into categories based on similarities and relationships between codes. Categories had to be internally homogeneous and distinguishable from other categories. We then compared independently created categories among coders and aligned them to finalize the categories.

We reviewed creators' profiles and videos to determine their country of residence and the approximate age of their child when the mothers experienced postpartum depression. To estimate the child's age, we primarily used the age of the child when the video was created. However, if the mothers specifically mentioned experiencing depression during a particular period, such as the "first few months," we used that age instead.

Statistical Analysis



Because engagement metrics were skewed, we fit a negative binomial regression. Our dependent variables included likes, views, shares, and comment counts. The independent variables were the categories of video content. We also included the content creator's number of followers (log-scaled to account for overdispersion) as an explanatory variable because it is generally associated with video engagement. We included all independent variables simultaneously (ie, no stepwise regression) in the model. We used Python (version 3.8.8; Python Software Foundation) for data analysis. Statistical tests were 2-sided with significance set at $P<.05$.

Results

Figure 1 outlines the review process that resulted in 533 relevant videos.

XSL•FO
RenderX

Figure 1. Flow diagram of included videos.

Characteristics of the Included Short-Form Videos

The 159 videos from 147 content creators in our analytic sample had a median of 42,200 (IQR 10,800 - 15,6750) views, 4347 (IQR 970-12,100) likes, 35 (IQR 5-196) shares, and 80 (IQR 26-365) comments. Altogether, these videos have been viewed over 35 million times. Video creators (n=147) had a median of 31,800 (IQR 5265 - 137,900) followers ranging from 46 to over 1,700,000. Creators were primarily based in the United States (141/159, 88%). Other countries represented included the United Kingdom (7/159, 4%), Canada (5/159, 3%), Australia (2/159, 1%), South Africa (1/159, 1%), the Philippines (1/159, 1%), and New Zealand (1/159, 1%). The country of one creator could not be determined (1/159, 1%). Most mothers experienced postpartum depression during the first year of their child's life (147/159, 82%). Mothers of toddlers, most of whom had children younger than 2 years of age, were also represented (17/147, 12%). In some cases, the age of the children could not be determined (9/147, 6%).

Content Categories

Overview

We abstracted 6 categories from the video codes, which are described below. Table 1 lists categories with their respective codes and examples.

XSL•FO
RenderX

Table . Categories with code examples of the content of depressed mothers' bond with their child.

Category, code	Example video description
Navigating anxiety and anger	
Obsessive thoughts or worries about the child's health or safety and compulsive behaviors to cope with it	The video shows a mother enacting an internal argument with her brain regarding her child's safety when a family member holds the baby. Her brain worries that another family member will drop her baby and wants to take the baby back. Despite the creator trying to rationalize that the baby is safe in an effort to quell her intrusive thoughts, she feels a panic attack beginning.
Obsessive thoughts or worries of harming the baby and compulsive behaviors to cope with it	The creator was visibly upset as she shared ego-dystonic intrusive thoughts of harming her baby in the first few months postpartum. These included thoughts of dropping her baby. She could not control these thoughts, resulting in her having panic attacks and needing another person to stay with her. She reports being afraid to tell people, including her husband, but eventually, she did open up to her obstetrician.
Feelings of anger or aggression toward the child	The video shows a mother holding her head as she seems to reminisce. Text overlaid on the video describes a memory of wanting to throw her baby across the room when rocking the baby to sleep. But instead, she threw a piece of exercise equipment. Mother mouths "crazy" along with the lyrics from a song playing.
Involuntary emotional or mental responses	Video of mother verbally describing her postpartum depression relapse. She reports crying whenever she sees her child for no apparent reason. She starts tearing up after changing the camera angle from herself to show her baby.
Creating physical and emotional boundaries	
Mothers put up physical or emotional boundaries for fear of harming the baby	The creator stares at the camera as it zooms in with text overlaid on the video. Text relays an instance when she was in distress, waiting in the closet for a relative to come so she could avoid hitting her child. Music plays in the background.
Mothers put up physical or emotional boundaries for relief	The creator states that it is okay for moms to want to hide and get a break. Music in the background has lyrics about needing "me time" and "free time."
Mothers try to minimize their child's exposure to their distress or hope it does not or did not cause distress	The video shows a mother who appears to be putting the final touches on her appearance with text that she puts on a happy face for her baby despite going through postpartum depression and wanting to "curl in a ball and sleep."
Overstimulated by too much sensory input from the child	The mother mentions that hearing her child cry causes her physical pain and agony.
Escaping from the caregiving role	Mother is tearful with overlaid text that she could never understand how people could leave their children behind until she had postpartum depression.
Overwhelmed by demands of caregiving	
Overwhelmed by caregiving responsibilities	The video shows a mother initially smiling but then gazing into the distance, thinking about something deeply. As she thinks, text bubbles appear and pile up on one another. These thoughts state things like: "What if she falls?"; "laundry"; "My house is a mess"; and "I shouldn't have yelled." Among the many thoughts piling up are: "I can't keep this up" and "Am I a good mom?"
Depression makes it difficult for the mother to take care of their child	The video shows a mother's internal struggle with her feelings of depression and lack of motivation to get off the couch to care for her child, as well as feelings of guilt about being an incompetent mother. Mother shares the thoughts racing in her mind, such as: "You're a bad mom for not playing with him."
Breastfeeding as a burdensome and distressing experience	The video shows a mother with a can of formula with the text: "I'm not okay. I bought a can of formula last night because I'm so burnt out over nursing." Mother covers her face with her hands near the end of the video as if exhausted or ashamed with text that she "feel[s] like a failure for quitting."

XSL•FO
RenderX

Category, code	Example video description
Not feeling the expected emotional connection or enjoyment with the child	The mother uses sound bite, saying, "This is how it feels?!" to express her surprise after finally feeling a strong connection to her child after struggling with postpartum depression (written in text).
Subverted expectations	
Feelings of guilt or regret regarding their care or relationship with their child	The video shows a montage of videos of the creator's child as a newborn. In the video text, she expresses regret that she could not cherish her child's newborn phase because she was overtired and overwhelmed.
Feel incompetent as a mother	The video shows a mother on one side of a door embracing her child with text that she is trying to be a good mom. On the other side of the door, she personifies postpartum depression, trying to break through the door to disrupt the mother's efforts.
Enduring and finding strength through the challenge of postpartum depression	
Mother finds hope or resilience through their relationship with their child	The video shows a collage of photos of a mother and baby appearing happy. The text says: "Postpartum was not good to me, but she is the sole reason I'm still here and always will be."
Responsibility or duty to the child	The video has narration stating difficulty getting out of bed but having to do so "to keep them [children] alive." The video goes on to say that although the mother feels like she is "hanging on by a thread," she continues to get up each day for her children.
Positive feelings or thoughts toward the child or a positive relationship with the child despite postpartum depression	The mother poses a question to herself, asking if she wants to see life with her baby even at the cost of struggling with postpartum depression and thoughts of suicide. After she answers yes, a montage of photos and videos of happy moments of the mother and baby together begins.
Can't remember early life	
Postpartum depression makes it hard to remember child's early life	The video shows a mother pretending to pull a knife out of her chest with text that she could not remember the newborn stage of her child's life because she was "so depressed." In the video description, the creator writes that she wishes she had taken more videos and pictures during that time.

Navigating Anxiety and Anger

Mothers with depression shared feelings of anxiety and anger when interacting with their children. Many mothers experienced perseverative intrusive thoughts of something terrible happening to their child. These thoughts frequently related to the child passing away while asleep, though scenarios varied from the child choking while eating to others making the child sick. One creator mouthed a sound bite to recreate a conversation with her obstetrician, who instructed her that pulling over her car every time her baby fell asleep to check if her baby was breathing was a sign of postpartum anxiety. Some mothers had ego-dystonic intrusive thoughts of harming their baby, but more often, anger toward the child was a genuine feeling. Triggers for anger included difficulties with child sleep, crying, screaming, and sensory overstimulation. Still, more broadly, many mothers noted that their thoughts and feelings arose without warning. Only a few mothers explicitly mentioned anxiety or anger as a manifestation of postpartum depression. For example, one mother said, "It can come in so many different forms: anger, rage, depression, sadness."

In reaction to anxiety and anger, mothers engaged in behaviors to protect their children. For example, mothers compulsively checked if their child was safe while sleeping or vigilantly watched them, often resulting in poor sleep; some used baby monitoring devices to try to alleviate their fears. Mothers sometimes displaced their anger by hitting objects or themselves. In addition, they physically separated themselves from their child if they had these thoughts of hurting them. Several mothers brought up reluctance to share these feelings with their doctors and family members for fear of negative judgment.

Creating Physical and Emotional Boundaries

Mothers exhibited avoidant behaviors or attitudes toward their children. Some mothers expressed the need for a break from caregiving for personal relief due to childcare-related stress. Sensory overload, including loud noises and frequent touch, was a common stressor. One mother described feeling physically in pain due to hearing their child's cries. Other mothers needed to physically relocate in order to calm their fluctuating emotions (sadness, anger, and frustration). For example, some women who felt frustrated would remove themselves from the vicinity of their child to avert lashing out at the child. In addition to personal relief, women expressed fear that their emotional state may negatively impact their child. For example, some creators disclosed that they would conceal their own distress by leaving the room when crying or putting on a happy façade in hopes of minimizing the impact their observable distress may have on their child. Other women described having frequent fantasies where they are forced out of a caregiving role (eg, sickness, suicidal thoughts, and running away).

Overwhelmed by Demands of Caregiving

Mothers struggling with postpartum depression were often overwhelmed by daily caregiving tasks, causing them to feel

XSL•FO
RenderX

depleted or on the verge of a breakdown. As the tasks piled up on each other, many shared a feeling of inadequacy, doubting their competence as mothers. These tasks include feeding, diapering, meal preparation, toileting, and managing sleep routines. Challenges with breastfeeding were pronounced, leaving mothers feeling incapable, which further worsened their mental health. Consequently, some moms switched to formula feeding, though they felt guilty about whether this was best for their child. Caregiving was often described as all-consuming, limiting mothers' time to care for themselves, as evidenced by several videos showing mothers alone in a secluded area (eg, bathroom) away from their children. Relatedly, many women noted a lack of caregiving support, and several videos featured women caring for multiple children. Depressive symptoms such as low energy made it hard to care for their child as desired. Some women were able to get support from family at times when depression left them unable to take care of their children.

Subverted Expectations

The gap between the idealized image of motherhood and experiencing motherhood with postpartum depression left women with negative images of themselves as a mother. Due to depression, mothers expressed being unable to experience the joy and bond with their children that they anticipated. Consequently, mothers expressed feeling incompetent, with many creators asking, "Am I a good mother?" Mothers revealed feeling shame and guilt over their perceived nonconventional emotional state. One mother recounted expecting an instantaneous bond with her child and described feeling shame and guilt when she did not feel the connection early on. Depression also caused tiredness and sensitive emotional states, making it difficult for mothers to fulfill their own image of an ideal parent. Subverted expectations affected mothers both in the present and past. Some mothers expressed regret over missing out on the regular interactions they believed a parent and child should experience in early life due to depression or related tiredness, feeling overwhelmed, or delayed bonding.

Enduring and Finding Strength Through the Challenge of Postpartum Depression

Mothers with postpartum depression shared how they found the strength to persevere through their relationship with their children. Despite struggling to have the energy to get up each day and fulfill the demanding tasks of motherhood due to their depression, these mothers identified that their children were their primary motivating factor to carry on. Often, mothers stated that the smiles on their children's faces were uplifting. Music used in these videos often had resilience-themed lyrics such as "Rise up," "You are my sunshine," and "Don't give up." Some mothers shared a neutral sentiment, feeling that they must take care of their child—and would not let depression hinder their caregiving. Additionally, some mothers expressed their children sparked their desire to seek treatment.

Can't Remember Early Life

Some mothers noticed they had little memory of their child's early life months. These missing memories include important milestone moments, as well as day-to-day caregiving. With this realization came deep sadness that postpartum depression had robbed these special moments from them. This realization often came when their child was older or as their depression began to improve. Frequently, mothers were only reminded of these memories when presented with a picture of their child. Some women used photo montages in their videos to symbolize missed memories.

User Engagement

User engagement statistics for these categories across all videos are provided in Table 2. Overall, videos featuring content on navigating anxiety and anger, as well as subverted expectations, received the most views, likes, and comments. Users most frequently shared videos on subverted expectations and creating physical and emotional boundaries. Sensitivity analyses using normalized (log-scaled) follower counts found similar trends (Table S2 in Multimedia Appendix 1).

Table . User engagement of videos by content category.

Category	Videos, n (%)[a]	Views, median (IQR)	Likes, median (IQR)	Shares, median (IQR)	Comments, median (IQR)
Overwhelmed by demands of caregiving	64 (40)	39,700 (10,586 - 142,300)	3966 (1047 - 14,900)	52 (7 - 282)	128 (42 - 550)
Subverted expectations	56 (35)	50,050 (17,575 - 171,275)	4419 (1191 - 17,225)	80 (6 - 292)	147 (31 - 375)
Navigating anxiety and anger	53 (33)	67,600 (18,800-155,800)	6123 (1654 - 13,600)	49 (5 - 290)	132 (40 - 532)
Enduring and finding strength through the challenge of postpartum depression	26 (16)	27,600 (11,025-86,925)	1856 (553 - 10,734)	10 (1 - 110)	40 (16 - 285)
Creating physical and emotional boundaries	25 (16)	42,200 (10,800-91,800)	2774 (867 - 9932)	69 (4 - 223)	77 (25 - 315)
Can't remember early life	10 (6)	32,450 (25,125-211,075)	4180 (1970 - 6808)	24 (10 - 89)	36 (17 - 97)

[a]Data are expressed as n (%) of 159 videos because a single video can have multiple categories.

XSL•FO
RenderX

In regression analyses, videos on navigating anxiety and anger and subverted expectations increased the views, likes, shares, and comments by 61% to nearly 400% (Table 3). Content featuring the overwhelmed by demands of caregiving category also increased likes, shares, and comments, but not views. Content on resilience in the face of postpartum depression was more highly liked (rate ratio 1.60, 95%CI 1.00 - 2.57) but less likely to receive comments (rate ratio 0.48, 95%CI 0.30 - 0.78). Across all metrics, users engaged less with videos on creating physical and emotional boundaries. We found a small negative association between the log number of followers and all engagement types. Sensitivity analysis of creators with less than the median number of followers mostly corroborated these main findings with the following exceptions: the associations of enduring and finding strength through the challenge of postpartum depression, overwhelmed by demands of caregiving categories, and number of followers with engagement were consistently negative, nonsignificant, and positive, respectively (Table S3 in Multimedia Appendix 1).

Discussion

Principal Findings

This qualitative content analysis is the first study to examine the MIB in the context of postpartum depression using short-form videos. Nearly 150 mothers shared their experiences bonding with their children, resulting in 6 categories that advance understanding of this topic. Analysis of engagement metrics across categories added information on topics that resonated most with users. These findings support the use of short-form videos to enhance our understanding of lived experiences.

Video Content

Many of these categories reflect themes in the literature. The subverted expectations category aligns with prior studies discussing the clash between mothers' personal or societal expectations and the lived reality of postpartum depression [31,32]. Regarding bonding specifically, we found women worried that they were not the "good mother" they expected and felt associated guilt and shame. Unrealistic expectations of having an instantaneous emotional connection with their child contributed frequently to their mothering assessment. Regret was another prominent feeling, with mothers reporting remorse for missing out on moments with their children. As in Beck's [12] paper, depression was frequently described as "robbing" moms of precious time with their young children.

Several studies report that mothers with depression feel overwhelmed by caregiving responsibilities. Our results similarly find that the symptoms of depression, such as lack of energy, low mood, and lack of joy, compound the everyday challenges of raising a young child [12,33]. We found that poor maternal sleep and breastfeeding often contributed to mothers feeling like they could not meet these demands. Mothers could not refuel because they often could not take a break, or as one mother described, get "me" time.

Although anxiety and anger have long been recognized as manifestations of postpartum depression [34,35], few women in this study directly associated their anxiety or anger with their depression. Previous qualitative and quantitative studies of postpartum depression [35,36] describe symptoms such as intense intrusive thoughts and outbursts of anger, both provoked and unprovoked, which align with the experiences categorized as navigating anxiety and anger in this study. The low attribution of these symptoms to depression in this study might result from greater awareness and screening for postpartum depression compared to anxiety or anger. Therefore, even if anxiety or anger are sequelae or independent conditions, mothers might not have perceived them as symptoms of depression.

Despite this, mothers commonly described anxiety and anger as negatively affecting their bond with their children. Experiences of obsessions and compulsions, as highlighted in other qualitative studies [12] and our research, demonstrate the significant role that postpartum-specific anxieties have on the MIB. Indeed, postpartum anxiety impairs bonding, leading to pathological anger and infant-focused anxiety [37]. Prior research [12,36] has also shown that depressed mothers experience anger but find ways to avoid taking it out on their children, akin to how mothers on TikTok coped.

The creating physical and emotional boundaries category, characterized by behaviors or wishes to be separated from the infant, shared some similarities with a study of posts on a postpartum depression internet forum [17]. That study found that desires to be separated from the child manifested with thoughts or feelings of hurting the child. However, mothers in this study were more avoidant rather than aggressive. In addition, though some mothers noted thoughts of suicide, descriptions were less explicitly expressed in videos than in internet forum posts. These differences may be due to reluctance to share these thoughts by video, which is less identity-preserving.

In contrast, the enduring and finding strength through the challenge of postpartum depression and can't remember early life categories are less represented in the literature. Prior studies similarly found that mothers with postpartum depression expressed positive feelings toward their child or felt an obligation to meet their child's needs despite postpartum depression. Our results go a step further: for some mothers, their bond with their child offered comfort and reassurance. We know of a similar finding in one study of West African mothers residing in the United Kingdom who described their baby as a source of pride or distraction from distress [38]. Some mothers had difficulty remembering their child's early life because they were trying to "survive." Without these memories that connect and strengthen the bond between mother and child, these mothers felt deep sadness and regret. Traumatic events, such as childbirth trauma, can cloud memory, but only 2 included videos in this category mentioned trauma. Given the lack of prior literature on this phenomenon, it should be further explored in future work.

Determining mothers' motivations for sharing these personal experiences on social media is challenging without direct inquiry. Studies have shown that self-expression is a primary motivation for people with mental health conditions to share content on social media [39-41]. Creators, particularly on platforms like TikTok, are often willing to share personal experiences because they perceive a safe environment free from negative judgment [39,40]. This perceived safety encourages those with stigmatized conditions or identities to share their experiences [39,42]. Other motivations, such as the desire to receive social support or gain social status, are possible and could influence the type of content shared. The congruence of our findings with previous research using interviews, including in women diagnosed with clinical depression [12], lends credibility to our approach of analyzing short-form videos. Future research should interview creators to better understand their motivations and how these motivations influence the content they produce.

The technological features of social media platforms likely influence how women express their lived experiences. Women used the various multimedia affordances provided by the video-sharing platform to share their experiences. In addition to text, they often added sound bites or music to convey meaning. Visual effects such as photo montages and

XSL•FO
RenderX

re-enactments of how postpartum depression affected bonding were another way mothers used the medium. Although most videos were less than 30 seconds, this multimodal content added to the richness of the content.

User Engagement

Videos featuring 3 categories well-represented in the literature—subverted expectations, navigating anxiety and anger, and overwhelmed by caregiving—received more views, likes, shares, and comments. According to the uses and gratifications theory [43], people engage with content that meets their desires and needs. Users "like" content to express appreciation for the material they find relevant, interesting, or emotionally engaging [39,44]. Users are more likely to engage with mental health content that shares personal experiences and experiential knowledge [45,46]. This trend is noticeable on TikTok, where users frequently share personal stories and information, often presented in creative or humorous ways. In addition, users are drawn to experiences that resonate with their own [39,47]. The challenges of motherhood, many of which are unexpected, are relatable experiences represented by these categories. However, in postpartum depression, these challenging experiences pervade the mother's thoughts and actions, impairing the bond with their child.

Decreased likes, shares, and comments for the creating physical and emotional boundaries category indicate that users were less inclined to engage with videos about taking a break or fantasizing about separation from their child, possibly due to the stigma associated with appearing to want to abandon their responsibilities as a mother. However, content featuring anger generated more engagement, suggesting that anger without the expectation of abandoning the mother role may be the key difference. Content on resilience was well-received, nearing significance for increased likes. However, these videos are less likely to be commented on. This may reflect that users wanted to show support but may not have personally felt resilient or that it was actionable (eg, sharing advice). A study of depression on the Chinese version of TikTok found parallel results where positive portrayals of general depression had less engagement, which was attributed to positive content garnering less sympathy [48].

Our findings are further strengthened by the observation that videos from creators with small or modest followings were well-represented and received significant engagement. This suggests that diverse perspectives on postpartum depression, not just those from influencers with large followings, are valued. This could be attributed to TikTok's algorithm, which promotes videos that people consistently watch and interact with to a broader audience, resulting in increased engagement. The potential of content creators with small followings to create a viral video is one of the draws for people to create content on TikTok [49].

Clinical Implications

Our findings provide practical ways for clinicians to support bonding in depressed mothers. Across all these categories, mothers with postpartum depression tried various ways to cope with the challenges of bonding with their children. However, internalization of their bonding difficulties caused self-blame with associated shame and guilt, as well as isolation. Normalizing mothers' experiences, given their commonality and the resulting shame, is therapeutic. For instance, clinicians can reassure mothers that it often takes time to develop an emotional bond with their child. Based on the high engagement, these videos may already be beneficial by normalizing these experiences. Self-compassion approaches that reduce shame and guilt effectively enhance bonding and reduce depression [50,51]. Sharing ways to improve sleep for moms and infants and strengthen social support would be helpful for overwhelmed mothers, especially those with multiple young children. Health care professionals can change the narrative by emphasizing that not every mother can breastfeed.

Further, our findings indicate that assessment of bonding in the context of postpartum depression should consider anxiety, anger, and parenting stress. Asking only about depressive symptoms will likely miss many women with bonding difficulties. Although clinicians may be reluctant to ask about anger toward the child or the mother's escape fantasies, our results suggest that they should. It is important to acknowledge that mothers' reluctance to share their struggles because of fears about child protective services removing their children is not without basis. Informing mothers on the difference between what is considered maltreatment and what is not may provide reassurance. We believe giving mothers information and allowing them to share as they so choose is a beneficial intervention within itself and opens the door to future conversations.

Limitations

Although our findings are well supported by prior work, only publicly available videos with many views were reviewed. This enabled us to examine videos that resonate with many users, but further work is needed to determine if these categories are truly representative of bonding for women struggling with depression. In addition, while many social media researchers use hashtags to identify and learn about specific phenomena [22], it is unknown whether mothers in the videos have depressive symptoms or clinical depression. Nonetheless, subclinical depressive symptoms alone can negatively affect bonding [52]. In addition, demographic information such as maternal age, race, or sex could not be determined. We did not see videos featuring men with postpartum depression in our video corpus, highlighting an area for future investigation. The vast majority of women were from the United States followed by other Western countries. This is likely because we required videos to be in English. The concurrent findings in mothers from non-English speaking cultures are reassuring, but our approach limits generalizability.

Another limitation is the relatively low but acceptable IRR for the codes. The low IRR reflects the challenges of applying 21 nonmutually exclusive potential codes to short-form videos. Moreover, these codes were applied to 30 overlapping videos used for calculating IRR between each pair of coders, resulting in some of the codes being rarely applied. Consequently, even a single discrepancy between 2 coders when applying a code could lead to a moderate Krippendorff α reliability score. Two of the 3 codes with the lowest IRR of 0 ("Mother perceives their

XSL•FO
RenderX

child has negative feelings about them" and "Mothers put up physical or emotional boundaries for relief") were derived from the prior literature review. This suggests that these 2 codes may have been less relevant to the current dataset. As a result, one of these codes was excluded when codes were abstracted into categories ("Mother perceives their child has negative feelings about them"). While coders conducted several rounds of review to determine if initial deductive codes were present, further rounds may have helped validate these codes and improve IRR."

Conclusions

Overall, our research demonstrates that short-form videos provide a meaningful lens through which to explore mothers' experiences with postpartum depression, particularly its impact on the MIB. Knowledge gleaned helps us understand mothers' specific challenges and thereby develop ways to support them.

Acknowledgments

This work is supported by the UCLA Depression Grand Challenges Judith Young Fellowship awarded to KS. The funder had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

Data Availability

Datasets generated or analyzed during this study cannot be made publicly available due to potentially identifying information (eg, biometric) that may compromise privacy.

Authors' Contributions

KS conceived and designed the study. All authors reviewed and coded videos. All authors contributed to the interpretation of data. KS conducted the statistical analysis. All authors contributed to manuscript drafting and editing.

Conflicts of Interest

None declared.

Abstract

Background: Global medical tourism for aesthetic surgery has become a popular phenomenon through ease of access in the digital era, though such services are not without potential risks. The application of infodemiology for global health surveillance may provide unique insights into unknown patient travel patterns and surgeon workforce dynamics abroad.

Objective: This study aimed to evaluate American cosmetic tourism trends in oculofacial plastic surgery, including demand profile and qualifications of the most sought-after international eyelid surgeons on social media.

Methods: This cross-sectional infodemiology study queried Google Trends to assess US interests in aesthetic eyelid surgery abroad in 25 destination countries from 2013 to 2023. The highest-rated content posted by 55 eyelid surgeons (US: n=11; international: n=44) on a social media platform (Instagram; Meta Platforms) was evaluated. The main outcomes included Google search volumes for aesthetic eyelid surgery for each destination country, as well as specialty training and professional medical society affiliations of popular eyelid surgeons on social media in each of these countries.

Results: The top 5 destinations Americans sought for aesthetic eyelid surgery abroad were South Korea, Mexico, Canada, Turkey, and China. Interest in eyelid surgery abroad remained stable over the last decade despite 118% growth in blepharoplasty searches. Social media indicated eyelid surgeons abroad were more often general plastic surgeons than in the United States (30/44, 68% vs 2/11, 18%; *P*=.003). US surgeons more frequently completed oculofacial plastics, facial plastics, or aesthetic plastics fellowships compared with international surgeons (9/11, 82% vs 10/44, 23%; *P*<.001) and had membership in professional medical societies (11/11, 100% vs 22/44, 50%; *P*=.002).

Conclusions: American demand for international eyelid surgery remained stable over the past decade despite a 2-fold increase in the US interest for blepharoplasty. Digital epidemiology data reveal a shortage of international surgeons with specialized aesthetic eyelid fellowship training or professional society affiliations on social media among the preferred destinations for Americans seeking aesthetic eyelid surgery. These findings may provide beneficial insights for patients interested in traveling abroad for eyelid surgery, as well as for surgeons or academic societies seeking to increase social media presence or patient-directed educational content via social media engagement.

(JMIR Infodemiology 2025;5:e64639) doi:10.2196/64639

KEYWORDS

cosmetic tourism; oculofacial plastic surgery; aesthetic eyelid surgery; Google Trends; social media; travel medicine; global health; infodemiology; digital epidemiology; Instagram; eyelids; aesthetic; medical tourism; eyelid surgery; plastic surgery; blepharoplasty

Introduction

The digital transformation driven by the internet and social media has reduced international boundaries in medical care, enabling aesthetic surgeons worldwide to market their services to patients abroad for cosmetic tourism [1].

Travel abroad for discounted cosmetic surgery may offer some putative benefits, including anonymity, access to procedures unavailable locally, and all-inclusive medical tourism packages. However, such services are not without potential risks or untoward consequences. Considerations include variable preoperative counseling, inadequate follow-up, inconsistent quality of care, language barrier, postoperative care burden on

XSL•FO
RenderX

the home health care system, and financial and legal challenges in the event of complications [2,3]. Furthermore, centers abroad may not hold surgeons to the same training standards or safety regulations as the United States [4].

Eyelid surgery ranks third in aesthetic surgeries worldwide [5]. Google Trends (Alphabet Inc) is a valuable tool for health information–seeking behavior and has been employed to analyze aesthetic surgery demand within oculofacial plastic surgery (OPS), facial cosmetic surgery, facial feminization surgery, and cosmetic tourism for plastic surgery [3,6-8].

Social media is a dominant platform for medical advice, patient education, and business marketing in this field [9]. A study of nearly 400 survey participants showed that 49% (n=193) of patients found their oculofacial plastic surgeon on social media, with more than two-thirds choosing Instagram (Meta Platforms) as the preferred social media platform to find an oculofacial plastic surgeon [10].

Previous studies on social listening within OPS have largely focused on marketing strategies through content category analysis [11]. In this regard, Cheng et al [9] showed that the OPS content category amassing the most views was "live procedure or surgeries" followed by "educational" and "patient experience." Park et al [12] demonstrated that OPS photographs were more successful than videos, carousel presentation was better than collage, and featuring the posting doctor, especially when smiling and wearing a white coat, increased public engagement. Similarly, other social media listing research in aesthetic plastic surgery and ophthalmology have demonstrated the success of various hashtag utilization in social media marketing and the prevalence of inaccurate medical information among patient-generated Reddit discussions [13,14].

This study fills an important gap in the social listening literature for eyelid surgery from the perspective of global health and, to the authors' knowledge, is the first paper examining social media as a space for cosmetic tourism patients to find international OPS providers. The authors aimed to use a digital epidemiology approach to analyze current global health trends in OPS cosmetic tourism sought by Americans over the last decade. Furthermore, this study undertakes an analysis of social media data to compare training backgrounds and professional academic society affiliations of social media's most popular international eyelid surgeons. These findings may provide beneficial insights for patients interested in traveling abroad for eyelid surgery, as well as for surgeons or academic societies seeking to increase social media presence or patient-directed educational content via social media engagement.

Methods

Ethical Considerations

This cross-sectional digital epidemiology study followed the World Medical Association's ethical principles for medical research involving human participants outlined in the Declaration of Helsinki as amended in 2013. Institutional Review Board approval was not required as publicly available data were used. No identifiable patient information was involved in this study, and no compensation to participants took place. These methods were adapted from previous publications [6,13,15,16].

Google Trends

In order to ensure that search terms accurately represent the intent of Americans searching the topic of aesthetic eyelid surgery abroad in an international destination, the Google Trends query was designed in the following way. Google Trends relative search volume (RSV) for US interest in aesthetic eyelid surgery abroad from April 1, 2013, to March 31, 2023, was collected on April 1, 2024. The query output is search volume as arbitrary values ranging from 0 to 100 for each query (maximum 5 search terms at a time) and referenced to the highest peak search popularity (set at 100) for the given terms, region, and time. As such, a standard RSV reference range was implemented across all 25 search terms by using a bracket type elimination where all queries were tested until the maximum was identified (Korea), and therefore Korea was always included as the most popular peak term (100) within each set of 5-term queries to ensure that all RSV values were relative to the same reference point. The location of origin of the Google searches was limited to the US geographic filter, and the "Cosmetic Surgery" category filter was applied to limit the output to aesthetic-surgery–related searches. A variety of search term combinations were generated and tested through trial and error until the term combinations with the greatest output were identified in order to minimize cells with low data counts. As a result, "eyelid nation" was found to produce the most data for temporal country analysis, while "blepharoplasty" produced the most data for geographic analysis in the United States. Quotation marks were not included in any queries.

A total of 25 destination countries were included according to the International Society of Aesthetic Plastic Surgery (ISAPS) Global Survey 2021 most popular cosmetic surgery destinations [5]. As such, the following twenty-five search terms were applied: (1) eyelid Argentina, (2) eyelid Australia, (3) eyelid Brazil, (4) eyelid Canada, (5) eyelid China, (6) eyelid Colombia, (7) eyelid France, (8) eyelid Germany, (9) eyelid Greece, (10) eyelid India, (11) eyelid Italy, (12) eyelid Japan, (13) eyelid Korea, (14) eyelid Mexico, (15) eyelid Netherlands, (16) eyelid Portugal, (17) eyelid Romania, (18) eyelid Russia, (19) eyelid Saudi Arabia, (20) eyelid Spain, (21) eyelid Taiwan, (22) eyelid Thailand, (23) eyelid Turkey, (24) eyelid United Kingdom, and (25) eyelid Venezuela. Control terms as a proxy for levels of general internet traffic in the same time period included "weather," "sports," "google," and "news." RSV data for aesthetic eyelid surgery overall in each US state during this period were extracted using the search topic "blepharoplasty."

To evaluate the most popular destination countries based on average search interest, the average search volume from 2013 - 2023 for each country were compared. To analyze the changes in search interest over time, the following calculations were performed to normalize aggregate RSV data on a standard scale of 0 to 100. First, the search volume of all international countries was summed together for each month from April 2013 to March 2023 to be termed eyelid surgery abroad. The same was done for the control terms. The monthly aggregate data for each category were then normalized to be set on a scale of 0 to

XSL•FO
RenderX

100 in the same fashion performed by Google Trends, which sets the maximum value of each category to 100. Normalization is achieved by dividing each monthly data point by the maximum value of the category, and then multiplying by 100. Next, the normalized monthly data for eyelid surgery abroad, blepharoplasty overall, and control were averaged into seasonal data based on the following seasons: Winter (December, January, and February), Spring (March, April, and May), Summer (June, July, and August), and Fall (September, October, and November).

Social Media

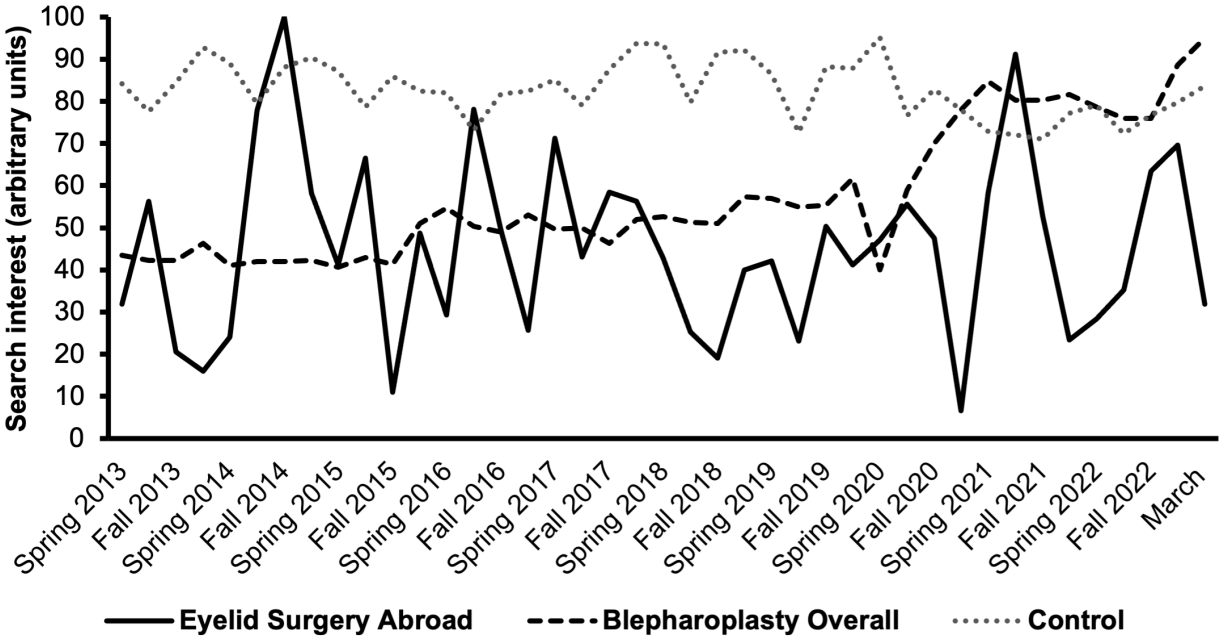
After identifying America's most desired eyelid cosmetic tourism destinations as above, the most popular international aesthetic eyelid surgeons on social media within those countries were identified in the following manner. The social media platform, Instagram, was chosen as it has been previously demonstrated that a majority of patients prefer Instagram for finding an oculofacial plastic surgeon [10].

Instagram was manually queried on May 1, 2024, for top eyelid surgery–related posts using the following search strategy based on previous methodologies [13]. Both hashtags and topic searches, including a variety of medical and layperson terminology, were used for the United States and each of the top 5 countries of highest demand extracted from the Google Trends analysis above (South Korea, Mexico, Canada, Turkey, and China). Through trial and error testing, additional similar hashtags or topic searches were added as needed to generate a minimum of 10 top posts for each country of interest. Instagram uses algorithm-based sorting to show a grid of the 9 top posts for a query based on factors like engagement (likes, comments, and shares), relevance to the query terms, and recency [13,17]. Search terms included the following: (1) #blepharoplastykorea, (2) #eyelidsurgerykorea, (3) #koreaeyelidsurgery, (4) eyelid surgery Korea, (5) #blepharoplastymexico, (6) #eyelidsurgerymexico, (7) #blepharoplastytijuana, (8) #eyelidsurgerytijuana, (9) eyelid surgery Mexico, (10) #eyelidsurgerycanada, (11) eyelid surgery Canada, (12) #blepharoplastyturkey, (13) #eyelidsurgeryturkey, (14) #eyelidsurgeryistanbul, (15) #blepharoplastychina, (16) #eyelidsurgerychina, (17) eyelid surgery China, (18) #blepharoplasty (representing United States), (19) #eyelidsurgery (representing United States), and (20) #eyelidlift (representing United States).

Content analysis was performed via a human annotator evaluating each top post for topic outputs to ensure they aligned with the theme identified for that topic. Inclusion criteria for content included posts relevant to eyelid surgery posted by an eyelid surgeon (ie, promoting services or medical tourism, photographs or videos in the operating room, before and after photos, anatomical diagrams, and patient-directed educational material). Duplicate posts, posts not relevant to eyelid surgery, or posts with an inability to access the appropriate information (blocked access or insufficient surgeon details) were excluded from the analysis. After removing duplicates, 55 unique posts were analyzed. The Instagram profile for each post was then mined for the surgeon's website, or if not listed then the surgeon's practice website was identified using search engine informatics querying the surgeon's name on Google. Data extracted from each surgeon's professional website included procedures, residency, fellowship, country of practice, professional medical society affiliations, warranties, and medical tourism packages. Data collected for membership to professional organizations were verified on the corresponding academic society website member lists and included American Society of Ophthalmic Plastic & Reconstructive Surgery (ASOPRS); Canadian Society of Oculoplastic Surgeons (CSOPS); American Academy of Facial Plastic & Reconstructive Surgery (AAFPRS); Fellow of the American College of Surgeons; American Society of Plastic Surgeons; European Board of Plastic Reconstructive & Aesthetic Surgery; Fellow of the Royal College of Surgeons of Canada; ISAPS; Oriental Society of Aesthetic Plastic Surgery; International Confederation for Plastic, Reconstructive & Aesthetic Surgery; Korean Academy of Facial Plastic and Reconstructive Surgery; Korean Society of Plastic and Reconstructive Surgeons; Asociación Mexicana de Cirugía Plástica Estética y Reconstructiva; and Canadian Society of Plastic Surgeons.

Statistical Analysis

Statistical analysis used Microsoft Excel Version 16.66.1 (Microsoft Corporation) and GraphPad Prism QuickCalcs (GraphPad Software). Descriptive statistics were used to analyze the search interest volume over time, as well as the demographics of the international eyelid surgeons. Chi-square tests compared proportions for categorical variables between international and US eyelid surgeons.



Results

Google Trends

Between 2013 and 2023, the top 5 destinations for Americans seeking eyelid surgery abroad were South Korea, Mexico, Canada, Turkey, and China (Multimedia Appendix 1). Despite 118% growth in blepharoplasty searches, interest in eyelid surgery abroad remained steady (Figure 1). The notable growth occurred recently, averaging 30.61 (SD 2.49) increased RSV from June 2020 to March 2023 compared with previous years from April 2013 to May 2020 (95% CI 25.73-35.49 RSV; $P<.001$). US states with the highest blepharoplasty RSV were Florida, California, Hawaii, Nevada, and New York. While complete state-level data for interest in eyelid surgery in all the destination countries were unavailable, California led the United States in searches for eyelid surgery in South Korea.

XSL•FO
RenderX

Figure 1. Google Trends search interest in cosmetic tourism for eyelid surgery**.** Despite periodic fluctuations, American Google Trends search interest in cosmetic tourism for eyelid surgery remained stagnant (0% growth) from 2013 to 2023, while overall interest in blepharoplasty rose 118.4%.

Social Media

In total, 55 top Instagram posts were included from aesthetic eyelid surgeons across ophthalmology, Otolaryngology-Head and Neck Surgery (OHNS), and plastic surgery. Within each discipline, qualifying fellowship training specializing in aesthetic eyelid surgery was examined. For ophthalmology, this included ASOPRS fellowship, CSOPS fellowship, or an unspecified OPS fellowship; for OHNS, AAFPRS facial plastic and reconstructive surgery fellowship or other unspecified or international facial plastic and reconstructive surgery fellowships; for plastic surgery, aesthetic plastic surgery fellowship.

When combining both the United States and international eyelid surgeons within each discipline, ophthalmology (7/10, 70%) and OHNS (9/13, 69%) were far more likely to have had fellowship training that included aesthetic eyelid surgery than plastic surgeons (1/32, 3%; $P<.001$) (Table 1). Of the plastic surgeons performing aesthetic eyelid surgery, 19% (4 abroad and 2 in the United States) were initially trained as general surgeons and subsequently obtained further training in general plastic surgery.

[i]Not applicable.

Looking specifically at the United States versus international surgeons, the US surgeons more frequently completed fellowships that encompassed aesthetic eyelid surgery–specific training compared with international surgeons (9/11, 82% vs 10/44, 23%; *P*<.001) (Table 1). Within ophthalmology, US aesthetic eyelid surgeons more often had OPS training compared with international surgeons (4/11, 36% vs 3/44, 7%; *P*=.009). Within OHNS, US surgeons more often had facial plastic surgery (FPS) fellowship training compared with international surgeons (5/11, 46% vs 4/44, 9%; *P*=.004), and especially had more AAFPRS fellowship training (5/11, 46% vs 1/44, 2%; *P*<.001). Interestingly, 100% (9/9) of the US ophthalmologists and US OHNS had done an OPS or FPS fellowship, respectively, compared with only 50% (3/6) of the international ophthalmologists and 50% (4/8) of the international OHNS, although this was not statistically significant (*P*=.06 and *P*=.09, respectively). General plastic surgery accounted for the majority of training for the most popular international eyelid surgeons, contrasting with a low proportion in the United States (30/44, 68% vs 2/11, 18%; *P*=.003). These plastic surgeons rarely had

XSL•FO
RenderX

aesthetic plastic surgery fellowship training both abroad and in the US (1/30, 2% vs 0/2, 0%; *P*=.61).

Aesthetic eyelid surgeons in the United States were more likely to have active membership in recognized professional medical societies than their international counterparts (11/11, 100% vs 22/44, 50%; *P*=.002). A summary of these professional societies is listed in Table 1.

Among aesthetic eyelid surgeons abroad, 27% (12/44) offered medical tourism travel packages, while only 5% (2/44) mentioned warranty systems for the financial handling of revisional surgery on their websites.

Discussion

Principal Findings

This infodemiology study indicates Americans primarily seek aesthetic eyelid surgery abroad in Asia and Europe (South Korea, Turkey, and China) as well as the US neighboring countries (Mexico and Canada). These findings align with existing plastic surgery literature. ISAPS 2021 ranked Turkey, Colombia, Mexico, Thailand, and Spain as top aesthetic surgery destinations [5]. Previous studies suggest these trends may reflect proximity (eg, Mexico and Canada in this United States–based study, or Spain in the largely European-based ISAPS study) and niche surgical offerings (eg, Thailand for gender reassignment or Colombia for breast, body, and extremity) [5,18]. South Korea's popularity for eyelid surgery among Americans may be linked to the nation's commonly sought-after idealized appearance referred to as the Korean look achieved through a distinct set of facial cosmetic procedures defined in South Korea and popularized by global exportation of South Korean popular culture [19]. These aesthetic surgeries produce a desired appearance for the East Asian face, focused on widening the eyes, narrowing the cheekbones and jawbones, and augmenting the nose tip. In this study, most interest in South Korean eyelid surgery originated from California, home to half a million of the United States' 1.7 million Korean Americans, suggesting a shared cultural desire for the Korean look [20].

This study demonstrates overall American interest in blepharoplasty doubled in the last decade with most growth occurring after the United States lifted COVID-19 restrictions in May 2020. However, this has not translated to a greater preference for international destinations for aesthetic eyelid surgery, possibly attributed to reopening patterns after COVID-19 travel restrictions. These findings expand on previous studies that found declines in domestic interest in oculofacial plastic, facial plastic, or general plastic surgery and a temporary rise in interest abroad during the pandemic [3,6]. By 2021, the United States rebounded to 85.7% of prepandemic cosmetic surgery volume, making the US surgeons more accessible than the surgeons abroad postrestrictions [5].

The US aesthetic eyelid surgeons popular on social media more often had fellowship training specializing in blepharoplasty techniques, including OPS fellowship or FPS fellowship. They were also more likely to hold membership in a professional medical society than their international counterparts. A recent study on problematic Instagram medical marketing demonstrated a significant number of physicians advertising as cosmetic surgeons without appropriate plastic surgery credentials [13]. Ideally, consumers should be aware of differences in specialty training and qualifications when selecting an aesthetic eyelid surgeon.

A quarter of international eyelid surgeons offered medical tourism vacation packages, involving substantial upfront financial commitments that may pressure patients to proceed with surgery. Cosmetic tourists may also encounter a lack of language concordance, psychological stress from traveling and recovering alone, inadequate follow-up, limited legal recourse, and surgical complications including perioperative fatalities [1-3]. Of note, few international aesthetic eyelid surgeons were observed to offer a warranty. It is customary in the United States for eyelid surgery practices to have a revisions policy addressing the possible event of additional corrective procedures; while this may not necessarily be displayed on the surgeon's website, it is an important aspect of the surgical discussion and consent process. For international surgeons, on the other hand, displaying the warranty policy on the surgeon's website may be more essential as reassurance to the patient. Of note, the Centers for Disease Control and Prevention recommends that cosmetic tourism patients should be informed of their rights and legal recourse before agreeing to travel outside the United States for medical care because of the high costs of complications and limited ability for legal action [21].

Aesthetic surgery remains a key contributor in the US $27.8 billion global medical tourism industry, earning high satisfaction ratings in some populations [22]. Future investigations should explore cost, desire for local expertise, and perceptions of international experience to better appreciate the American interest in aesthetic eyelid surgery abroad. In addition, an examination of a particular destination's aesthetic OPS niche may shed further light on cosmetic preferences and tourism patterns. Finally, an understanding of how social media's relative lack of international aesthetic eyelid surgeons with fellowship training that includes blepharoplasty techniques correlates to surgical outcomes and patient satisfaction would provide further insight for Americans seeking cosmetic tourism abroad. Such information may also help guide professional academic society resource allocation and social media engagement.

Limitations

Google Trends lacks patient demographics and outcomes, can be influenced by media exposure or user manipulation, and may encompass users beyond those seeking surgery. Social media may portend representation gaps for less tech-savvy surgeons. Instagram restrictions limit data from China, precluding conclusions about the country. Surgeons' websites may not disclose all details. While the Google and Instagram platforms are popular United States–based channels for health information–seeking, these may not represent the only relevant media platforms from an international standpoint. Relevant data for each country may not have been captured by the specific hashtags used; however, the presence of several duplicate posts among variations of hashtags and topic queries supports the appropriateness of these terms in highlighting the top content.

XSL•FO
RenderX

Analysis of surgical qualifications is limited as different countries have inherently different training and licensing regulations, as well as cultural variations and legal requirements in how they may be advertised. The study is limited to internet search trends and social media trends, but the reasons behind these trends remain unclear. The search terms designed for geographic identification may not represent all queries for eyelid surgery abroad. Rate limiting on posts collected on Instagram may confound the output for all or a number of countries. In consistency with previous research, the sample of social media data was queried at one point in time to control for temporal variations in content engagement; however, this strategy may limit the generalizability of the content to other seasons of the year. Given these limitations, the study should be received as exploratory, laying a preliminary foundation of novel insight in the unexplored area of cosmetic tourism for eyelid surgery.

Conclusions

This study used Google Trends and social media to identify preferred international destinations among US travelers seeking cosmetic eyelid surgery and examined specialty training of the most sought-after aesthetic surgeons in those countries trending on social media. It highlights the shortage of international surgeons with aesthetic eyelid surgery–specific fellowship training and membership in a recognized professional medical society. Further research is necessary to evaluate how these trends correlate with demographics, surgical outcomes, and niche surgical offerings.

Abstract

Background: As the global population ages, concerns about older drivers are intensifying. Although older drivers are not inherently more dangerous than other age groups, traditional surveys in Japan reveal persistent negative sentiments toward them. This discrepancy suggests the importance of analyzing discourse on social media, where public perceptions and societal attitudes toward older drivers are actively shaped.

Objective: This study aimed to quantify long-term public discourse on older drivers in Japan through Twitter (subsequently rebranded X), a leading social media platform. The specific objectives were to (1) examine the sentiments toward older drivers in tweets, (2) identify the textual contents and topics discussed in the tweets, and (3) analyze how sentiments correlate with various variables.

Methods: We collected Japanese tweets related to older drivers from 2010 to 2022. Each quarter, we (1) applied to the Japanese version of the Linguistic Inquiry and Word Count dictionary for sentiment analysis, (2) employed 2-layer nonnegative matrix factorization for dynamic topic modeling, and (3) applied correlation analyses to explore the relationships of sentiments with crash rates, data counts, and topics.

Results: We obtained 2,625,807 tweets from 1,052,976 unique users discussing older drivers. The number of tweets has steadily increased, with significant peaks in 2016, 2019, and 2021, coinciding with high-profile traffic crashes. Sentiment analysis revealed a predominance of negative emotions (n=383,520, 62.42%), anger (n=106,767, 17.38%), anxiety (n=114,234, 18.59%), and risk (n=357,311, 58.15%). Topic modeling identified 29 dynamic topics, including those related to driving licenses, crash events, self-driving technology, and traffic safety. The crash events topic, which increased by 0.28% per year, showed a strong correlation with negative emotion (r=0.76, P<.001) and risk (r=0.72, P<.001).

Conclusions: This 13-year study quantified public discourse on older drivers using Twitter data, revealing a paradoxical increase in negative sentiment and perceived risk, despite a decline in the actual crash rate among older drivers. These findings underscore the importance of reconsidering licensing policies, promoting self-driving systems, and fostering a more balanced understanding to mitigate undue prejudice and support continued safe mobility for older adults.

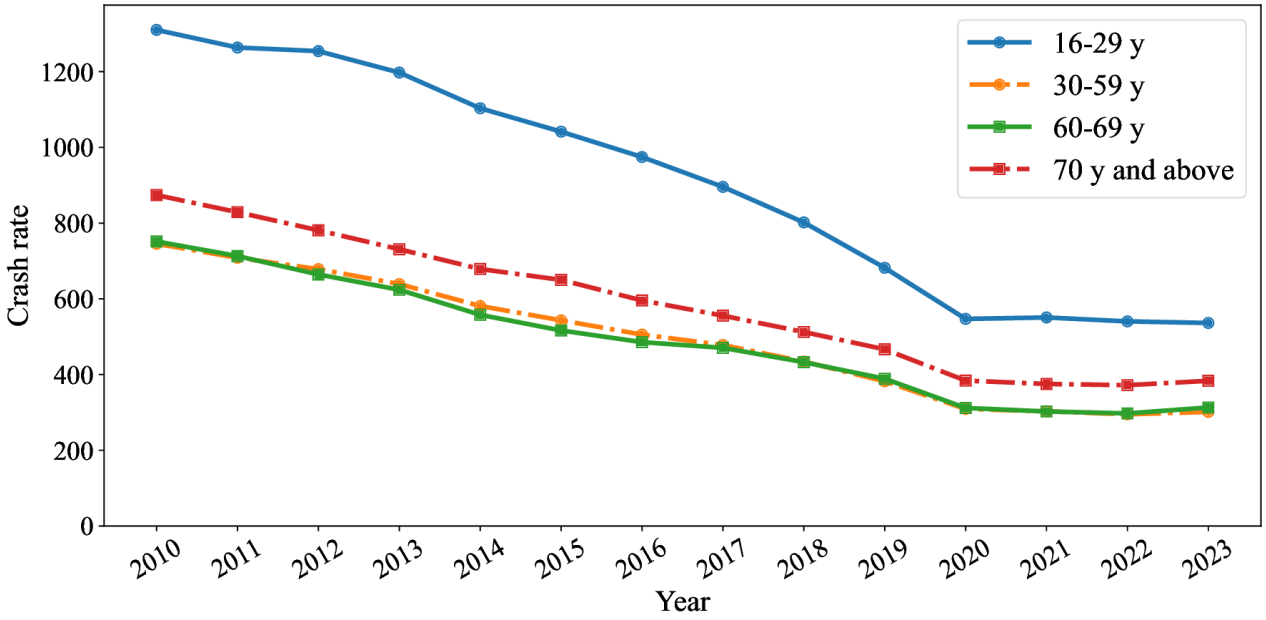
KEYWORDS

older driver; older people; ageism; social media; Twitter; sentiment analysis; topic modeling

Introduction

As the global population ages, concerns about older drivers are increasing. The share of the global population aged 70 years or older is projected to rise from 6.4% in 2023 to 11.7% in 2050 [1]. Japan is one of the most rapidly aging societies, with 23.6% of its population being 70 years or older in 2023. Concurrently, the proportion of driver's license holders among older Japanese people is also increasing, reaching 16.6% for those aged 70 years or older in 2023 [2]. In response to their decline in physical and cognitive functions, as well as tragic traffic crashes involving them, the National Police Agency of Japan has incrementally tightened licensing policies for them in 1998, 2002, 2009, 2017, and 2022 [3].



Research on older drivers' traffic safety frequently examines their risk of traffic crashes, neurological and physical impairments, and crash causes. A global meta-review [4] finds that older drivers have a higher risk of crashes and injuries even when controlling for travel time or distance, partly because they experience declines in vision, cognitive performance, reaction time, and physical ability, despite their strong adherence to traffic laws. This makes older drivers a higher-risk group in

XSL•FO
RenderX

traffic than younger drivers, who are more likely to be involved in crashes due to law violations or careless behavior. In addition to traffic crashes, studies have also discussed the effects of driving cessation, such as increased depressive symptoms [5,6] and reduced quality of life [7]. In Japan, research on older drivers is a relatively new field [8] and covers a range of topics, including dangerous driving associated with dementia [9], qualitative surveys of older drivers and their families [8,10,11], and discussions on licensing policies [12,13].

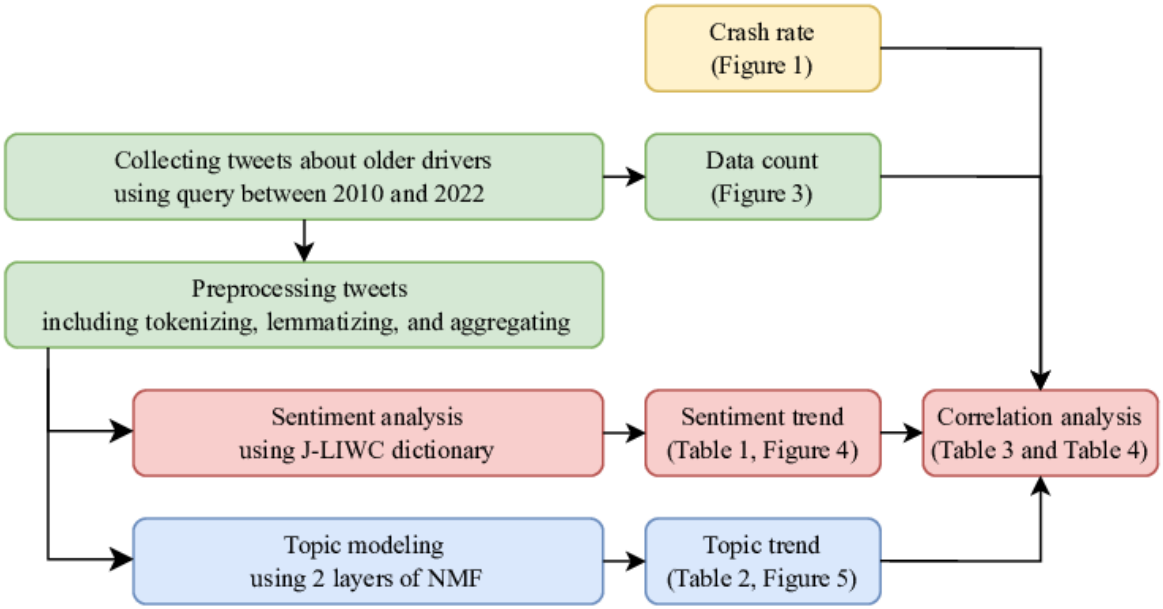
Although many studies highlight the risks associated with older drivers, they are not significantly more dangerous than other age groups in Japan when considering both their at-fault crash rate and the harm they cause to others. As shown in Figure 1, the at-fault crash rate (per 100,000 licensed drivers) for car and motorcycle drivers aged 70 years or older was 384 in 2023, which was higher than for those in middle age groups (30 - 59 y: 301 and 60 - 69 y: 313), but lower than for those in younger age groups (16 - 19 y: 1025 and 20 - 29 y: 497) [14]. Furthermore, the rate among those aged 70 years or older substantially decreased in the past decades from 874 in 2010 to 384 in 2023. It is also noted that their at-fault fatal crashes tend to result in fewer fatalities for occupants of other vehicles compared with fatal crashes caused by drivers in other age groups [15]. These statistics demonstrate that the risk of traffic crashes and resultant injuries imposed by older drivers is not as high as perceived, as driving failure frequencies do not significantly differ between age groups [4].

Figure 1. Traffic crash rates per 100,000 licensed drivers by year, categorized by age group (16 - 29 y, 30 - 59 y, 60 - 69 y, and 70 y and above).

Despite the decreasing crash rate, negative sentiments toward older drivers are still persistent in Japan. According to a survey by the National Police Agency, 85% (n=1698) of respondents (balanced by age and sex) perceive older drivers as dangerous, and 80% (n=1596) believe that licensing for older drivers should be revised [16]. Such sentiments are potentially influenced by media reports on older drivers and their crashes as well as stereotypes about older people. Recent studies suggested a negative tone toward older drivers in news reports [17], an increase in newspaper articles about them [18], and underreported of their crashes killing themselves [19]. However, discourse regarding older drivers in social media has not been explored despite the widespread use of various social media platforms.

Today, social media plays various roles in formal and informal communication at individual, organizational, and societal levels. The number of social media users escalates globally [20], with nearly 50% of Japan's population using Twitter (now X), a leading text-based social media platform [21]. Social media not only facilitates access to a broad range of information but also serves as a platform for public discussion, allowing individuals to express their views, opinions, and sentiments. As the reliance on online health information also intensifies [22], research into health-related topics on Twitter has expanded to include discussions on food security [23], type 1 diabetes [24], and various aspects of COVID-19, such as mask-wearing [25], vaccines [26-28], and the pandemic [29]. Consequently, applying text mining techniques, frequently employed to quantify the textual content and sentiment of tweets in these fields, offers valuable insights to facilitate a direct interpretation of societal discussions around health-related issues.

Given social media's impacts on public opinions and policy-making, gaining insights on older drivers and their crashes from social media—beyond conventional surveys [17,30]—is crucial for strategic planning of traffic safety. In this study, we aimed to (1) examine the sentiments toward older drivers in tweets, (2) identify the textual contents and topics discussed in the tweets, and (3) analyze how sentiments correlate with various variables. To achieve these goals, we conducted sentiment analysis, topic modeling, and correlation analysis, using over 2.6 million tweets on older drivers posted in the past 13 years.



XSL•FO
RenderX

Methods

Study Workflow

Figure 2 illustrates the workflow of this study, covering data collection and processing, sentiment analysis, topic modeling, and correlation analysis.

Figure 2. Diagram of the study workflow. Tweets are collected and preprocessed, followed by sentiment analysis, topic modeling, and correlation analysis. Each figure and table number corresponds to the main text. J-LIWC: Japanese version of the Linguistic Inquiry and Word Count Dictionary; NMF: nonnegative matrix factorization.

Data Collection and Processing

We collected tweets about older drivers posted between January 1, 2010 and December 31, 2022, using the Twitter application programming interface v2 [31] with Japanese keywords "(高齢 OR 老人) AND (運転 OR ドライバー)", or literally, "(old age OR older people) AND (driving OR driver)." To ensure the relevance of collected tweets, we examined the contents in a random sample of 1000 tweets and determined that 967 tweets pertained to older drivers or their transportation issues.

As part of text preprocessing, we removed symbols, emojis [32], URLs, and hashtags (#...), and normalized characters by converting them to lowercase and half-width forms. Tweets were then tokenized into words using MeCab [33] with the mecab-ipadic dictionary, with stopwords removed (Multimedia Appendix 1) and verbs and adjectives lemmatized. In addition, we consolidated tweets from the same user within the same quarter by merging their tokenized word lists into single documents. This approach reduces individual biases, enables dynamic trend analysis by quarter, and improves topic modeling accuracy by processing aggregated and extended textual content [34]. After pooling tweets by user and quarter, we removed words with an occurrence rate of less than 0.1% per quarter, resulting in 9287 unique words. Hereafter, we refer to the collection of quarterly tweets aggregated by each user as a "document."

Sentiment Analysis

To clarify the Twitter users' feelings toward older drivers, we first conducted sentiment analysis using the Japanese version of the Linguistic Inquiry and Word Count Dictionary (J-LIWC) [35]. Sentiment analysis quantifies the sentiment expressed in documents, using techniques ranging from word-based and context-based methods to deep-learning approaches. We adopted a word-based method for its interpretability and consistency with topic modeling, specifically using J-LIWC, which is psychologically validated and reliable in both English and Japanese.

The J-LIWC includes 69 categories in 4 broad categories—"psychological processes" (37 categories), "linguistic processes" (14 categories), "punctuation" (12 categories), and "other grammar" (6 categories). For this study, we used the "psychological processes" of the J-LIWC, aligning with our research objectives. The "psychological processes" consists of 10 subcategories, namely "affective processes," "negative emotions," "social processes," "cognitive processes," "perceptual processes," "biological processes," "drives," "relativity," "personal concerns," and "informal language," and under these subcategories, there are several further subcategories, as illustrated in Table 1. Throughout this paper, we refer to the further subcategories of the J-LIWC as sentiments.

XSL•FO
RenderX

Table . Proportion of documents containing words corresponding to 10 sentiments in the Japanese version of the Linguistic Inquiry and Word Count Dictionary's "affective processes," "negative emotions," and "drives" within 614,429 documents discussing older drivers posted from 2010 to 2022. In addition to proportions, results of linear regression (the formula $Yt=\beta0+\beta1Xt+t$) are represented by β0,β1, R^2, and *P* values.

Subcategory and sentiment		Tweets, n (%)	β0	β1	R^2	*P* value
Affective processes						
	Positive emotions	217,300 (35.37)	31.0	0.11	0.154	.004
	Negative emotions	383,520 (62.42)	46.1	0.36	0.462	<.001
Negative emotions

Topic Modeling

Next, we employed 2 layers of nonnegative matrix factorization (NMF) [36], a form of dynamic topic modeling. Topic modeling aims to extract latent textual data and generate topic distributions categorized as "static" (ignoring time) and "dynamic" (incorporating temporal variation) [37,38]. While many previous studies use latent Dirichlet allocation [39], it does not account for temporal trends, thus unsuitable for longitudinal studies. Several models have been developed to capture topic dynamics over time, such as dynamic topic model (DTM) [40], which is an extended version of latent Dirichlet allocation, 2 layers of NMF [35], and BERTopic [41]. DTM and 2 layers of NMF rely on a bag-of-words approach, whereas BERTopic uses word embeddings. This study opted for 2 layers of NMF as it provides a richer set of top words, higher coherence scores, faster performance than DTM, and, compared with BERTopic, offers objective evaluation metrics, enables topic distribution generation for each document, and eliminates the need for labor-intensive testing [36,42].

Two layers of NMF is a method for extracting dynamic topic distributions by applying a 2-stage NMF, an unsupervised dimensionality reduction technique that decomposes data into nonnegative factors. In the first stage, document-term matrix At for each time unit (quarter) *t* undergoes NMF, producing a "window topic," which represents topic distributions within each time unit. In the second stage, all "window topic"–term matrix B (a combination of all At) are further decomposed via NMF, resulting in a "dynamic topic," which incorporates temporal changes.

Following the previous study [36], we determined the optimal number of dynamic topics by testing a range between 25 and 90, selecting the one with the highest Topic Coherence using Word2Vec score [43]. TC-W2V score is defined as the mean pairwise cosine similarity between term vectors embedded using the word2vec model [44]. In this study, we employed the Japanese Social Media Corpus [45] as a large-scale word2vec model, trained on approximately 2 million Japanese words from social media and web sources (Multimedia Appendix 1).

Statistical Tests

In each section, we employ simple linear regression to analyze temporal trends in data counts, sentiments, and topics. The simple linear regression model is expressed as follows:

$$Yt= \beta0+\beta1Xt+ t$$

where Yt represents the dependent variable (eg, tweet count at quarter *t*) and Xt denotes the independent variable (eg, quarter *t*). The coefficient β1 indicates the rate of change, while the intercept β0 represents the baseline value when Xt is zero. The term t accounts for random fluctuations not explained by the model. For this analysis, we use the actual data count, the proportion of documents containing a given sentiment, and the mean topic proportion per time unit.

In addition, we examine the correlation between sentiments and traffic crash rates, data counts, and topics using Pearson correlation analysis. The correlation coefficient (*r*) is computed as follows:

$$r=\sum(Xt-X-)(Yt-Y-)\sum(Xt-X-)2\sum(Yt-Y-)2$$

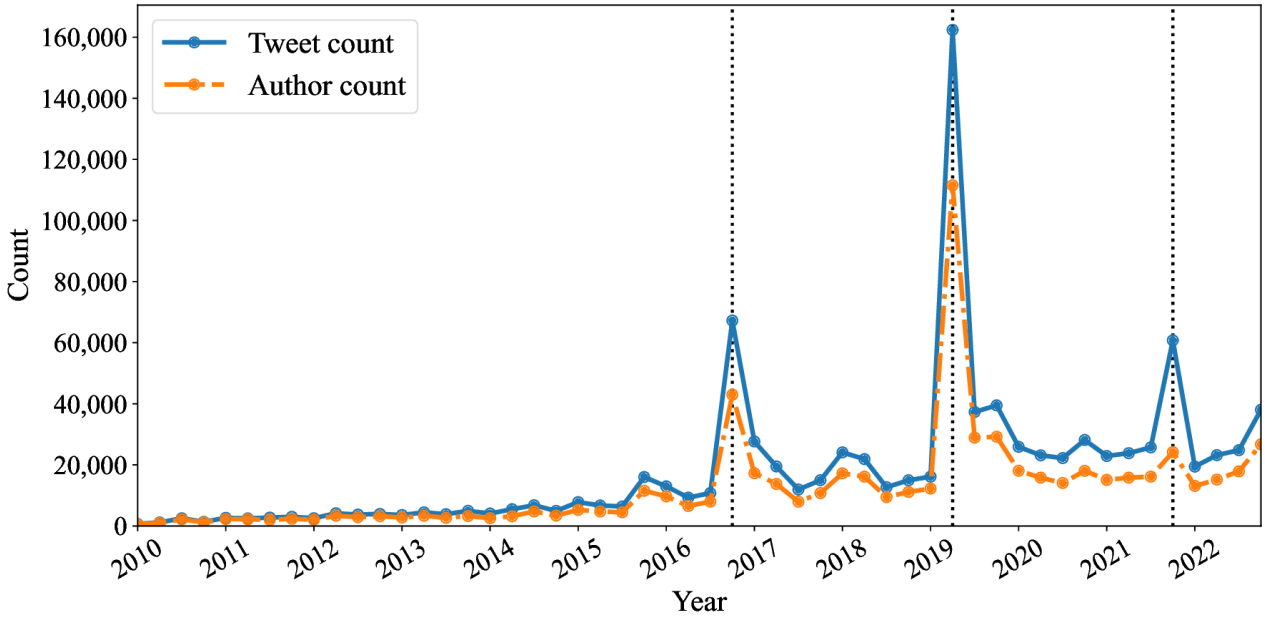
where Xt (eg, negative emotions at quarter *t*) and Yt (eg, tweet count at quarter *t*) represent the paired values of the independent and dependent variables, respectively, and X- and Y- denote their mean values. A positive *r* indicates a positive correlation, while a negative *r* suggests an inverse relationship.

To quantify the proportion of variance explained, we also compute the coefficient of determination (R^2) for regression models and the squared correlation coefficient (r^2) for correlation analysis. Significance levels are calculated under

XSL•FO
RenderX

the null hypotheses of β1=0 for linear regression and r=0 for correlation analysis.

Ethical Considerations



This study did not require institutional review board approval because it is an observational study that used only publicly accessible data and reported aggregate results with no personal identifiers. To maintain privacy and confidentiality, all personal identifiers were removed during data processing. Transparency was maintained throughout the study, with clear communication of its purpose, methods, and findings.

Results

Summary of Tweet Counts and Users

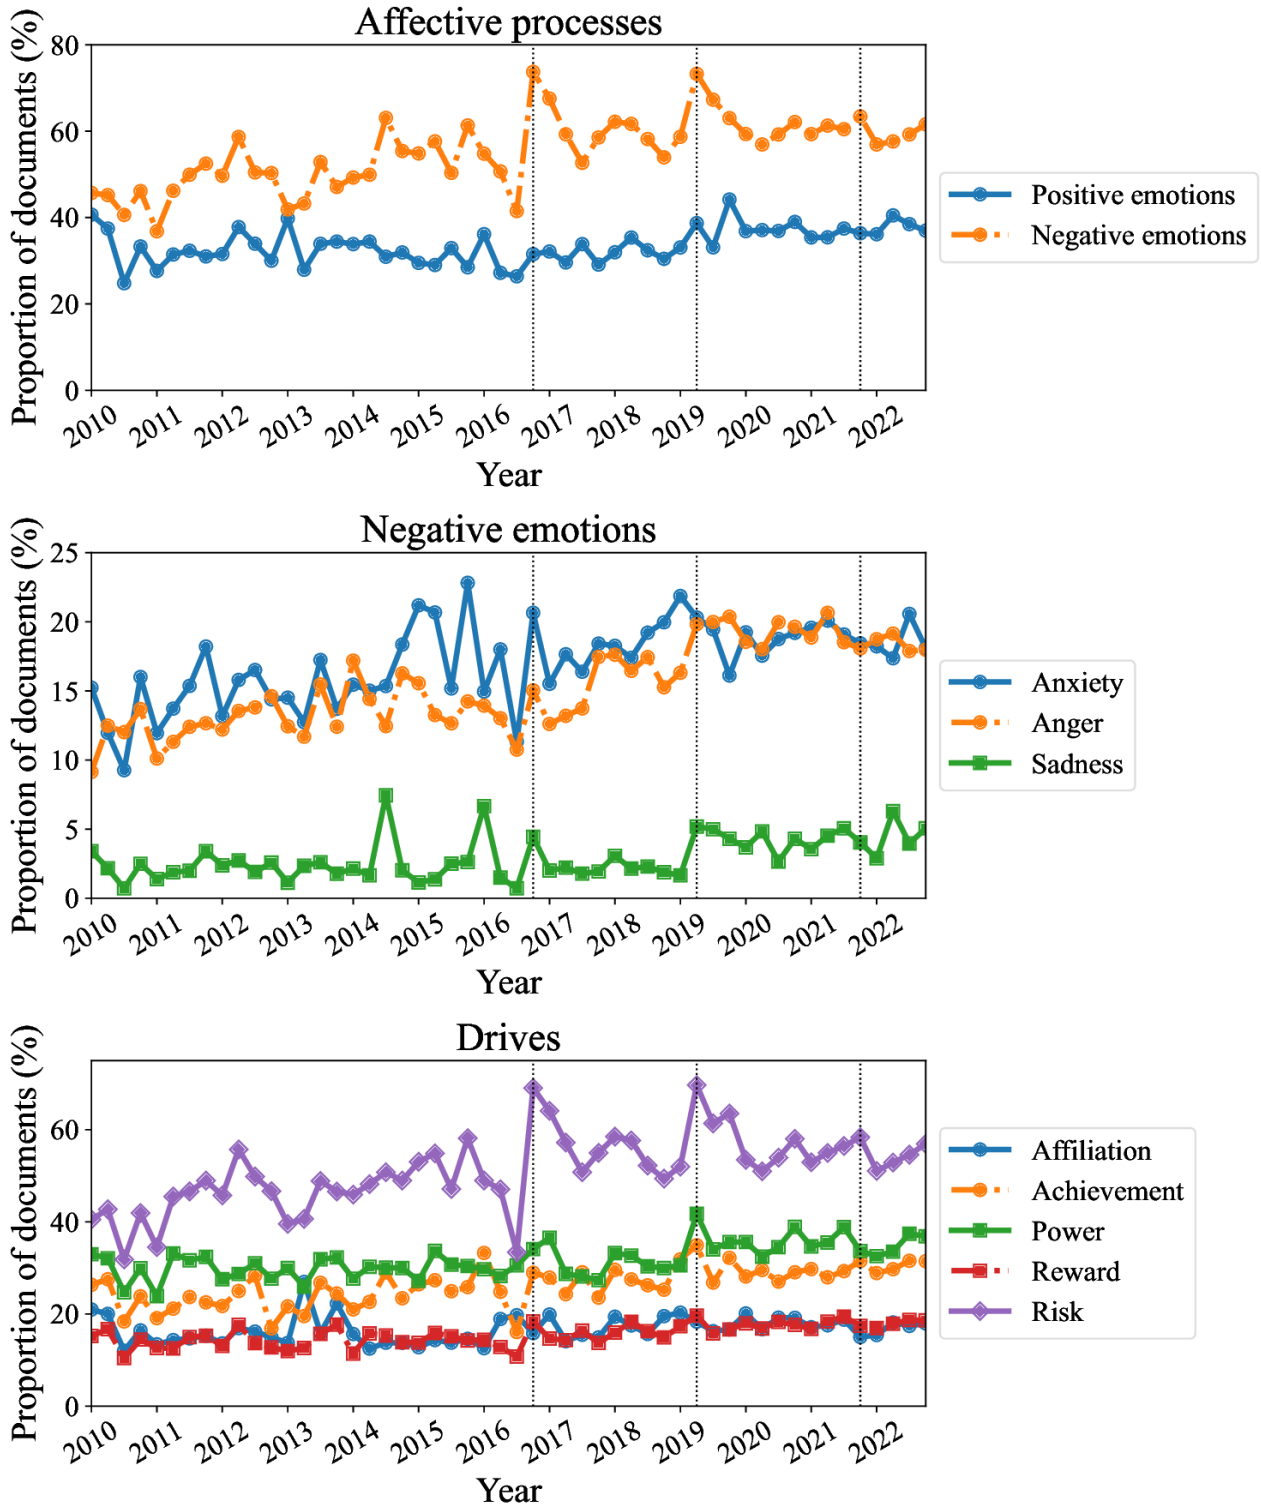
Our dataset contained 2,625,807 tweets from 1,052,976 unique users, comprising original tweets (n=767,419, 29.25%), retweets (n=1,678,133, 63.91%), replies (n=171,781, 6.54%), and quoted tweets (n=8474, 0.32%). To analyze primary opinions or original tweets, we excluded retweets and eliminated referenced text from quoted tweets and replies. Figure 3 illustrates the quarterly counts of original tweets and unique users discussing older drivers over a 13-year period. There has been a consistent presence of tweets and users, with a moderate increase over time. This trend is supported by linear regression (tweet count: β0=−3011.09, β1=832.75, R^2=0.256, P<.001; user count: β0=−1325.86, β1=534.90, R^2=0.238, P<.001).

Figure 3. Tweet and user counts related to older drivers by quarter from 2010 to 2022. Black vertical dotted lines indicate the 3 major tweet peaks.

Since 2016, the number of tweets per quarter has exceeded 10,000, rising to over 20,000 per quarter from 2019 onward. The highest peak occurred in the second quarter of 2019 (approximately 162,000 tweets), driven by a crash on April 19, 2019, in Higashi-Ikebukuro, Tokyo, where an 87-year-old man mistakenly stepped on the accelerator, killing a 3-year-old child and her mother and injuring 9 others [46]. The second peak, in the fourth quarter of 2016 (approximately 67,000 tweets), coincided with a series of crashes in Tochigi (November 10, 2016), Tokyo (November 12, 2016), and Miyazaki (November 13, 2016), where older drivers struck and killed pedestrians, sparking active public debate about older drivers [47]. Another significant peak in the fourth quarter of 2021 (approximately 60,000 tweets) followed a crash in Osaka, where an 89-year-old man mistakenly stepped on the accelerator, resulting in pedestrian casualties [48]. Hereinafter, we plot black dotted lines to indicate the 3 major tweet peaks in each figure.

Sentiments Toward Older Drivers

After processing, our final dataset comprised 614,429 documents posted by 404,689 unique users. Table 1 presents the proportion of documents containing words associated with sentiments in the primary emotional subcategories (“affective processes” and “negative emotions”) as well as “drives.”



Across all quarters, negative emotions (n=383,520, 62.42%) were more prevalent than positive emotions (n=217,300, 35.37%) in “affective processes.” Within the subcategory of “negative emotions,” anxiety (n=114,234, 18.59%) and anger (n=106,767, 17.38%) were more frequent than sadness (n=23,609, 3.84%). In “drives,” risk (n=357,311, 58.15%) was the most frequently observed sentiment. Sentiments in other categories, none of which exceeded an average proportion of 50%, are presented in “S2. Sentiment analysis Details” in Multimedia Appendix 1. For instance, family (n=65,069, 10.59%) in “social processes,” insights (n=261,040, 42.48%) in “cognitive processes,” and health (n=80,967, 13.18%) in “biological processes” were the most predominant sentiments in their respective categories.

Temporal trends of sentiments are plotted in Figure 4, with the numeric results of linear regression presented in Table 1. Regarding “affective processes,” while positive emotions shows

XSL•FO
RenderX

a slight increase (β1=0.11, *P*=.004), negative emotions increased more prominently by 0.36% per quarter (*P*<.001), rising from approximately 40% to 60%, with spikes aligning with the 3 previously discussed data peaks, as indicated by black dotted lines. All sentiments in "negative emotions" display an increasing trend, with anxiety (n=114,234, 18.59%, β1=0.12%, *P*<.001) and anger (n=106,767, 17.38%, β1=0.17%, *P*<.001) showing relatively strong upward trends compared with sadness (n=23,609, 3.84%, β1=0.05%, *P*<.001). Regarding "drives," risk remained consistently above 40% and showed a noticeable increase over time (β1=0.33%, *P*<.001) relative to other sentiments. Additional analyses can be found in "S2. Sentiment Analysis Details" in Multimedia Appendix 1, indicating that insights (n=261,040, 42.48%, β1=0.25%, *P*<.001) and hear (n=87,281, 14.21%, β1=0.19%, *P*<.001) were relatively dominant and exhibited increasing trends.

Figure 4. The Japanese version of the Linguistic Inquiry and Word Count Dictionary quarterly trends in "affective processes," "negative emotions," and "drives." Black vertical dotted lines indicate the 3 major tweet peaks as illustrated in Figure 3.

Topics About Older Drivers

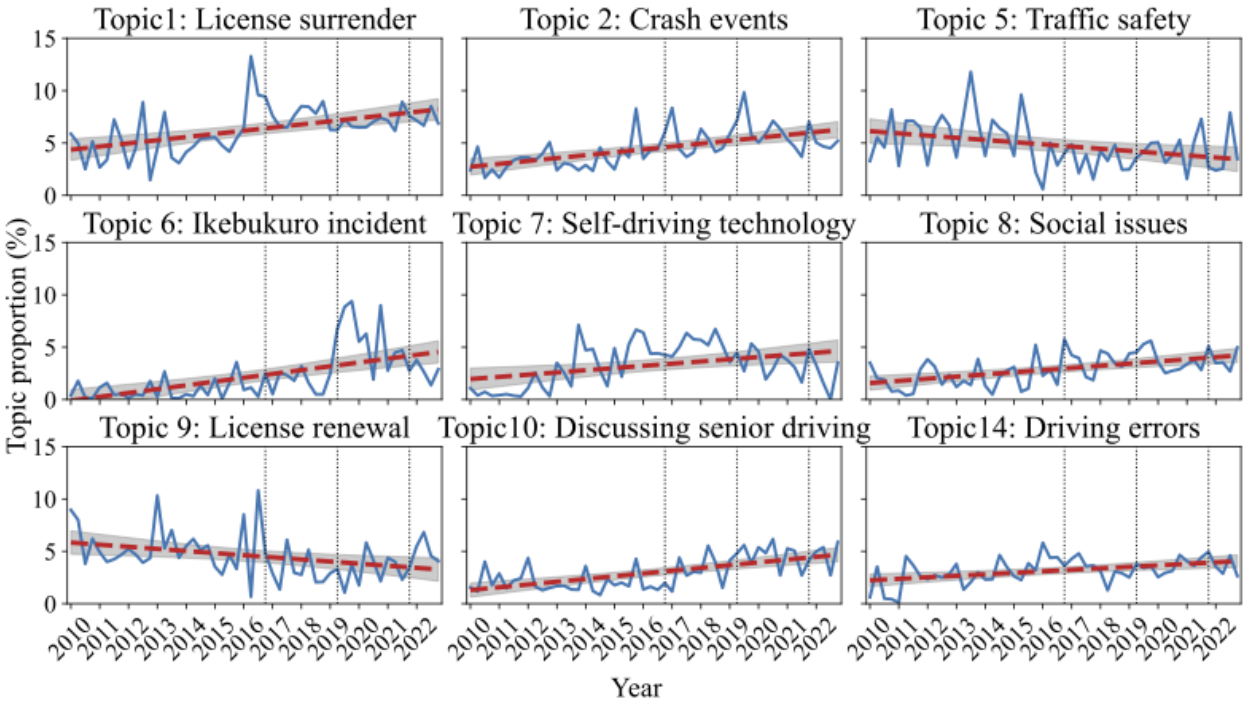
Topic modeling with 2 layers of NMF identified 29 dynamic topics that achieved the highest coherence score of 0.22 in an experiment varying the number of topics between 25 and 90 (Multimedia Appendix 1).

We further selected 16 topics that constituted at least 3.5% of all documents on average, naming them based on the top-weighted words and representative original tweets for each topic. Finally, we selected 9 topics where the R^2 value exceeded 0.1 in simple linear regression, represented by a red dashed line, as illustrated in Table 2. The details of all 16 topics, including typical tweets (in both Japanese and English), as well as the regression results for the 7 topics whose R^2 did not exceed 0.1, are provided in Multimedia Appendix 1.

Table . Description of 9 topics, including topic names, top 10 weighted words, proportions, and results of linear regression (the formula Yt=β0+β1Xt+ t).

Topic name	Top 10 weighted words	Tweets, n (%)	β0	β1	R^2	*P* value
Topic 1: License surrender	return, license, voluntary, revoke, system, forcefully, surrender, certificate, revocation, discount	43,270 (7.04)	4.37	0.08	0.278	<.001
Topic 2: Crash events	crash, cause, increase, traffic, report, death, decrease, frequent, occur, prevention	35,396 (5.76)	2.73	0.07	0.358	<.001
Topic 5: Traffic safety	traffic, safety, campaign, prevention, bicycle, drinking, nationwide, walking, public, child	25,139 (4.09)	6.13	−0.05	0.123	.010
Topic 6: Ikebukuro incident	runaway, Ikebukuro, Tokyo, NHK, defendant, crash, bereaved, family, memorial[a]	24,430 (3.98)	−0.10	0.09	0.343	<.001
Topic 7: Self-driving technology	self-driving, social, Japan, technology, necessary, safety, soon, experiment, popularization, development	24,235 (3.94)	1.95	0.05	0.151	.004
Topic 8: Social issues	issue, social, consider, life, rural, solution, necessary, difficult, traffic, local	23,935 (3.90)	1.57	0.05	0.294	<.001
Topic 9: License renewal	renewal, license, course, take, exam, test, center, excellent, Emperor, Kobe	23,525 (3.83)	5.83	−0.05	0.126	.010
Topic 10: Discussing senior driving	say, bad, hear, go, oneself, come, same, can, young, complain	23,511 (3.83)	1.30	0.07	0.402	<.001
Topic 14: Driving errors	brake, accelerator, step, mistake, wrong, pedal, crash, parking, MT[b], operation	21,741 (3.54)	2.23	0.04	0.199	<.001

[a]The frequently mentioned name of the individual involved in this crash has been masked to consider ethical concerns.



[b]MT indicates Manual Transmission, which is one type of vehicle transmission system.

XSL•FO
RenderX

The most prevalent topics were License surrender (n=43,270, 7.04%) and Crash events (n=35,396, 5.76%), followed by Traffic safety, Ikebukuro incident, Self-driving technology, Social issues, License renewal, Discussing senior driving, and Driving errors. Other topics include Thoughts on older drivers, Prevalent older drivers, and News media ("S3. Topic Modeling Details" in Multimedia Appendix 1).

Figure 5 illustrates the temporal trends of topic proportions for 9 topics with a red dashed line, representing the simple linear regression result for each topic. The proportions of topics 1 (License surrender, β1=0.08, *P*<.001), 2 (Crash event, β1=0.07, *P*<.001), 6 (Ikebukuro incident, β1=0.09, *P*<.001), 8 (Social issues, β1=0.05, *P*<.001), 10 (Discussing senior driving, β1=0.07, *P*<.001) and 14 (Driving errors, β1=0.04, *P*<.001) show consistent increases over time. Notably, topic 1 peaked in 2016, when measures to promote license surrender in rural areas gained attention. Topics 2 and 8 correspond to tweet count peaks, while topic 6 coincides specifically with the fourth quarter of 2019 subsequent periods. Although less pronounced, topic 7 (Self-driving technology, β1=0.05, *P*=.004) also exhibits an increasing trend, whereas topics 5 (Traffic safety, β1=−0.05, *P*=.01) and 9 (License renewal, β1=−0.05, *P*=.001) are declining. Additional analysis can be found in "S3. Topic Modeling Details" in Multimedia Appendix 1). Notably, News media exhibits topic peaks in the fourth quarter of 2016, reflecting unique characteristics not captured by simple linear regression.

Figure 5. Temporal trends of 9 topic mean proportions, shown as solid blue lines, with red dashed lines representing regression lines. Gray shaded areas represent 95% CIs for the regression lines. Black vertical dotted lines indicate the 3 major tweet peaks as illustrated in Figure 3.

Correlation Analysis on Sentiments

Table 3 and Table 4 present the results of the correlation analysis for positive emotions and negative emotions in "affective processes," risk in "drives" and anxiety, anger, and sadness in "negative emotions," across 4 crash rates, 2 data counts, and 9 topics. While the correlation analysis for crash rates among individuals aged more than 70 years and 80 years is based on yearly data (n=13) due to the limited availability of statistical data [14], the other analyses are based on quarterly data (n=52).

For the crash rate of individuals aged between 60 and 69 years, negative emotions (r=−0.80, P=.001) and anxiety (r=−0.82, P<.001) exhibit strong negative correlations, similar to those observed for individuals aged more than 70 years. Reversely, anger exhibits the strongest negative correlation with the youngest age group (16-29 y). Regarding the tweet count, negative emotions (r=0.68, P<.001), risk (r=0.68, P<.001), and anger (r=0.52, P<.001) exhibit moderate to strong positive correlations, similar to the user count.

For topics, topics 2 (Crash events, r=0.76, P<.001), 6 (Ikebukuro incident, r=0.55, P<.001), 8 (Social issues, r=0.71, P<.001), and 9 (License renewal, r=−0.50, P<.001) are significantly correlated with negative emotions, similar to risk. Furthermore, while positive emotions do not show significant correlations with any topic, other sentiments are correlated with multiple topics: anxiety with topics 2, 8, and 9; anger with topics 2, 6, 8, and 10 (Discussing senior driving); and sadness with topic 6.

Discussion

Principal Findings

In this study, we conducted a quantitative analysis of discourse regarding older drivers from 2010 to 2022 in Japan using Twitter. The number of tweets and users discussing older drivers has increased since 2016, with peaks observed in 2016, 2019, and 2021. Sentiment analysis revealed that negative emotions were more prevalent and increased over time compared with positive emotions. In addition, contexts related to anxiety, anger, and risk were prevalent and showed an upward trend. Topic modeling identified themes primarily related to driving licenses, crash events, personal perspectives, and traffic issues. Chronologically, despite decreasing trends in Traffic safety and License renewal, topics such as Crash events and License surrender are increasing. Finally, correlation analysis revealed that negative emotions were negatively correlated with crash rates among older drivers, positively correlated with tweet counts, and positively associated with topics such as Crash events and Ikebukuro incident.

This study quantified issues surrounding older drivers through Twitter, a leading social media platform, contributing to advancements in research on public health and ageism. The function of social media, such as posting and sharing tweets on any subject along with figures and URLs in Twitter, enables to prompt the swift dissemination of information [49] and derive population-level inferences. These have fostered new fields in public health sectors such as infoveillance [50], digital epidemiology [51], and digital disease detection [52]. They also led to an increase in health-related studies in Japan including hospitals [53], disease information [54], and eHealth literacy [55]. In addition to public health, the issue of older drivers has the aspects of ageism, which encompass our thoughts (stereotypes), emotions (prejudice), and behaviors (discrimination) toward others based on age [56]. Ageism toward

XSL•FO
RenderX

older people is especially high [57] and can adversely affect physical and mental health, such as reduced cognitive function [58], shorter life expectancy [59], deteriorated mental health [60], and increased isolation [61], prompting initiatives to counteract it [62]. Research on ageism is seen across multiple domains including health research [63], mental health services [64], long-term care facilities [65,66], workplaces [67,68], and media representations [69-71], with recent Twitter-based approaches employing thematic [72-76], descriptive [75,76], computational modeling [77,78], and quantitative text analyses [79-82]. This study, therefore, addresses the issues surrounding older drivers from both public health and ageism perspectives, contributing insights toward mitigating these challenges.

An abrupt increase in tweet counts sporadically observed over time is likely attributable to high-profile crashes caused by older drivers. The highest peak in the second quarter of 2019 corresponding to topic 6 (Ikebukuro incident) coincided with a crash that occurred in Higashi-Ikebukuro, Tokyo, drawing significant media and online attention for several months due to widespread sadness and anger toward the man, leading to the highest recorded number of driver's license surrenders in 2019 [2]. The peak in the fourth quarter of 2016, associated with topic 8 (Social issues) and topic 11 (News media) coincided with a series of crashes, and the peak in the fourth quarter of 2021, followed by a crash in Osaka, led to an increase in tweets related to topic 2 (Crash events) and topic 14 (Driving errors).

Regarding sentiments, all 3 peaks coincided with peaks in negative emotions and risk, with average proportions remaining somewhat higher after the peaks than before, while positive emotions were less relevant. Thus, the data peaks of tweets about older drivers are largely facilitated by contexts of negative emotions and risks, supported by the trends in their specific crashes aggregated by topics.

The detected topics help us understand how society forms opinions and perceptions toward older drivers in the long run. Among the 16 topics accounting for over 3.5%, we identified 7 increasing topics and 2 decreasing topics. Driving licenses are discussed in both topics 1 and 9, with public discourse increasingly focusing on license surrender (topic 1 is rising) rather than renewal (topic 9 is declining), suggesting a social shift toward discouraging older adults from driving and a potential impact on the number of license surrenders [2]. Topic 2 (Crash events), including tweets such as "It seems that crashes involving older drivers are occurring frequently" and "Let's prevent crashes involving older drivers," reflects general discussions about such events, often triggered by specific incidents, as seen in data peaks in 2016 and 2019. In contrast, topic 6 (Ikebukuro incident) includes a summary of the Ikebukuro incident and the perpetrator [46], showing a notable increase in 2019, and topic 14 (Driving errors) highlights that crashes caused by older drivers often occur due to physical or operational limitations, as shown in meta-review [4]. Over the data collection period, topic proportions shifted from topic 5 (Traffic safety; prominent until 2015) and topic 7 (Self-driving technology; high between 2013 and 2019) to topics 8 (Social issues) and 10 (Discussing senior driving), both of which have recently increased. These topics express concerns about older drivers from societal (topic 8) and family (topic 10) perspectives. Other recurring topics include Thoughts on older drivers, Prevalent older drivers, and News media, which consistently appear in this discourse. Notably, topic 11 (News media), which includes references to major media outlets, showed a high proportion between 2016 and 2017, suggesting a potential media overemphasis on older driver–related issues. (Example tweets for these and other topics not discussed in the main text are provided in "S3. Topic Modeling Details" in Multimedia Appendix 1).

Our analysis clarifies the sentiments in public discourse and their correlations, particularly negative emotion, anxiety, anger, and risk, which have shown a persistent and increasing trend over time. The proportion of documents expressing negative emotions rose from approximately 40% to 60%, accounting for an increase of 1.4% per year. This trend is strongly positively correlated with data count and with topics 2 (Crash events), 6 (Ikebukuro incident), and 8 (Social issues). In contrast, negative emotions are most significantly and strongly negatively correlated with the crash rates of older adults (aged 60-69 y and 70+ y; P=.001), although similar trends are also observed in other age groups. These suggest that negative perceptions toward older drivers arise from heightened attention to their crash events and recognition of the issue as a social problem. Similar to negative emotions, the sentiment of risk increased from 40% to 60% (1.3% per year), with peaks around 70% in 2016 and 2019. This indicates that public perception includes not only negativity toward older drivers but also a sense of danger regarding their driving. Within "negative emotions," anxiety and anger, each accounting for approximately 20%, are more prevalent than sadness. Although they do not show sharp peaks, both have steadily increased over time. While their correlation patterns are similar to those of negative emotions, stronger correlations are observed; the negative correlation between anxiety and topic 9 (License renewal) suggests decreasing focus on continued driving, while the positive correlation between anger and topic 10 (Discussing senior driving) indicates emotional overrepresentation of older drivers in discourse. Positive emotions show no significant correlation with any of the variables. Sadness, however, is correlated with topic 6 (Ikebukuro incident), suggesting compassion for the mother and child who were victims in the incident. Overall, driving by older people is increasingly perceived as negative and risky, and this perception is influenced by strong negative emotions such as anxiety and anger, which amplify public discourse on the topic despite a declining trend in their actual crash rates.

Finally, we present our perspectives. First, negative stereotypes and prevailing public sentiment toward older drivers may influence licensing policies [3]. Our analysis reveals contrasting trends between topics related to license renewal and license surrender, suggesting a shift in public perception toward encouraging older individuals to stop driving. However, this shift tends to overlook the potential adverse effects of driving cessation, as noted in previous studies [5-7]. Although analysis of the relationship between public discourse and licensing policies remains limited, it is essential to reconsider current policies that may discourage older people from driving—such as overly strict licensing requirements [4,5] and campaigns

XSL•FO
RenderX

promoting license surrender [2]—in favor of approaches that both reduce traffic crashes and ensure their safety.

Second, the disproportionate public attention given to traffic crashes involving older drivers is a significant concern. Although the anger directed at tragic crashes involving older drivers is understandable, many older individuals follow traffic laws and drive responsibly [4], therefore it is unfair that the entire older population faces negative consequences as a result. To address this, it is necessary to implement risk-based licensing policies that focus on high-risk individuals, as well as to promote autonomous driving technologies and infrastructure that support continued safe mobility for older adults.

Third, public debate following crashes involving older drivers often centers on specific high-profile incidents rather than on the overall frequency or statistical context of such crashes. This may be partly due to media tendencies to sensationalize older driver involvement, as seen in the temporary increase in topic 11 (News Media). Media use influences the formation and stability of public opinion clusters [83] and can contribute to heightened public anxiety during periods of uncertainty, such as pandemics [84]. Providing the public with a more accurate and balanced understanding of older drivers—including countering media-driven bias—is crucial to fostering constructive discourse. This may involve encouraging more responsible media reporting and promoting public access to objective information on older driver safety.

In summary, this study offers a long-term analytical approach that integrates sentiment and textual content, contributing to research on public discourse related to aging issues and, more broadly, public health. Our findings enhance the understanding of societal perceptions and policy implications surrounding older drivers in Japan and may inform future discussions on aging societies around the world.

Limitations

Our study had several limitations. First, while Twitter is one of the most widely used social media platforms in Japan [85], Twitter users do not necessarily represent the general population [86]. Furthermore, Twitter provides access only to tweets from public accounts, deterring extreme or controversial textual content to be tweeted or we might have missed such tweets because past tweets can be deleted. In addition, display algorithms were modified around 2011 due to a rapid increase in Twitter users, resulting in nonstationarities in the dataset. To mitigate such user biases, several approaches have been proposed, including evaluating users based on the authenticity and bias of their engagements [87], and accounting for population demographics and word ambiguity [88].

Second, while the keyword (“(高齢 OR 老人) AND (運転 OR ドライバー)” in Japanese) effectively targets discussions about older drivers, there is still room for refinement. “運転” (driving) and “ドライバー” (driver) are the words related to driving, representing specifically older driving by combing words “高齢” (denoting old age) or “老人” (denoting older people). Although adding “事故” (crash) was considered, this word could collect data unrelated to crashes like falls in daily life, without words related to driving. Other age-related words like “80歳のドライバー” (80-year-old drivers) or “祖父” (grandfather) specify too detailed ages or familial relations, which are less general and more restrictive, so we did not use them aligning with our research objectives. In addition, we found that a small portion (33 out of 1000) of the sampled tweets were not related to older drivers but represented older people in nondriving contexts such as riding the bus or being crash victims. Therefore, while the data from this study appears to be sufficiently valid, there is a need to refine the keyword or explore other methods to collect more accurate data on older drivers.

Third, our methods have room for improvement. Word-based approaches for sentiment analysis and topic modeling offer valid and intuitive interpretations for emerging themes such as older driver–related discourse, but they may not fully capture contextual nuances such as negations or compound expressions. Although the J-LIWC dictionary covered 48% (4458 out of 9287) of the words used in this study—indicating substantial coverage with room for refinement—our findings remain persuasive, especially when compared with the Japanese version of the Moral Foundations Dictionary [89], which covers only 3% (275 words) (“S3. Sentiment Analysis Details” in Multimedia Appendix 1). Furthermore, the coherence score for the dynamic topic model was 0.22, lower than the commonly accepted baseline of 0.36 [36]. This may be influenced by the linguistic characteristics of Japanese and the use of a Japanese word2vec model. Finally, as correlation analysis does not imply causation, more rigorous statistical testing is needed. Therefore, although our word-based method using reliable dictionaries offers high interpretability, future work should explore alternative methods—such as deep-learning–based sentiment analysis or BERTopic for topic modeling—and incorporate techniques like supervised machine learning or community detection to gain deeper insights [24,41,90,91].

Conclusions

Despite the actual decline in crash rates among older drivers, previous surveys in Japan reveal persistent negative sentiments toward them, suggesting the need to understand discourse on social media, which serves as a platform for public debate. To quantitatively assess public awareness, we collected and analyzed tweets related to older drivers. The results revealed an increase in the number of tweets from 2010 to 2022, with certain peaks aligning with heightened attention to crashes involving older drivers. Negative emotions and risk consistently displayed high and rising levels, primarily correlated with the topic of crash events. Furthermore, there are diverse topics related to drivers’ licenses, crash events, and traffic safety. These imply unfair public recognition toward older drivers, suggesting the need for reconsidering current license policies, promoting self-driving systems, and facilitating accurate and balanced understanding, in order to provide continued safe mobility for older adults.

Abstract

Background: The opioid crisis poses a significant health challenge in the United States, with increasing overdoses and death rates due to opioids mixed with other illicit substances. Various strategies have been developed by federal and local governments and health organizations to address this crisis. One of the most significant objectives is to understand the epidemic through better health surveillance, and machine learning techniques can support this by identifying opioid users at risk of overdose through the analysis of social media data, as many individuals may avoid direct testing but still share their experiences online.

Objective: In this study, we take advantage of recent developments in machine learning that allow for insights into patterns of opioid use and potential risk factors in a less invasive manner using self-reported information available on social platforms.

Methods: This study used YouTube comments posted between December 2020 and March 2024, in which individuals shared their self-reported experiences of opioid drugs mixed with other substances. We manually annotated our dataset into multiclass categories, capturing both the positive effects of opioid use, such as pain relief, euphoria, and relaxation, and negative experiences, including nausea, sadness, and respiratory depression, to provide a comprehensive understanding of the multifaceted impact of opioids. By analyzing this sentiment, we used 4 state-of-the-art machine learning models, 2 deep learning models, 3 transformer models, and 1 large language model (GPT-3.5 Turbo) to predict overdose risks to improve health care response and intervention strategies.

Results: Our proposed methodology (GPT-3.5 Turbo) was highly precise and accurate, helping to automatically identify sentiment based on the adverse effects of opioid drug combinations and high-risk drug use in YouTube comments. Our proposed methodology demonstrated the highest achievable F_1-score of 0.95 and a 3.26% performance improvement over traditional machine learning models such as extreme gradient boosting, which demonstrated an F_1-score of 0.92.

Conclusions: This study demonstrates the potential of leveraging machine learning and large language models, such as GPT-3.5 Turbo, to analyze public sentiment surrounding opioid use and its associated risks. By using YouTube comments as a rich source of self-reported data, the study provides valuable insights into both the positive and negative effects of opioids, particularly when mixed with other substances. The proposed methodology significantly outperformed traditional models, contributing to more accurate predictions of overdose risks and enhancing health care responses to the opioid crisis.

Introduction

Background

Opioid overdose occurs when someone takes an excessive amount of prescribed or illicit drugs, such as heroin or fentanyl, which can cause potentially life-threatening symptoms by interacting with receptors in the brain and nervous system to reduce pain. Chronic pain, one of the leading causes of disability and overall disease burden worldwide [1,2], is a significant factor in the increasing use of opioid drugs mixed with illicit substances, with an estimated 20%-30% of the global population experiencing chronic pain [3,4]. The annual economic impact of chronic pain ranges from US $560 to $635 billion in the United States [5-7]. The challenging nature of chronic pain makes it one of the most persistent medical issues, presenting various diagnostic and treatment difficulties [8]. In the pharmacological management of chronic pain, opioids have long been considered essential medications for patients. Although their effectiveness in treating serious pain is generally

XSL•FO
RenderX

accepted, the use of opioids for chronic pain remains controversial due to long-term side effects such as tolerance and dependence [9,10]. These issues, along with prescription and misuse, have contributed to a significant global health crisis known as the opioid crisis [11], which has resulted in approximately 500,000 overdose deaths in the United States, with nearly 70,000 fatalities reported in 2020 alone [12].

In recent years, sentiment analysis has attracted exponential interest from researchers. The growing number of scientific publications, forums, and related conferences highlights its potential for future development. Social media platforms such as X (formerly known as Twitter), Facebook, Instagram, Reddit, and YouTube play a key role in this expansion, with over 58% of the world's population actively sharing their opinions, experiences, and concerns on these platforms [13]. These platforms provide researchers with valuable insights into health determinants by allowing the analysis of lifestyle choices, habits, and personal experiences. Social media's role in medical research is profound as it enables real-time global observations of important clinical topics, including influenza spread, suicide risk factors, and substance use trends [14-19].

Recent advances in natural language processing (NLP) have facilitated large-scale social media data analysis, making significant contributions to fields such as suicide risk detection, adverse drug reaction identification, and misinformation classification [20-22]. However, there remains a notable gap in applying key phrase extraction techniques to self-reported health-related content on social media, particularly within online health communities. The rise of web-based health care platforms has propelled automatic sentiment analysis of medical reviews into a new era of data-driven insights. This method allows researchers to analyze vast amounts of web-based user-generated data, uncovering hidden patterns about the side effects of opioid drugs. These insights are crucial for refining pharmacovigilance programs, ensuring drug safety and effectiveness. Over time, sentiment analysis in NLP has evolved significantly, enabling more accurate and meaningful interpretations of user experiences with medicines [23,24].

Prior Work

Recent years have witnessed the trend of studying opioid use disorders using social media data such as YouTube comments, X, and Instagram. Social media platforms have become essential for analyzing user-reported experiences with opioid drugs, particularly when mixed with illicit substances, as they offer valuable insights into drug use behaviors and potential overdose risks.

Carabot et al [25] used state-of-the-art machine learning (ML) models on Twitter posts related to opioid drugs. They collected a dataset from January 1, 2019, to December 31, 2020, focusing on user experiences and perceptions of these drugs. They gathered a total of 256,218 Twitter posts. They used preprocessing techniques, and only 27% of the tweets were filtered out, which shows relevancy; after preprocessing, they conducted a manual analysis of 7000 tweets using a detailed codebook. They classified users as patients, health care professionals, or institutions and distinguished between medical and nonmedical content. The findings showed that fentanyl was the most discussed opioid, with patients dominating the conversation, while health care professionals' tweets garnered the most engagement.

Swaileh et al [26] explored sentiment analysis in NLP to improve the understanding of public health and medication experiences. They used a hybrid model that combined traditional methods with advanced ML. Their proposed methodology achieved a high accuracy of 99% in sentiment classification. Their goal was to improve pharmacovigilance and inform public health initiatives by analyzing user feedback on health care and medications.

Chenworth et al [27] conducted a study to analyze public perceptions of methadone and buprenorphine-naloxone (Suboxone) through Twitter posts. They performed manual and automatic analyses, identifying common themes such as access, stigma, and treatment, with limited positive sentiment about the medications. Despite their proven effectiveness, the study suggests that public perceptions may contribute to the underutilization of these treatments for opioid use disorder.

Al-Hadhrami et al [28] explored the performance of deep learning (DL) techniques including bidirectional long short-term memory (BiLSTM) and a hybrid BiLSTM convolutional neural network (CNN) for sentiment analysis of drug-related reviews. They used Global Vectors for Word Representation (GloVe) word embedding methods and achieved an accuracy rate of 96%. The results underscore the enhanced performance of these models in analyzing patient sentiments, demonstrating the value of DL techniques in this context.

Chakrapani et al [29] discussed the challenge of analyzing the mindset of patients affected by acute diseases by introducing a framework that uses a sociomedical dataset of reviews and feedback. They used preprocessing techniques, n-gram tokenization, and polarity scoring to extract sentiments, followed by a probabilistic latent Dirichlet allocation model for review aggregation. They applied various ML models and evaluated the performance of the models in understanding patient perspectives.

Nair et al [30] focused on creating a drug review classification system to label user reviews into multiple classes, such as positive, negative, and neutral, by using publicly available datasets from drugs.com. They applied 3 variants of the pretrained bidirectional encoder representations from transformers (BERT) model, namely mBERT, SciBERT, and BioBERT, to generate embeddings used as features for various ML classifiers, including decision trees (DTs) and DL models. Model performance was assessed using precision, recall, and F_1-score metrics.

Gandy et al [31] assessed the efficacy of 3 automated sentiment analysis tools—VADER, TEXT2DATA, and LIWC-22—against manually labeled datasets of YouTube comments related to opioid epidemics. The LIWC-22 model achieved the highest accuracy with an 88% F_1-score, whereas VADER achieved 83%, and TEXT2DATA achieved 82%. The results suggest that these models can be effectively applied to social media analyses.

XSL•FO
RenderX

Although prior studies have used state-of-the-art ML and NLP models for opioid-related research, they often focused on basic sentiment classification such as positive and negative opinions and did not consider detailed discussions about mixed drug use. Many previous models did not include the many ways drugs can be mixed or their effects, which is essential for fully understanding opioid misuse. Unlike past studies, our research introduces a unique multiclass methodology with 6 different categories, including a mix of opioids and other substances. This classification captures the complexity of real-world drug use, which other studies may overlook. By using a large language model (LLM), we can better study and sort these mixed-drug experiences, detecting subtle feelings and trends that older models cannot. Our approach does more than just basic sentiment analysis. It overcomes the weaknesses of past models and gives a clearer, more complete picture of opioid misuse.

Objective

This study aims to validate a methodology that uses YouTube video comments for sentiment analysis, focusing on instances where people discuss opioid drug use mixed with other substances, increasing the risk of overdose and adverse effects. By using advanced NLP techniques and LLMs such as GPT-3.5 Turbo, this research seeks to uncover hidden patterns and derive meaningful insights from discussions about drug use. Although the information shared on social media platforms can provide valuable insights into individual experiences, it is important to note that these platforms do not directly reflect the cause and usage situations in real-world settings. Despite the high penetration of social media, the data derived from these sources cannot always be used to determine the full context of opioid misuse, overdose, or adverse effects in the real world. Unlike traditional studies that focus solely on sentiment classification, our approach directly contributes to health care by identifying high-risk behaviors and potential opioid misuse patterns, such as the combination of opioids with other substances that significantly increase overdose risk. By analyzing both the emotional tone and detailed drug use experiences, our work aims to empower public health organizations with actionable intelligence to address emerging drug trends proactively and uncover risk factors linked to the misuse of opioids, including adverse physical effects and emotional responses, which could inform public health interventions. The use of ML, DL, and LLMs such as GPT-3.5 Turbo is critical for detecting subtle patterns within large amounts of social media data, which can be difficult to identify manually. Although social media platforms do not directly reflect the full context of opioid misuse or overdose situations in the real world, these advanced techniques enhance our ability to derive accurate and actionable insights from online discussions about opioid misuse, ultimately improving patient outcomes and informing intervention strategies. Although social media data cannot fully capture the complexities of real-world usage, these techniques enable the identification of emerging risks and behavioral trends that might otherwise go unnoticed. This approach facilitates faster responses to public health concerns, enhances community safety, and minimizes reliance on manual intervention by providing comprehensive, data-driven analyses.

To achieve these objectives, we developed a meticulously curated, multilabeled corpus, where each comment was manually annotated to reflect observed adverse effects related to opioid use. The dataset encompasses 6 distinct sentiment categories, including both positive experiences (eg, pain relief, euphoria, relaxation) and negative outcomes (eg, nausea, sadness, and respiratory depression). The selection of these 6 categories was driven by a need to capture the full spectrum of user experiences, both favorable and adverse, when discussing opioid use. By including both subjective emotional states and physical effects, we can gain a more comprehensive understanding of how different opioids impact individuals. This classification approach also supports the creation of precise, targeted interventions aimed at improving health outcomes, as it allows for the identification of both beneficial and harmful patterns in opioid usage.

Contributions

This paper makes the following contributions to the literature.

We applied the schema to build a comprehensive dataset for sentiment analysis that contains opioid mixed with illicit drugs for health care professionals, accurately annotated with high-quality labels able to identify high-risk behaviors and develop targeted interventions.

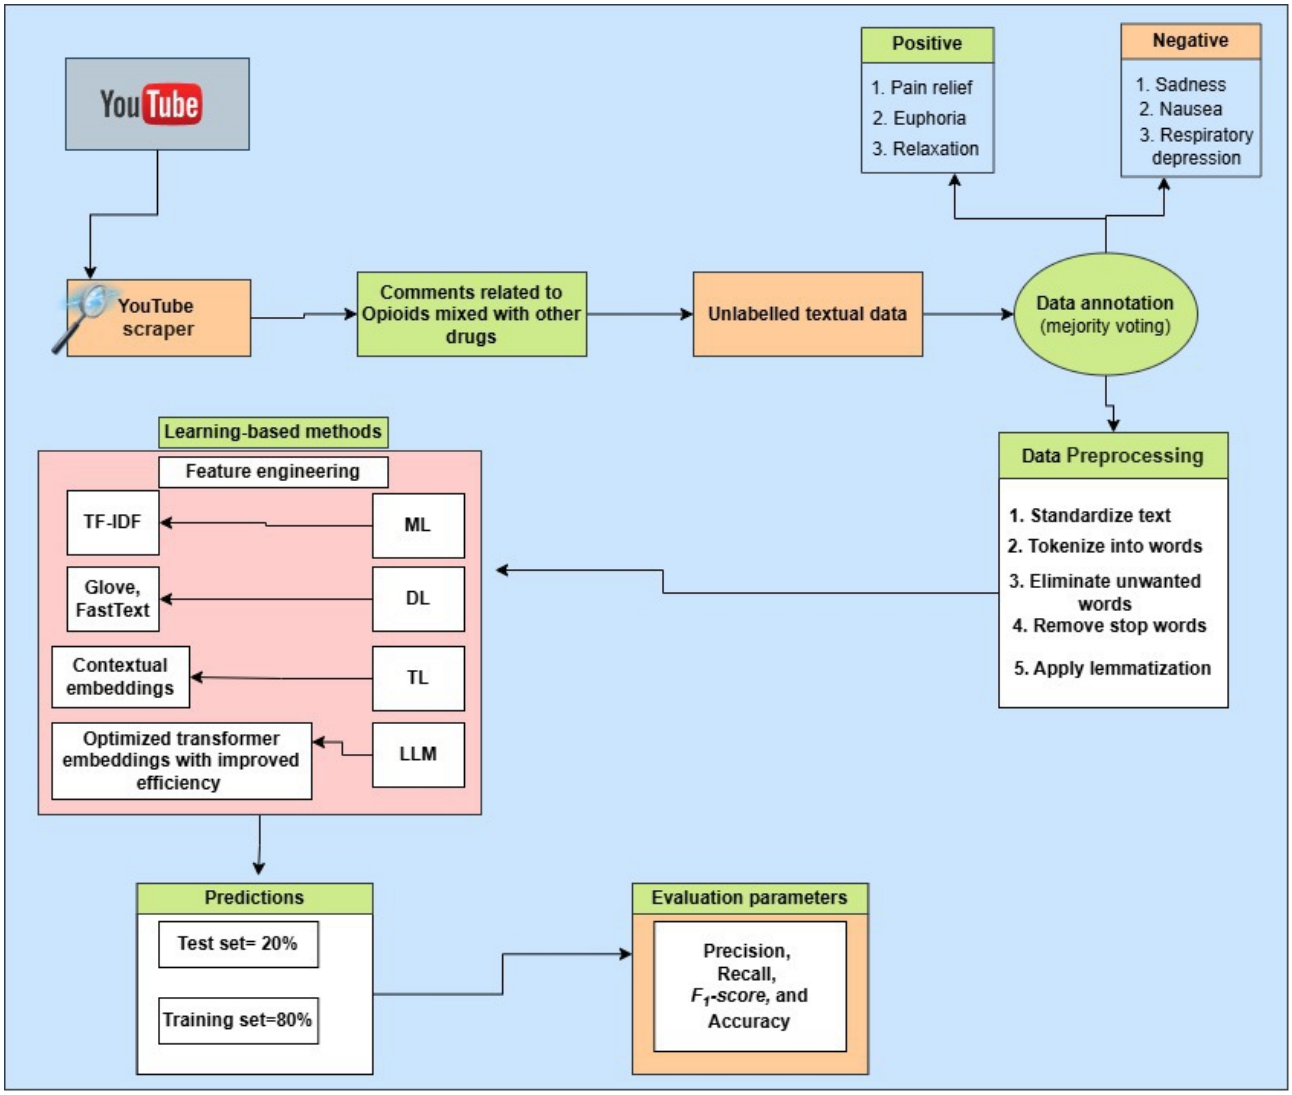
We trained and tested an LLM (GPT-3.5 Turbo) on YouTube comments where people discuss using opioid drugs mixed with other substances that can cause death. This approach provides health care professionals and policymakers with real-time, data-driven insights into opioid use trends, enabling better response strategies and prevention measures.

We conducted a comprehensive series of experiments that demonstrated that the proposed methodology achieved the best performance compared to the baseline.

The proposed framework (GPT-3.5 Turbo) demonstrated an F_1-score of 0.95 in multiclass to our dataset. This represents performance improvements of 3.26% in F_1-score compared to the baseline model (extreme gradient boosting [XGBoost] demonstrated an F_1-score of 0.92).

By bridging the gap between social media sentiment analysis and health care research, this study highlights how NLP-driven methodologies can contribute to public health strategies, improve patient safety, and enhance health care delivery. However, while NLP models can significantly assist in trend identification and risk assessment, human oversight remains crucial in interpreting results and implementing appropriate public health interventions.

Methods



Overview

This section outlines the methodologies used to create a robust sentiment analysis system. Initially, the research design is presented in a descriptive manner, with detailed explanations provided for each component in the flow diagram (Figure 1). The methodology includes multiple phases: (1) construction of dataset, (2) annotation guidelines, (3) annotation selection, (4)

XSL•FO
RenderX

annotation agreement, (5) preprocessing and analysis of the data, (6) features extraction, and (7) application of models and training and testing.

Figure 1. Architecture of proposed solution. DL: deep learning; LLM: large language model; ML: machine learning; TL: transfer learning.

Construction of Dataset

This section outlines the construction of our dataset for sentiment analysis related to opioid overdose discussions on YouTube. First, we selected videos with more than 10 million views that were related to opioid overdose to ensure that the video had a sufficient number of comments discussing the mixing of opioid drugs with other substances. For inclusion, we selected videos based on their relevance to opioid misuse, focusing on videos with clear and significant discussions of opioid drugs mixed with other substances. We excluded videos with irrelevant content, off-topic discussions, or those lacking substantial user comments on opioid misuse and its adverse effects. For data selection, we chose videos from 2020 to 2024. One of the reasons for selecting YouTube comments from this time period was to capture recent discussions in which individuals shared their fresh experiences, especially during the COVID-19 pandemic when opioid misuse surged and individuals turned to social media more frequently to share their personal experiences. We used 20 different opioid-related keywords, such as “kratom,” “fentanyl,” “heroin,” “codeine,” and “buprenorphine,” to filter the relevant samples and drug occurrences and their adverse effects as reported by opioid users. Second, we prepared a code using the YouTube application programming interface in Python, which allowed us to collect approximately 300,000 comments from different videos that reflect self-reported and personal experiences shared by users. For this study, we selected only English-language videos and comments. Third, we manually categorized the dataset into 6 sentiment categories based on the adverse effects shared by the user, ensuring a more accurate and context-sensitive classification than traditional autoannotated methods. Unlike automatic annotation techniques, which often struggle to capture the complexity of user experiences, our manual categorization process allows for a deeper understanding of the nuanced nature of opioid use and its associated effects. By classifying the dataset into sentiment categories, we aim to develop a robust model capable of understanding both the sentiment of user concern and the adverse effects they report. This manual approach ensures high accuracy and precision, which is crucial for identifying patterns related to opioid misuse and overdose risks. An example structure of the dataset, showing sample entries

XSL•FO
RenderX

and classifications, is presented in Table 1 (see annotation guideline section). Figure 1 illustrates the proposed methodology and design used in this study, highlighting the contributions of this more detailed, context-aware classification method.

Table . Samples from the dataset.

Comment text	Sentiment
I felt this amazing rush of happiness, like everything was perfect for a few hours. I know it's risky, but nothing else makes me feel that alive.	Euphoria
The pain was unbearable, so I mixed a little extra with my regular dose. It worked for the pain, but I feel uneasy about it – I know it's dangerous.	Pain relief
After mixing opioids with alcohol, I could barely breathe; it was like my chest was weighed down. Scariest experience of my life.	Respiratory depression
I thought it would help me forget, but all it did was make me feel numb and more alone. It's not worth the spiral I'm in now	Sadness
Just a small dose with some weed, and I felt completely at ease, like I didn't have a care in the world. It's tempting to keep doing it, but I worry about the risks	Relaxation
I thought it would help me unwind, but instead, I felt so sick. I could barely keep anything down, and it just wasn't worth it	Nausea

Annotation Guidelines

After the collection of data, we accurately classified the samples related to opioid overdose drugs to gain insights into public sentiment. Each sample was labeled using predefined criteria, allowing us to classify based on the effects of drugs, including positive (pain relief, euphoria, relaxation) and negative experiences (nausea, sadness, and respiratory depression). Furthermore, the categorizations of posts are presented in Table 1 and the annotation rules are listed here:

1. Full comment reading: Mark only after reading the full comment carefully. Skim-reading will be not allowed.
2. Annotation consistency: Use accurate labels as defined in these guidelines. Any deviation, such as "Maybe" or "Unclear," is not permitted.
3. Data quality check: Annotators must verify their annotated labels before finalizing as it is a necessary step to ensure accuracy and consistency.
4. Out-of-scope content: If a YouTube sample is off-topic, such as spam or irrelevant content, mark it as "Not applicable" and remove it from the corpus.
5. Pain relief: If a sample mentions opioids or mixing other substances with opioids providing relief from physical pain, including chronic pain or injury-related pain, label it as pain relief.
6. Euphoria: If a sample demonstrates a sense of joy, bliss, or intense well-being after using opioids or opioid mixtures, label it as euphoria.
7. Relaxation: If a sample mentions the relaxing, soothing, or sedative effects of opioids or opioids leading to relaxation from stress and anxiety, mark it as relaxation.
8. Nausea: Samples that indicate feeling sick or queasy or vomiting after using opioids or other drugs mixed with opioids should be marked as nausea.
9. Sadness: Samples that indicate feelings of hopelessness or emotional downers linked to opioid use or other mixtures with opioids are marked as sadness.
10. Respiratory depression: Samples that indicate difficulty breathing or a sense of being unable to breathe properly, often as a result of opioid use, should be marked as respiratory depression.

Annotation Selection

Identifying sentiment analysis in multiclass was not an easy task; it presented significant challenges. Each of these classes added another layer of complexity, requiring annotators to carefully interpret and distinguish nuanced information within the text. This made it crucial to select annotators with strong analytical skills and attention to detail. To ensure high-quality labeling for our research, we carefully selected 5 students with strong backgrounds in annotation and ML. The selected candidates were postgraduate students in computer science. We assigned 300 comments to each candidate to label the dataset; separate Google sheets were created for individuals to record their work, which allowed us to track and evaluate their performance individually. After reviewing the results, 3 of the candidates consistently agreed on the same labels across most comments, demonstrating a high level of reliability and accuracy. Based on these results, these candidates were finalized for the full annotation of this dataset.

Annotation Agreement

During the annotation process, variations in opinion arose among annotators. It is essential to analyze these inconsistencies effectively. This evaluation was carried out by calculating the interannotator agreement, which measures the quality and consistency of the annotation process. For our annotation procedure, we used the Fleiss κ statistic to determine this agreement. Fleiss κ is particularly useful when dealing with 3 or more annotators and categorical output labels. In our case, the value of κ was found to be 0.79, suggesting substantial agreement between annotators, as it falls within the range of 0.61 to 0.80. Table 2 provides the full interpretation of κ values.

XSL•FO
RenderX

Table . Interpretation of κ values for agreement between annotators.

κ value	Interpretation
<0	Less than chance agreement
0.10 - 0.20	Slight agreement
0.21 - 0.40	Fair agreement
0.41 - 0.60	Moderate agreement
0.61 - 0.80	Substantial agreement
0.81 - 0.99	Almost perfect agreement

Ethical Considerations

This study used secondary data comprising publicly available, user-generated content collected from Reddit to analyze public sentiment on opioids mixed with other substances. The data were obtained from existing, publicly accessible Reddit posts that do not contain any personally identifiable information. All content was anonymized and analyzed in aggregate to ensure the privacy and confidentiality of individuals.

There was no direct interaction with Reddit users, and no attempt was made to trace or reidentify individuals. Given that the study involved only the analysis of publicly available data, with no human subject intervention or collection of private or identifiable information, institutional review board approval was not required.

Data Preprocessing

YouTube is a video-based social networking platform where video descriptions and comments often contain URLs, hashtags, emoticons, misspelled words, internet slang, and informal grammar expressions. In this context, data preprocessing is crucial to improving text quality, making it suitable for ML models and enhancing overall model performance, especially for sentiment analysis. For traditional ML models such as DTs and XGBoost, we applied standard preprocessing steps, including text normalization by converting all text to lowercase, removing extra spaces and newline characters, tokenizing the text into individual words, and filtering out nonalphanumeric characters. Additionally, stop words were removed using a predefined list, words shorter than 3 characters were discarded, and lemmatization was applied to ensure consistency by reducing words to their base forms. However, for DL models and transformer-based architectures such as GPT-3.5 Turbo, we avoided unnecessary preprocessing steps like tokenization, stop word removal, and term frequency-inverse document frequency (TF-IDF) transformations, as these models are designed to process raw text input directly using their own internal mechanisms for text representation. Instead, we only performed minimal cleaning (removing URLs, special characters, and excessive punctuation) to maintain linguistic integrity while reducing noise. This ensures that transformer-based models fully leverage their contextual embeddings, improving sentiment classification accuracy while preventing the loss of valuable textual information.

Data Augmentation

To enhance the performance and robustness of our proposed models, we used the back translation technique for data augmentation. For the translation process, we used the Google Translate application programming interface, which offers broad language support and high-quality translations. To handle large volumes of text efficiently, we developed custom scripts that automated the translation process. After back translation, we conducted a manual quality check on a sample of the augmented data to ensure that the original meaning was retained and that no significant information was lost during the translation.

Dataset Statistics

Multimedia Appendix 1 depicts a word cloud comprising keywords extracted from posts in the dataset related to the topic of opioid overdose. The word cloud visually highlights the most frequent terms, emphasizing the critical themes discussed in the dataset. Multimedia Appendix 2 illustrates the distribution of labels for each class used in the corpus for sentiment analysis. The chart visually represents the frequency of each sentiment class in the dataset. Multimedia Appendix 3 provides an overview of the text data's structure. It shows that the dataset contained a total of 10,129,795 characters and had a vocabulary size of 31,893 unique words. On average, each sentence had 21.39 words, and each post contained 5.02 sentences. The average post length was 541.32 characters. Additionally, each word had an average of 4.86 characters. These values give a clear picture of the dataset's complexity, showing how detailed and varied the posts are in terms of sentence and word length.

Feature Extraction

After cleaning the text, the next step was feature extraction, where we converted text into numerical form for the ML models. In traditional ML, we used TF-IDF, as shown in Equations 1 and 2, which assigns importance to words based on their frequency in a document and rarity across the dataset. This helps highlight key terms for sentiment analysis. For DL, we used GloVe and FastText embeddings, as shown in Equations 3 and 4. GloVe creates fixed vector representations based on word co-occurrence in large text collections, capturing meaningful relationships between words. FastText improves upon this by considering subword information, which helps in understanding rare and misspelled words, making the model more robust. For transformer-based models and LLMs, we used pretrained embeddings from models like BERT and ChatGPT. These models capture deep contextual meanings by analyzing entire sentences rather than individual words. Unlike traditional

XSL•FO
RenderX

methods, transformers dynamically understand context, improving sentiment analysis accuracy by recognizing complex language patterns.

(1)TF=Number of times a term appears in a document/Total number of terms in the document

The inverse document frequency of a term reflects the inverse proportion of documents that contain that term. Terms with technical jargon, for example, hold greater significance compared to words found in only a small percentage of all documents. The inverse document frequency can be computed using Equation 2:

(2)IDF=Number of documents in the corpus/Number of documents in the corpus containing a term

TF-IDF can be calculated using Equation 3:

$$(3)\mathrm{TF}-\mathrm{IDF}=\mathrm{TF}\times\mathrm{IDF}$$

FastText extends Word2Vec by representing words as bags of character n-grams. The embedding for a word w is calculated using Equation 4:

$$(4)\mathrm{Vw}=\sum g\in \mathrm{G(w)Vg}$$

Where:

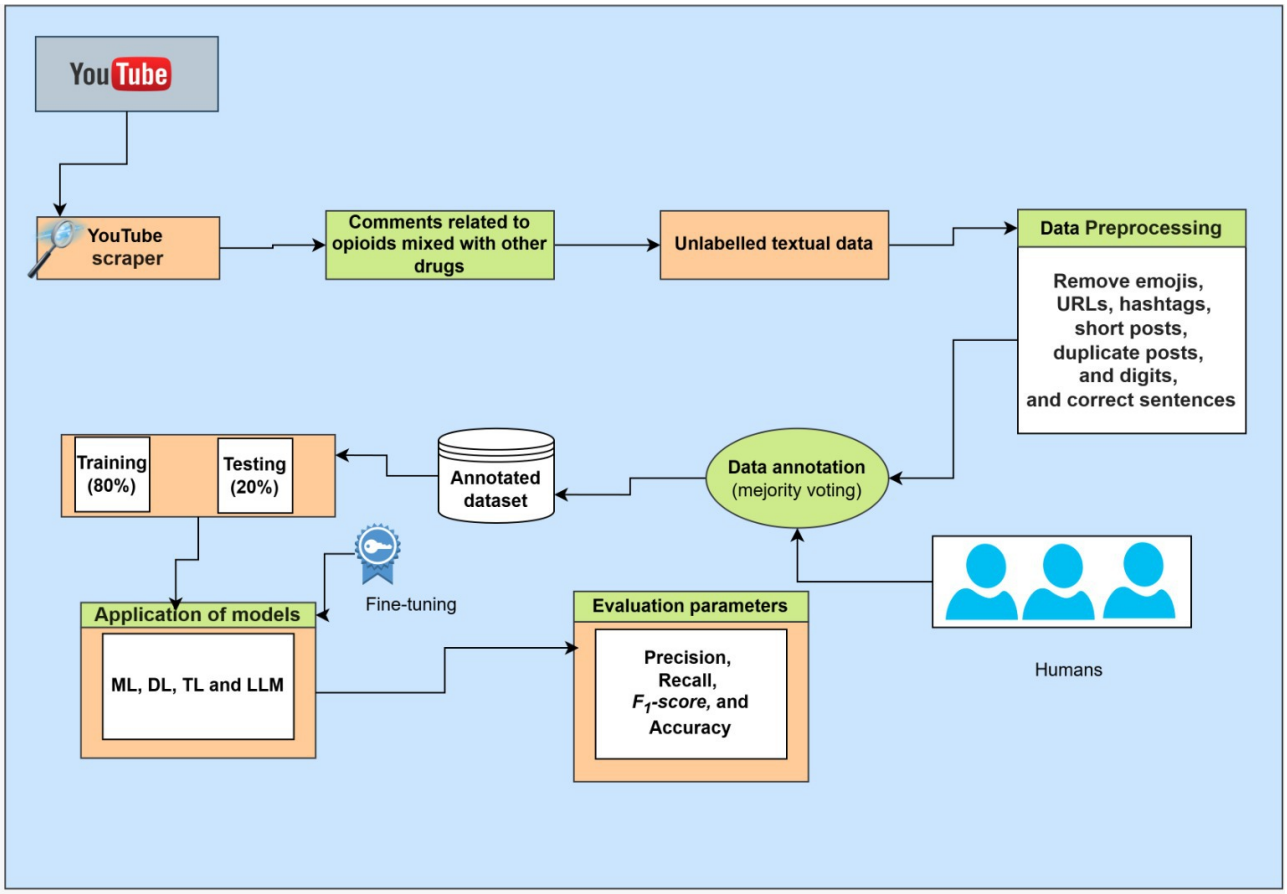
- A set of character n-grams in the word w.
- Vg is the vector representation of each n-gram g.

This allows FastText to generate embeddings for out-of-vocabulary words by combining the embeddings of their character n-grams.

GloVe creates word embeddings based on the co-occurrence matrix of words. Equation 5 is derived from the ratio of co-occurrence probabilities.

$$(5)\mathrm{Cost}=\sum \mathrm{i,jVf(Xi,j)(ViTVj+bi+bj-log(xi,j))2}$$

Where:



- $X_{i,j}$ is the number of times word j occurs in the context of word i.
- V is the vocabulary size.
- V_i and V_j are the embeddings for words i and j.
- b_i and b_j are bias terms for the words.
- $f(X_{i,j})$ is a weighting function to downweight the influence of very frequent words.

Application of Models and Training and Testing

In this section, we discuss the application of various models including ML models, DL models, transformer-based models, and LLMs such as GPT-3.5 Turbo. After feature extraction, the data were split into training and testing sets. The training set was processed to train ML algorithms including support vector machine (SVM), logistic regression (LR), k-nearest neighbor (KNN), and XGBoost, as well as 2 DL models (CNNand BiLSTM), 2 pretrained transformer models (BERT and GPT-2), and 1 LLM (GPT-3.5 Turbo). To accomplish this objective, we randomly partitioned the dataset into 80% for training and 20% for testing, as shown in Figure 2, which illustrates the ML-, DL-, and LLM-based model training pipeline for multiclass text classification. These approaches were evaluated using recall, precision, and F_1-score to quantify the performance of the models. We calculated these metrics using the following equations.

XSL•FO
RenderX

Figure 2. ML-, DL-, and LLM-based model training pipeline for multiclass text classification. DL: deep learning; LLM: large language model; ML: machine learning; TL: transfer learning.

Precision: The total number of correct predictions in our model was retrieved during document retrieval.

Recall: This indicates the classifier's ability to identify all relevant instances in the dataset.

F_1-score: The F_1-score is a metric that combines precision and recall.

Equation 8 was used for F_1-score, while Equations 6, 7, and 9 were used for precision, recall, and accuracy, respectively:

(6)Precision=TPFP+TP

(7)Recall=TPFN+TP

(8)F1− score=2× Recall ×PrecisionRecall+ Precision

(9)Accuracy=TP+TNTP+TN+FP+FN

Where TP is true positive, TN is true negative, FP is false positive, and FN is false negative.

Results

Overview

This section discusses the results derived from the methodology, implementation, and experiments outlined earlier. For ML models, we used GridSearchCV for hyperparameter optimization, testing parameters such as regularization (eg, C and gamma for SVM), penalty terms for LR, and boosting-related settings like learning rate, number of estimators, and maximum tree depth for XGBoost. For KNN, we tuned parameters like the number of neighbors and weight functions. In the case of DL models, adjustments were made to epochs, batch sizes, and learning rates to fine-tune the BiLSTM and CNN architectures for optimal performance. For transfer learning models, fine-tuning involved modifying pretrained weights and adapting hyperparameters such as learning rates, sequence lengths, and transformer-specific configurations to improve BERT and GPT-2 on the dataset. Each model's performance was systematically optimized by fine-tuning its parameters to maximize its effectiveness. A comprehensive overview of the hyperparameters and grid search used in the proposed approach is provided in Table 3.

XSL•FO
RenderX

Table . Optimum values identified for the hyperparameters of each learning approach.

Learning approach and models		Hyperparameter	Fine tuning pipeline
Large language model: GPT-3.5 Turbo		Learning rate, epoch, batch size, seed	2, 3, 29, 1414121048
Transformer: bidirectional encoder representations from transformers, RoBERTa, crosslingual language model – RoBERTa		Learning rate, epoch, batch size, optimizer, loss function	2e-5, 3, 32, AdamW, CrossEntropy-Loss
Machine learning			
	K-nearest neighbors	n_neighbors, weights	5, uniform
	Extreme gradient boosting	n_estimators, max_depth, learning_rate	100, 6, 0.3
	Decision tree	random_state, max_depth	42, 10
	Logistic regression	random_state, max_iter, C, solver	42, 1000, 0.1, liblinear
Deep learning: bidirectional long short-term memory and convolutional neural networks		learning rate, epoch, embedding_dim, batch size,	0.1, 3, 300, 32

Software and Hardware

Experiments were conducted on a Lenovo laptop powered by an Intel Core i7, 8th generation processor with 4 cores, bus speed of 8 gigatransfers/second, 24 GB of RAM, and 1 TB of storage. The operating system used was Windows 10 Pro (Microsoft Corp), which provided a stable environment for development and execution. To perform the predictive analysis, Google Colab was selected for programming and easy access to a Python environment. We used Python version 3.12.4. The *Scikit-Learn* [32] package was used for ML models, while *TensorFlow* [33] and *Keras* [34] were used for DL tasks. For transformer-based models, the Hugging Face Transformers library was used. Model training was performed on an NVIDIA Tesla T4 GPU with 2560 CUDA cores and 16 GB GDDR6 memory.

Results for ML

In this section, we will explore the performance of several traditional ML models applied to sentiment analysis, specifically focusing on the complex topics of opioid overdose and drug mixing with other substances. To tackle this, we used 6 models including LR, KNN, random forest, and SVM. Each model was evaluated to understand how well it can detect sentiment in this sensitive area, aiming to identify patterns and nuances within the data related to drug use.

Table 4 shows the performance metrics of 4 different ML models: LR, DT, KNN, and XGBoost. We used 4 different evaluation metrics to assess the performance of these models including precision, recall, F_1-score, and accuracy. Among all models, XGBoost achieved the highest scores on all metrics (0.92 for all 4 metrics), demonstrating that it performs exceptionally well in making correct predictions in our sentiment analysis task. DT follows closely behind, with 0.87 across the board, showing strong performance just slightly lower than that of XGBoost. KNN also performed well, with an F_1-score of 0.85, but LR, while decent, lagged behind with a score of 0.74 in all metrics, suggesting that it may not be a suitable choice for our sentiment analysis task. Overall, XGBoost was the clear winner in terms of accuracy and balanced performance.

Table . Results for machine learning models.

Model	Precision	Recall	F_1-score	Accuracy
Logistic regression	0.74	0.74	0.74	0.74
Decision tree	0.87	0.87	0.87	0.87
K-nearest neighbors	0.85	0.86	0.85	0.86
Extreme gradient boosting	0.92	0.92	0.92	0.92

Results for DL

In text classification tasks, choosing the right model and word embedding technique is essential for achieving accurate results. For this analysis, we compared the performance of 2 popular DL models (CNN and BiLSTM) using 2 different types of word embeddings: FastText and GloVe.

Table 5 compares the performance of different DL models using FastText and GloVe embeddings. When using FastText, CNN performs the weakest, with an F_1-score of 0.72, while BiLSTM performs significantly better at 0.91. However, models trained with GloVe embeddings outperformed those trained with FastText. The CNN model with GloVe achieved the highest performance across all metrics (0.94), followed closely by BiLSTM with 0.93. This suggests that GloVe embeddings provide richer semantic representations for this task, leading to better model performance, especially for CNN. Overall, GloVe-based models outperformed their FastText counterparts, and CNN with GloVe achieved the best results.

XSL•FO
RenderX

Table . Results for deep learning models.

Models	Precision	Recall	F_1-score	Accuracy
FastText: convolutional neural network	0.72	0.72	0.72	0.72
FastText: bidirectional long short-term memory	0.91	0.91	0.91	0.91
Global Vectors for Word Representation: convolutional neural network	0.94	0.94	0.94	0.94
Global Vectors for Word Representation: bidirectional long short-term memory	0.93	0.93	0.93	0.93

Transformer Results

Multimedia Appendix 4 presents the performance comparison of 3 transformer-based models—RoBERTa-base, crosslingual language model (XLM)–RoBERTa-base, and BERT-base-uncased—across 4 key metrics: precision, recall, F_1-score, and accuracy. The RoBERTa-base model (blue bars) consistently outperformed the others, achieving a score of 0.94 in all metrics. The XLM-RoBERTa-base model (red bars) performed equally well in recall and accuracy but lagged slightly in precision and F_1-score. Meanwhile, BERT-base-uncased (green bars) had the lowest performance, with a score of 0.93 across all metrics. Although the differences are small, they highlight how model architecture influences classification performance, with RoBERTa-based models proving to be slightly more effective in this particular task.

Overall, RoBERTa-base outperformed the other models with the highest scores across all metrics, making it the most effective for this task. Although XLM-RoBERTa-base was close, BERT-base-uncased showed slightly lower performance.

LLM Results

LLMs have revolutionized the field of artificial intelligence by enabling machines to understand and generate human-like text with remarkable accuracy. LLM models are trained on a large volume of textual data, allowing them to capture hidden patterns in language, comprehend complex queries, and produce coherent and contextually relevant responses. By using the capabilities of LLMs such as GPT-3.5 Turbo, researchers and developers can unlock innovative solutions, bridging the gap between human communication and machine intelligence. To attain this objective, we have used the power of OpenAI's model for the sentiment analysis task and we evaluated its effectiveness using 4 metrics: precision, recall, accuracy, and F_1-score. Multimedia Appendix 5 presents the performance of GPT-3.5 Turbo across the 4 key metrics, all achieving an impressive 0.95. This indicates that GPT-3.5 Turbo performs exceptionally well in classification tasks, likely benefiting from its large-scale pretraining and contextual understanding. Compared to traditional ML models or even DL architectures, its high and balanced performance across all metrics suggests strong generalization and robustness in text classification.

Overall, GPT-3.5 Turbo excelled, with a perfect balance across all metrics (0.95), making it a highly effective choice for text classification tasks.

Table 6 shows the class-wise performance metrics of our proposed methodology (GPT-3.5 Turbo) on 6 distinct classes, capturing both positive experiences (ie, pain relief, euphoria, relaxation) and negative outcomes (ie, nausea, sadness, respiratory depression), and highlights precision, recall, F_1-score, and support (number of instances per class). Among the classes, euphoria, nausea, and respiratory depression showed the highest performance, achieving nearly perfect scores across all metrics. Euphoria, relaxation, and pain relief also performed well, with slight variations in precision and recall. Sadness, however, had the lowest recall (0.85) and F_1-score (0.89), indicating that the model struggled slightly with detecting this class.

Table . Class-wise score for the GPT-3.5 Turbo model.

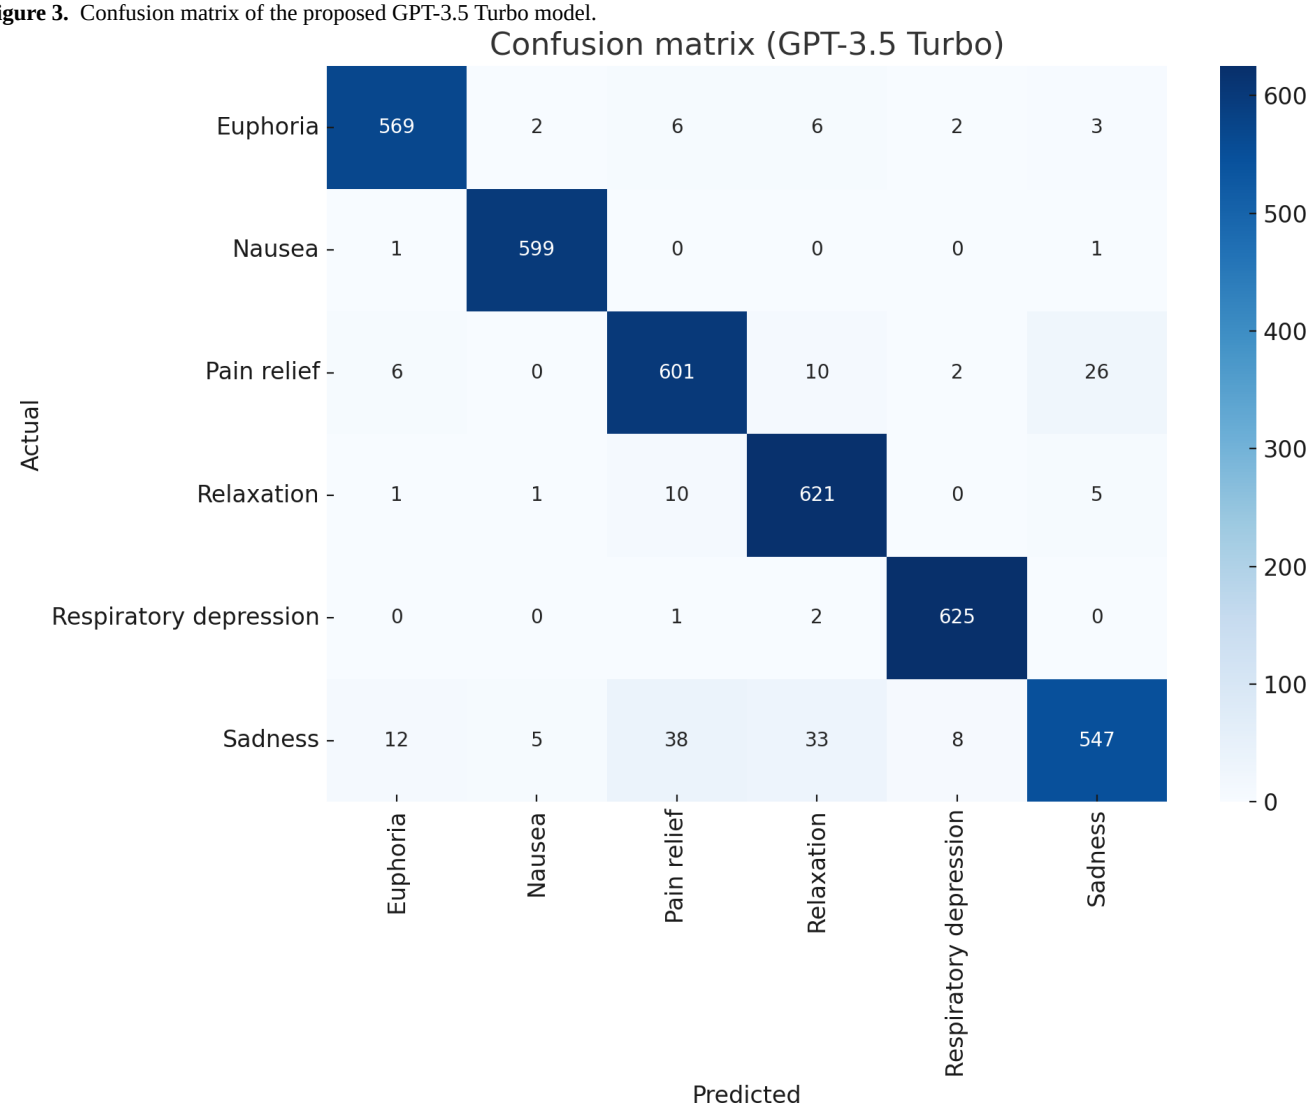
Class	Precision	Recall	F_1-score	Support
Euphoria	0.97	0.97	0.97	588
Nausea	0.99	0.99	0.99	601
Pain relief	0.92	0.93	0.92	645
Relaxation	0.92	0.97	0.95	638
Respiratory depression	0.98	1	0.99	628
Sadness	0.94	0.85	0.89	643

Overall, the model performed exceptionally well across most classes, with nausea and respiratory depression achieving

XSL•FO
RenderX

near-perfect classification. However, sadness had the lowest recall, suggesting room for improvement in detecting this category.

Error Analysis



Multimedia Appendix 6 presents the top-performing models across various learning approaches based on their precision, recall, accuracy, and F_1-score metrics. Among ML techniques, the XGBoost model excelled, with solid precision, recall, F_1-score, and accuracy values of 0.92. In DL, the CNN model with GloVe embeddings achieved 0.94 in all metrics. For transfer learning, the roBERTa-base model matched this, achieving a score of 0.94 across the board as well. Finally, GPT-3.5 Turbo (an LLM) took the lead with slightly higher performance, boasting a precision, recall, F_1-score, and accuracy of 0.95, showing its exceptional ability in handling complex tasks. Overall, each approach demonstrated strong performance, but GPT-3.5 Turbo stood out as the highest achiever.

Although RoBERTa-base achieved solid performance with an accuracy, precision, recall, and F_1-score of 0.94, GPT-3.5 Turbo outperformed it with 0.95 across all metrics. This 1.06% performance improvement shows GPT-3.5's superior ability to capture complex, nuanced language patterns and generalize better to diverse user sentiments related to opioid use. Although RoBERTa excels in domain-specific tasks, GPT-3.5 Turbo's versatility allows it to handle a wider range of emotional expressions more effectively. As the dataset size increases, GPT-3.5 Turbo's performance is expected to improve further, reinforcing its edge in predicting overdose risks and understanding nuanced user experiences.

Table 3 summarizes the learning approaches, models, and hyperparameters used across various ML and DL techniques. GPT-3.5 Turbo was fine-tuned with a learning rate of 2, 3 epochs, a batch size of 29, and seed=1,414,121,048, ensuring effective adaptation. Transformer models such as BERT, RoBERTa, and XLM-RoBERTa used a learning rate of 2e-5, 3 epochs, a batch size of 32, AdamW as the optimizer, and CrossEntropyLoss for classification tasks. ML models included KNN (n_neighbors=5, weights='uniform'), XGBoost (n_estimators=100, max_depth=6, learning_rate=0.3), DT (random_state=42, max_depth=10), and LR (random_state=42, max_iter=1000, C=0.1, solver='liblinear'). DL models like BiLSTM and CNN were trained with a learning rate of 0.1, 3 epochs, an embedding dimension of 300, and a batch size of 32. Each model's hyperparameters were fine-tuned to optimize performance for specific tasks, ensuring efficient learning and improved accuracy. Figure 3 shows the confusion matrix of the proposed model (GPT-3.5 Turbo).

Discussion

Principal Findings

This study highlights the effectiveness of sentiment analysis in extracting meaningful insights from self-reported experiences with opioid drugs mixed with illicit substances. By leveraging YouTube comments as a data source, we were able to analyze public discourse on opioid use, uncovering both positive and negative experiences. Our classification system, comprising 6 sentiment-based categories, provided a structured approach to understanding the emotional and physical effects associated with opioid consumption. Notably, this method allowed us to identify key adverse effects such as nausea, respiratory depression, and sadness, alongside reported benefits like pain relief and euphoria.

A significant contribution of this research is the application of OpenAI models such as GPT-3.5 Turbo for sentiment analysis. The model achieved an F_1-score of 0.95 in a multiclass setup, outperforming the baseline XGBoost model by 3.26%. This improvement underscores the utility of advanced NLP techniques in analyzing complex, health-related discussions. By automating the classification process, our approach reduces reliance on manual annotation and offers a scalable solution for monitoring opioid misuse trends. Such insights can enhance pharmacovigilance efforts, enabling real-time analysis of user-generated content to support public health initiatives.

Limitations

Despite its contributions, this study has several limitations. First, the reliance on YouTube as the primary data source may not fully capture the diversity of opioid-related discussions across different social media platforms. Platforms such as X, Facebook, and Reddit have distinct user demographics and language patterns, which could influence sentiment classification outcomes. Expanding data collection to multiple platforms would improve the generalizability of our findings.

Second, the manual annotation process, while aimed at ensuring accuracy, remains inherently subjective. Variability in human interpretation of comments may introduce inconsistencies in the dataset. Future studies could explore semisupervised learning techniques or crowd-sourced annotations to enhance labeling reliability.

Additionally, the 6-class sentiment framework, while comprehensive, may not capture the full spectrum of opioid-related experiences. Refining the classification system to include more granular sentiment categories could provide

XSL•FO
RenderX

deeper insights. Moreover, GPT-3.5 Turbo, despite its strong performance, exhibits occasional errors in interpreting medical terms and context-specific nuances, which may impact classification accuracy.

Conclusions and Future Work

This study demonstrates the effectiveness of ML, DL, and LLMs in analyzing public sentiment surrounding opioid use mixed with other substances. By manually annotating YouTube comments into 6 distinct sentiment-based classes—capturing both positive effects (eg, pain relief, euphoria, relaxation) and negative experiences (eg, nausea, sadness, respiratory depression)—we provided a nuanced understanding of opioid-related discussions.

Our proposed methodology, using GPT-3.5 Turbo, achieved the highest F_1-score of 0.95, outperforming traditional ML models such as XGBoost, which demonstrated an F_1-score of 0.92. This significant improvement underscores the potential of LLMs in accurately identifying high-risk opioid use patterns from user-generated content.

By leveraging social media as a real-time source of self-reported experiences, this approach offers a scalable and less invasive method for opioid surveillance. The findings highlight the potential for artificial intelligence–driven tools to enhance health care interventions and public health strategies by identifying overdose risk more accurately. Future research can expand on this work by incorporating real-time monitoring, larger datasets, and additional language models to further improve predictive performance and intervention strategies.

In future work, we will focus on several key areas. First, we will expand the dataset to include comments from multiple social media platforms, such as Reddit, X, and Facebook, which will enhance the robustness and applicability of the model. Additionally, we plan to expand our dataset to include multilingual content to capture a broader spectrum of experiences across different language groups. Incorporating demographic and geographic metadata could further refine the analysis, providing insights into regional and population-specific trends in opioid use.

Second, refining the classification system by incorporating additional sentiment categories or leveraging hierarchical classification techniques could improve the granularity of sentiment detection. Finally, integrating real-time monitoring capabilities into public health frameworks could facilitate proactive intervention strategies. By developing automated tools for detecting emerging opioid-related trends, policymakers and health care professionals could respond more swiftly to potential risks, ultimately contributing to more effective opioid crisis management.

Overall, this research underscores the potential of sentiment analysis in public health surveillance and emphasizes the need for ongoing advancements in NLP methodologies to improve opioid misuse detection and intervention strategies.

Abstract

Background: Nutritional yeast, an inactive form of *Saccharomyces cerevisiae*, has recently become increasingly popular as a food supplement and healthy ingredient, especially among individuals following plant-based diets. It is valued for its health benefits and high content of B vitamins, minerals, and protein. Social media has enabled people to share information and personal experiences at an unprecedented level, further amplifying conversations around health and nutrition. With the rise of social media, data mining techniques like natural language processing and machine learning are increasingly used for analyzing the large amounts of information generated on these platforms.

Objective: This study aimed to analyze social media data from the United States and France to identify the most frequently discussed topics among nutritional yeast consumers. The objective was to fill gaps in our understanding of the perceptions, experiences, and usage trends related to nutritional yeast.

Methods: This study was retrospective, using social media data geolocated in the United States and France, posted by users discussing nutritional yeast between December 2017 and September 2023. Data cleaning and filtering were done using natural language processing methods and specific algorithms. Biterm topic modeling was applied to identify the most frequently discussed topics.

Results: A total of 36,642 posts written by 28,069 users discussing nutritional yeast were identified across 1039 publicly available online sources. This included 34,292 posts from the United States (26,154 users across 994 sources) and 2350 from France (n=1915 users across 45 sources). Twitter was the most commonly used platform in both countries, accounting for 39.6% of posts in the United States (13,587/34,292) and 84.3% in France (1982/2350). In the United States, conversations centered around the role of nutritional yeast role as a vegan nutrient source (n=12,345, 36.0%). Several users highlighted its culinary versatility as a natural seasoning (n=8093, 23.6%) and its health and skin benefits (n=6173, 18.0%). In France, discussions frequently focused on nutritional yeast's use in dietary supplement routines in various forms (n=1177, 50.1%), emphasizing its benefits alongside other supplements such as castor oil, particularly noted for effects on nails and hair (n=928, 39.5%).

Conclusions: This social media listening study identified the perceptions and preferences of nutritional yeast users in France and the United States. Researchers and health care professionals can reflect on these findings to investigate the potential health benefits of nutritional yeast for specific groups and its long-term impact on different diets and lifestyles. Marketers may also use this information to create customized strategies that better align with the preferences and needs of each market.

(JMIR Infodemiology 2025;5:e60528) doi:10.2196/60528

KEYWORDS

nutritional yeast; social media listening; natural language processing; machine learning; infodemiology study

Introduction

For thousands of years, yeast has been used in the preparation of food and beverages due to its fermentation properties in baking and brewing. Nutritional yeast, an inactive form of *Saccharomyces cerevisiae* [1], has been consumed for its health benefits since the early 20th century. More recently, it has become popular as a food supplement and cooking ingredient. Nutritional yeast—also known as brewer's yeast—is rich in B vitamins, minerals, and protein, making it both nutritious and flavorful [2,3]. In today's world, where healthy living is a priority for many, it has become an important part of vegan and vegetarian diets. Individuals following a raw vegan diet and

XSL•FO
RenderX

experiencing B12 deficiency showed significant improvement after supplementing with nutritional yeast and sublingual B12 tablets, whereas probiotic supplements did not yield similar benefits [4]. Additionally, a randomized double-blind clinical trial involving adults with type 2 diabetes mellitus found that brewer's yeast supplementation improved blood pressure [5]. Another study reported beneficial effects on serum triacylglycerol and glucose tolerance [6]. Nutritional yeast has also been shown to support the immune and gastrointestinal systems; it includes probiotics and postbiotics that help in immune modulation, strengthening the body's defense against pathogens [7,8]. Furthermore, it contributes to the balance and growth of gut microbiota, promoting gastrointestinal health and overall well-being [9,10]. As awareness of healthy nutrition continues to grow, nutritional yeast is gaining popularity among a broader population looking for healthier food options or to modify their shopping, cooking, and eating habits as a whole [3,11].

As consumers become more health conscious and search for information about food supplements, they are increasingly turning to social media to gain knowledge about health and nutrition [12]. Users engage online for various purposes, including sharing information and personal experiences, participating in medical education [13], gaining awareness around health campaigns [14,15], and becoming members of online communities [16]. Twitter, Facebook, and health-related forums are increasingly used for information about nutrition, dietary supplements, and related topics [17-19], especially among younger individuals [20].

Given the vast volume of data generated through social media, data mining is being applied to analyze user-generated content [21]. This artificial intelligence technique includes natural language processing, which allows machines to analyze textual data to comprehend human language [22], and machine learning, which creates algorithms that recognize patterns in data and produce predictions [23], both of which are progressively used within this framework [24]. As a result, public perceptions, trends, and behaviors can be identified.

Although nutritional yeast is gaining popularity, knowledge about public opinions and usage patterns is still limited. While previous research has explored its health benefits, little is known about the discussions surrounding it, particularly on social media. Moreover, comparative analyses between different cultural and geographical contexts, such as the United States and France, are scarce. This study, which focuses on online discussions in the United States and France, aims to fill this gap by exploring how nutritional yeast is discussed, used, and perceived. Through data mining, we aim to identify the main topics of discussion on social media among consumers of nutritional yeast.

Methods

Study Design and Population

The present study is retrospective, using data from social media posts by nutritional yeast users geolocated in the United States and France.

Data Extraction

Between December 2017 and September 2023, messages were retrieved from general, publicly accessed sites (eg, Twitter, Reddit) and health-related forums (eg, Doctissimo in France and HealthUnlocked [25] in the United States). Due to restricted data access and closed groups, Facebook and WhatsApp were excluded from this study. An extraction query featuring relevant keywords was first developed to identify pertinent messages. Keywords associated with nutritional yeast were included in English (eg, brewer's yeast, nutritional yeast) and French (eg, levure de bière, *Saccharomyces cerevisiae*). The complete list of keywords was subsequently used in the extraction query (Multimedia Appendix 1).

Using the Brandwatch extractor (Cision Ltd.) [26], we identified and gathered all publicly available posts that contained one of the required keywords, along with their associated metadata (eg, author, publication date). Posts were also geolocated using Brandwatch. When applicable, various spellings of a keyword were considered in the extraction query. For example, the word bière was inserted as biere, bierre, and bier and the words brewer's yeast were included as brewer's yeast and brewer yeast. This approach allowed us to increase exhaustivity by including the various ways an internet user might spell a keyword.

Data Cleaning

First, messages were harmonized to ensure consistency across the dataset. We switched all characters in the messages to lowercase format and removed all accents and apostrophes from words; this approach helped achieve a smoother cleaning, and eliminating duplicates.

The cleaning process then established a list of exclusion criteria, removing messages from sources deemed unsafe or irrelevant (eg, advertising websites, forums related to cars, pets, or animals), duplicate posts, messages containing five words or less, and posts exceeding 10,000 characters. Generally, a message with fewer than five words does not contain enough information to be effectively exploitable and interpreted. Messages exceeding 10,000 characters are rare and nevertheless, are excluded from the analysis dataset due to excessive processing time.

To determine the number of messages for each keyword, we applied a "presence" step. This involved automatically searching the dataset for keywords and identifying the messages that contained them. Not all messages mentioning nutritional yeast were from people who had consumed it—some may have been discussing it without personal use. To address this, we applied a supervised machine learning algorithm [27] to identify messages specifically from nutritional yeast users. This algorithm classified each message by determining whether the user had taken the mentioned "treatment" (nutritional yeast), assigning a value of 0 for no intake and 1 for intake. It analyzed language to make predictions, including first-person pronouns to detect personal use, sentiment words to understand the emotional context, verb tenses for timing, negation words, and possessive pronouns to detect whether a statement denied or confirmed use. The algorithm was trained and tested on a sample

XSL•FO
RenderX

of 1563 messages that spanned a range of pathologies. Its ability to detect whether a treatment was taken generated the following performance results: accuracy, 72%; F_1-score, 74%; sensibility, 78%; specificity, 66%; and precision, 70%. To extend its application to English-language messages, we translated these into French before applying the algorithm, which was initially developed and optimized for French. We then separated the messages into French and US datasets based on the language of the original messages.

Multiple human annotators annotated random samples of messages to further validate the algorithm's output. This step ensured that the algorithm's results were pertinent and accurate.

Topics of Discussion

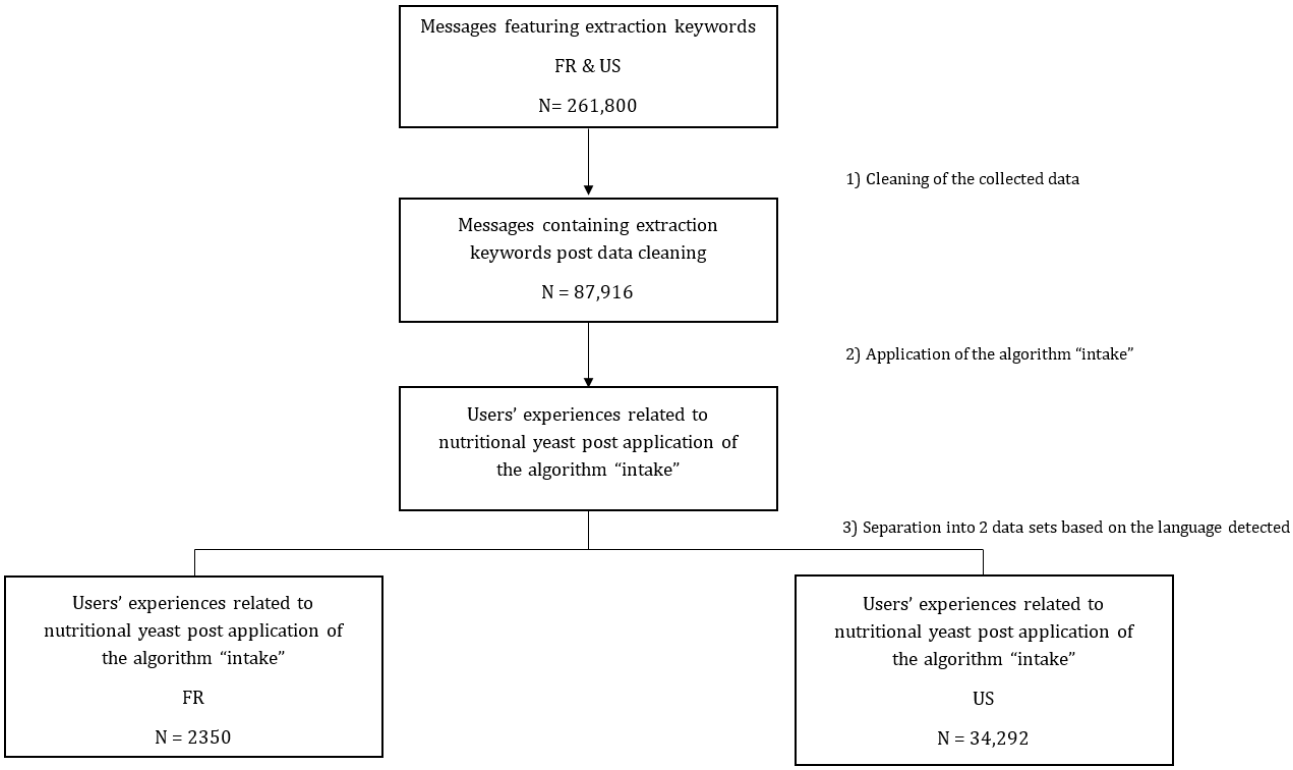
The main discussion themes among nutritional yeast consumers were identified using Biterm Topic Modeling (BTM). BTM is a natural language processing approach that analyzes large volumes of text and clusters similar text based on common topics [28]. BTM automatically groups messages into different categories—each representing a specific topic—in descending order of frequency. For each category, BTM provides a list of the most recurring words, which helps understand the general focus of each topic. For example, a BTM result about breast cancer may include:

Topic 1 | Proportion of messages = x | List of most frequently mentioned words: body, image, confidence, scars, mastectomy, hair loss, appearance, self-esteem, femininity.

These words suggest a focus on body image issues, which can be further validated when reviewing the messages associated with Topic 1. This allows us to assign a title to the topic, such as *Impact of breast cancer on body image.*

In this study, we applied BTM separately to the US and French datasets without prior knowledge of the topics. For each country, BTM generated distinct categories, providing a list of the most recurrent keywords and the messages associated with each category. Based on the list of keywords, we obtained an initial understanding of each topic. We then reviewed the messages in each category to validate and refine our understanding. This allowed us to assign appropriate titles to the topics.

Ethical Considerations



This study used only data from publicly available sources, excluding private groups, forums, and web pages. Given that users posting on public platforms automatically agree to the reuse of their information, we did not seek formal consent for this study. The findings are reported in aggregate, without personally identifiable details such as names, usernames, specific locations, or sensitive information, were deliberately removed.

Results

Population and Posts

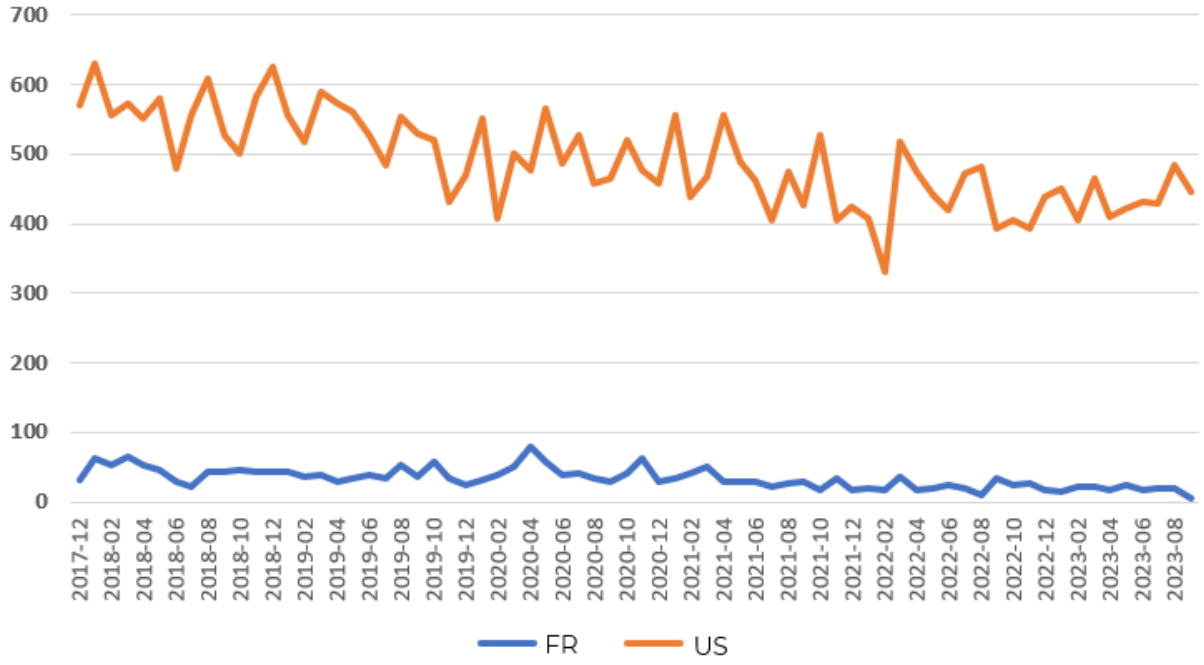
A total of 261,800 posts were initially retrieved, written by internet users discussing nutritional yeast in the United States and France. Data cleaning and processing allowed us to identify internet users who had consumed nutritional yeast. As a result, the analysis dataset contained a total of 34,292 posts in the United States written by 26,154 users and 2350 posts in France written by 1915 users (Figure 1).

Figure 1. Flowchart of the data cleaning and sample selection processes showing the number of messages (N) and users discussing nutritional yeast in the United States and France between 2017-2023.

XSL•FO
RenderX

Data Sources and Temporal Evolution

Posts originated from 995 social media platforms in the United States and 45 in France. In the United States, Twitter was the main source of data (13,587/34,292; 39.6%) of posts, followed by Reddit.com (n=5333; 15.6%), and Instagram.com (n=4398, 12.8%). In France, Twitter was also the main source of data (1,982/2,350; 84.3%), followed by jeux vidéo.com (125; 5.3%) and babycenter.fr (n=93; 4.0%) (Table 1). The complete list of sources is found in Multimedia Appendix 2.



During the analysis period, the number of posts was higher in the United States (n=34,292) than in France (n=2350). Figure 2 shows the temporal evolution of the posts extracted in United States and France.

Table . Top 10 geolocated data sources in the United States and France for messages about nutritional yeast posted between 2017-2023 .

Forum/Social media	Posts, n (%)
United States	
Twitter	13,587 (39.6)
Reddit.com	5333 (15.6)
Instagram.com	4398 (12.8)

Figure 2. Temporal trend in the number of posts on nutritional yeast extracted between December 2017 and September 2023 from social media geolocated in the United States and France.

Topics of Discussion

After applying the BTM, various discussion topics were identified through human interpretation of the most associated terms. It is worth noting that a single message can contain multiple topics. The main revealed topics are shown in Table 2.

Table . Proportions of messages featuring the most frequently discussed topics.

Topics	Posts, n (%)
United States	
Vegan vitamin source	12,345 (36.0)
Seasoning for various recipes	8093 (23.6)
Health and Skin benefits	6173 (18.0)
Taste of cheese	4218 (12.3)
Fermented products	2160 (6.3)
Protein and calorie balance	1269 (3.7%)
France	
Dietary supplement regimens in various forms	1177 (50.1)
Castor oil for nails and hair	928 (39.5)
Personal experience, diet, and taste	223 (9.5)
Reduction of hair loss, effectiveness, and duration	115 (4.9)
Yeast, a dietary supplement rich in vitamins	96 (4.1)
Organic products (purchase and diet)	31 (1.3%)

Main Topics of Discussion in the United States

The most discussed theme in the United States was nutritional yeast as a vegan vitamin source (12,345/34,292; 36.0%). Users from the vegan community mentioned it as a source of vitamins, particularly B vitamins including B12—a nutrient that is challenging to obtain from a diet lacking animal products. Users also shared their experiences of how to incorporate nutritional yeast into their daily lives, such as sprinkling it on meals or blending it into smoothies. An example message reads:

Yesterday's lunch was a salty (and spicy ... Def went too far on the red bell pepper) and hit the spot! Nutritional yeast may sound a bit odd, but it's a great source of B vitamins for eaters (translation to French in Multimedia Appendix 3)

XSL•FO
RenderX

Additionally, online discussions revealed that cooking enthusiasts have used nutritional yeast as a natural and nutritious seasoning (n=8093; 23.6%). Users posted their recipes using it as a flavor enhancer in pasta and casseroles, sharing that it added taste and creaminess without the need for dairy products. For example:

I bought a big carton of egg whites, what I did with the tofu scrabble was to add nutritional yeast, turmeric for color and black pepper, which makes it taste whole and with whole egg and egg white too. (translation to French in Multimedia Appendix 3*)*

Users frequently mentioned the health and skin benefits of nutritional yeast (n=6173; 18.0%) messages, with users highlighting its positive effects on skin health, particularly in managing fungal infections. They also discussed its ability to strengthen nails and improve hair health.

Nutritional yeast was also used as a cheese alternative (n=4218 messages; 12.3%). It was especially popular among vegans and individuals with lactose-intolerant, who praised it as a nutritious, plant-based option that can add flavor to dairy-free diets. Several users described it as both palatable and versatile, therefore important to include in one's balanced diet.

Another topic of discussion was the use of nutritional yeast in home fermentation processes (n=2160; 6.3% messages) such as brewing beer, making bread, and other fermented products. However, since nutritional yeast is an inactive form of *Saccharomyces cerevisiae*, it lacks the enzymes required for fermentation. This means that the conversations discussing fermentation have mistakenly mentioned the use of nutritional yeast.

The high protein content and low-calorie count also made nutritional yeast appealing within fitness and wellness communities (n=1269; 3.7%) messages. Users noted its importance as a complete protein, ie, containing all nine essential amino acids, which is beneficial for muscle development and maintenance.

Main Topics of Discussion in France

In France, internet users primarily discussed the use of nutritional yeast in food supplement routines (1177/2350; 50.1%). Users mentioned how they included brewer's yeast into their routines, sharing the different ways they consumed it in the form of capsules or pills. They reported using it for overall health or for specific concerns like hair loss and mood improvement. One user described their experience with brewer's yeast in the following message:

Personally, brewer's yeast worked really well, no side effects, I also tried Oenobiol, which wasn't bad, and now I'm starting Forcapil, apparently it's a wonder. I can't wait to have Rapunzel's hair (*translated from French, in Multimedia Appendix 3*).

Another frequently discussed topic was the use of castor oil for improving nail and hair health (n=928; 39.5%). Many users paired castor oil with brewer's yeast, highlighting their combined benefits in strengthening and stimulating the growth of hair and nails. Users also shared specific routines, such as applying castor oil directly to their hair or nails and taking brewer's yeast tablets as supplements. An example of a message is shown below:

I used to lose handfuls of them too, that's why they're so damaged, you need to make frequent oil masks that you leave on overnight, rinse them with cold water and take brewer's yeast to strengthen them ☺ (*translated from French, in Multimedia Appendix 3*).

Discussions also focused on personal experience, diet, and sensory attributes of brewer's yeast (n=223; 9.5%). Some users described its texture and taste, while others shared their recipes and methods for incorporating brewer's yeast into their diets. Feedback regarding its taste was generally positive, as shown in the following message:

No problem with taking care of oneself with all kinds of oils (jojoba, coconut, castor) natural shampoo like Liperol, and brewer's yeast in capsules and powder form (I like the taste) (*translated from French, in Multimedia Appendix 3*).

Other messages revolved around the effect of nutritional yeast in reducing hair loss (n=115; 4.9%), as well as its role as a food supplement rich in vitamins (n=96; 4.1%), particularly the B complex. Although less commonly discussed, some users expressed a preference for organic products (n=31; 1.3%), specifically organic brewer's yeast.

Discussion

Principal Findings

The objective of the study was to identify the predominant themes in conversations among internet users discussing nutritional yeast.

A total of 36,642 messages posted by 28,069 users were included in this study. Twitter emerged as the main source of discussion in both countries, accounting for 39.6% of the US dataset with 13,487 posts and 84.3% of the French dataset with 1982 posts. Additional key platforms included Reddit and Instagram in the United States, and jeux vidéo.com and babycenter.fr in France. In the US, discussions mainly focused on its role as a nutrient source for individuals following a vegan diet (36.0% of posts). Many users reported using it as a natural seasoning (23.6%) and for its benefits for health and skin (18.0%). Users also discussed cheese alternatives (12.3%), specifically using nutritional yeast as a substitute for cheese. In France, nutritional yeast was part of supplement regimens in various forms (50.1% of posts) and was used with other supplements such as castor oil, mainly to improve nail and hair health (39.5%). Additional themes included personal experiences regarding dietary habits and flavor preferences (9.5%), the role of nutritional yeast in preventing hair loss (4.9%), and its high vitamin content (4.1%).

Our findings are consistent with previous studies highlighting the role of plant-based foods in today's diets. In the United States, nutritional yeast was already recognized as an important component in vegan nutrition, with a rapid transition to plant-based diets. In fact, veganism in the United States increased by 600% between 2014 and 2018 [29], motivated by

XSL•FO
RenderX

health concerns, environmental sustainability, ethical considerations regarding animal welfare, and media influence [29-31]. Additionally, the plant-based foods market increased by 29% from 2017 to 2019 [32], highlighting the rising demand for plant-based foods among American consumers [33].

Conversely, nutritional yeast was mostly considered a dietary supplement in France, which is consistent with the French tendency to favor holistic health solutions. According to data from the Second Individual and National Study on Food Consumption (INCA), 22% of French adults consume dietary supplements on a regular basis [34], especially women, individuals aged 18 to 44, and those with higher education levels [34]. Although most adults still buy supplements from pharmacies, online purchases have significantly increased from 1% in 2015 to 11% in 2019—a clear shift in consumer habits [34]. In 2022, more than two-thirds of the French population had used dietary supplements at least once, with 32% reporting use in the past three months [35]. The market for nutritional supplements has grown to €2.6 billion and had a+3% yearly growth rate between 2021 and 2022 [36].

Our results align with previous research emphasizing the value of social media in understanding health and nutrition. With the help of data mining, social media has become a powerful source of real-world data, providing insights that traditional research methods such as clinical trials may fail to obtain. It also bypasses some of the limitations of conventional research such as lengthy timelines and complicated participant recruitment processes, making it a useful complementary tool for health research [37-39]. Infodemiological studies allow for the identification of various aspects, including specific populations, their discussion topics, the impact of health on their quality of life, as well as user perceptions and challenges [40-43]. They offer significant data, with 5.35 billion internet users and 5.04 billion actively using social media platforms in 2024 [44]. Consistent with our findings, previous studies have also identified Twitter as an essential source of data and a valuable platform for health-related discussions [38,45-48].

This study may help shape marketing strategies for each country's unique preferences. In France, where consumers were focused on improving their overall health and well-being, marketing strategies could emphasize the holistic benefits of nutritional yeast—perhaps including it as part of multisupplement regimens. In the United States, the growing population of health-conscious, plant-based consumers presents an opportunity to focus on nutritional yeast's role in vegan diets and its versatility in cooking, particularly as a natural flavor enhancer. Strategies could include creating educational content, collaborating with culinary experts, and launching targeted social media campaigns to effectively promote nutritional yeast's benefits in both regions.

Limitations

We recognize several limitations to our study. Our analysis only included openly accessible online sources; private sources such as WhatsApp, private forums, or invitation-only groups were excluded. Furthermore, the level of detail that we obtained and our understanding of the messages' context depended on the information shared by users. Our study included a potential recall bias, as it was based on users' self-reported data, their memory, and subjective interpretation. Additionally, individuals posting on social media may represent certain socioeconomic backgrounds and literacy capacities, which could affect the representativeness of our findings. It is also possible that relevant discussions were incorrectly removed during data cleaning. Another limitation is the variation in the number of users from each country, which may affect data representation. Additionally, since not all social media posts include geolocation data, accurately determining their country of origin can be challenging.

Despite these limitations, this study provides valuable insights into the discussions and perceptions about nutritional yeast.

Conclusions

Nutritional yeast is a natural ingredient valued for its health benefits and culinary versatility by users in France and the United States. Social media allowed us to gain insights into consumer perspectives, experiences, and usage trends related to nutritional yeast. It also allowed the identification of the unique preferences of each country, providing more information about the health-focused French consumers and the growing American vegan population. Future research could include clinical studies to better understand the health benefits of nutritional yeast for specific groups, such as vegans or people interested in natural beauty solutions. Studies could also explore its long-term effects on various diets and wellness habits. Additionally, marketing strategies could be improved by creating tailored communication and messaging that connect more effectively with the preferences and needs of various consumer groups.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to the proprietary nature of the algorithms and data used, which are the intellectual property of Kap Code, and in order to comply with the General Data Protection Regulation (Regulation [EU] 2016/679).

Abstract

Background: Vulvodynia is a chronic vulvar pain condition affecting up to 25% of the US population. However, diagnosis and effective treatment remain elusive. Many individuals with vulvodynia face stigma and medical uncertainty, leading them to seek information and web-based support. Reddit is a popular social media platform where patients share health concerns and experiences. The anonymity and accessibility of this platform make it a valuable source of real-world patient perspectives that are often overlooked in clinical settings.

Objective: This study evaluated Reddit content related to vulvodynia to explore how individuals with vulvodynia describe their symptoms, treatments, and personal experiences.

Methods: The subreddits “r/vulvodynia” and “r/vestibulodynia” were selected for analysis in May 2023. Threads were sorted from the most popular to least popular, with “popularity” measured by upvotes. Opening threads from the top 70 posts in each subreddit were extracted and analyzed using inductive qualitative analysis to identify themes and sentiment analysis to evaluate attitudes.

Results: In May 2023, the “r/vulvodynia” and “r/vestibulodynia” subreddits had a total of 7930 members (7245 and 685 members, respectively). Out of 140 analyzed threads, 77 (55%) contained negative attitudes. A total of 50 (35.7%) threads were seeking information or advice and 90 (64.3%) included some form of peer support. Inductive thematic analysis identified 6 core themes: symptoms (n=86, 61.4%), treatments (n=83, 59.3%), sexuality (n=47, 33.6%), erasure or disbelief (n=38, 27.1%), representation or media (n=17, 12.1%), and humor (n=15, 10.7%). Threads that discussed treatments (48/83, 57.8%), sexual experiences (25/47, 53.2%), and representation (14/17, 82.4%) had the highest proportions of positive attitudes, while threads that touched on erasure (21/38, 55.3%), symptoms (51/86, 59.3%), and humor (12/15, 80%), had the highest proportion of negative attitudes. A multivariable logistic regression of valence on the themes revealed that posts referring to treatments (odds ratio 12.5, 95% CI 3.7-42.2; P<.001) or representation (odds ratio 21.2, 95% CI 4.2-106.0; P<.001) were associated with significantly increased odds of positive valence. Furthermore, it was noted that 3 of the 5 most frequently discussed treatments aligned with clinical guidelines from the American College of Obstetricians and Gynecologists, American Urological Association, and International Society for the Study of Vulvovaginal Disease. Despite this alignment, threads frequently mentioned alternative remedies and frustration with medical professionals related to diagnostic delays and perceived lack of understanding.

Conclusions: This is the first study of Reddit discussions about vulvodynia. Findings suggest a gap between patient experiences and provider understanding, underscoring the need for improved patient education and greater clinician awareness of psychosocial factors in vulvodynia care. While limited by its sample size and lack of demographic data, this study highlights how web-based communities can help identify ways health care providers can better meet patient needs and how patients mutually support each other.

KEYWORDS

sexual health; health literacy; vulvodynia; vestibulodynia; pelvic pain; Reddit

Introduction

Vulvodynia is defined as vulvar pain lasting for at least 3 months without an identifiable cause. Vulvodynia is characterized by the location of pain (eg, localized or generalized), triggers (provoked, spontaneous, or mixed), onset (eg, primary or secondary), and temporal nature (eg, intermittent, constant, or delayed) [1,2]. The most common subtype of vulvodynia is vestibulodynia, which is pain isolated to the vulvar vestibule [2].

Vulvodynia is prevalent, affecting up to 1 in 4 women in the United States [3,4]. However, the majority of people living with vulvar pain remain undiagnosed and inadequately treated. It is reported that nearly 40% of people with chronic vulvar pain do not seek treatment, and of those that do, 60% consult at least 3 physicians before receiving a diagnosis, if they receive one at all [3]. Factors contributing to this gap in care may include a lack of knowledge on the part of medical providers, inadequate medical education related to vulvar anatomy and physiology, longstanding dismissal of female pain, and stigma surrounding female reproductive organs and sexuality [5-7].

Since the advent of the internet, individuals have sought web-based medical information, often before consulting health care professionals [8,9]. For individuals with understudied health conditions, digital health forums can be essential sources of information and peer support [10]. Moreover, web-based platforms may allow individuals with chronic diseases to connect with one another and build a social identity that extends beyond the disease itself [11].

Reddit, a popular website with 1.5 billion registered users and over 52 million daily users is a notable platform for exchange and anonymized information-sharing [12]. By design, Reddit facilitates open discussion across various topics, allowing for global information exchange that is not as readily facilitated on other platforms such as Instagram or Facebook. Reddit is organized into various subreddits, which are discussion-based communities devoted to an identified topic or theme. Within a typical subreddit, a user makes a post expressing an opinion or sharing information. Other users can evaluate that post by "upvoting" or "downvoting" it. Users can reply to the initial post or others who have replied to the post. Together, the post and subsequent comments are known as a "thread."

The anonymous nature of Reddit may be beneficial because it lends itself to open and often vulnerable exchanges. Prior studies have explored Reddit content related to substance use, chronic pain, sexual dysfunction, and mental health, providing key insights into the lived experiences of those who may feel shame [13-17]. Despite relatively extensive investigation of these topics with varied analytic techniques, there is little research on Reddit content related to female sexual dysfunction. Existing studies primarily focus on reproductive conditions, changes in libido, or abortion [18-22]. To date, there has been no study examining how Reddit may be used by patients to obtain or share information about vulvodynia.

While population-level data on patient experiences of vulvodynia exists, patient-centered studies that capture the experiences of individuals living with vulvodynia are rare [23-25]. This study therefore seeks to qualitatively assess patient experiences of vulvodynia as discussed on Reddit, amplifying person-centered perspectives and gauging gaps in medical care for those affected by vulvodynia. By capturing these narratives, this study highlights the importance of understanding patient experiences beyond the clinical setting, which can inform more empathetic and effective health care strategies.

Methods

Subreddit Selection

To evaluate Reddit forum content related to vulvodynia, this study used a cross-sectional design, analyzing publicly available data from "r/vulvodynia" and "r/vestibulodynia," in May 2023 [26,27]. The "r/vestibulodynia" subreddit was included to provide a more comprehensive understanding of patient experiences, as vestibulodynia is a specific form of vulvodynia.

For each subreddit, threads were sorted from the most popular to the least popular. A thread becomes popular based on the number of upvotes, comments, and overall engagement it receives from others in the Reddit community. We collected and analyzed the most popular 70 threads from each subreddit, as they were deemed most representative of key topics in the community. Comments from other users on each thread were excluded from the analysis.

Thematic and Sentiment Analysis

Quantitative and qualitative data, including the number of upvotes and comments, the post title, and a brief description of the post, were collected by accessing the Reddit website directly and navigating subreddits directly through the site. Data were collected using Google Chrome (version 113) and Safari (version 16.5) web browsers under default settings (cache and cookies enabled, no use of privacy or incognito mode) to simulate a typical user experience. The data were directly downloaded and preserved in an Excel (version 16.82; Microsoft Corp) spreadsheet on May 7, 2023, at approximately 6 PM EST. Four team members (SP, EM, KS, and AP), located in New York, Ventura, Memphis, and Glen Head, served as coders. Extracted data were coded between May 7, 2023, and May 15, 2023. These coders independently assessed all 140 threads, using a thematic analysis approach. All posts were manually annotated, and the themes were derived through iterative review and comparison. Codes were revised as necessary based on commonly identified themes, following established qualitative analysis procedures and an inductive approach in which the analysis is guided by the data itself, allowing for themes to emerge organically [28-30]. Each thread was assigned 1 or multiple themes. Threads were also evaluated for tonal expression. We defined "positive" attitudes to be any expression of optimism, relief, or joy, as well as references to "cures," and observational or light humor. "Negative" attitudes were defined

XSL•FO
RenderX

as any expression of frustration, despair, fear, or isolation, as well as mentions of pain, pessimism, exhaustion, or unresolved symptoms, and dark humor with elements of bitterness or the macabre or morbid.

Any discrepancies in themes and attitudes based on individual coding were identified by AJG who was not involved in coding. All instances of coding discrepancy were resolved by group consensus, a practice used in qualitative research to constructively arrive at a consistent understanding of the data [31,32]. For example, in cases where coding defined the post as negative because of a user's description of vulvodynia as "terrible," but also noted that the post was "positive" because it used "humor" together, the coding team engaged in a discussion of whether the post should be coded as "negative" due to the word "terrible," or as "positive" because the presence of humor suggested a more complex emotional response, such as a coping mechanism. Examples of representative threads by theme and valence are provided in Multimedia Appendix 1.

A multivariable logistic regression of valence on the 6 identified themes was conducted using STATA/BE (version 18.0; StataCorp LLC). Each post was assigned a binary code for positive or negative valence and the presence or absence of a particular theme. A 2-sided significance level was defined at α=.05.

Any mention of treatments in the subreddit was recorded and compared with guidelines from the American College of Obstetricians and Gynecologists (ACOG), American Urological Association (AUA), and International Society for the Study of Vulvovaginal Disease (ISSVD), as they are viewed as the primary sources of information about managing vulvar pain.

Ethical Considerations

The study was deemed exempt by the Institutional Review Board of the University of California San Diego and Johns Hopkins Institutional Review Board due to its observational nature and analysis of public web-based content. The original data were collected in compliance with Reddit's public content policy, which informs users that researchers can access Reddit's public content for research purposes. All Reddit usernames and any potentially identifiable information were deidentified to protect user privacy. Furthermore, no direct user interactions or private messages were included in the analysis. Only publicly accessible forum posts were analyzed, and efforts were made to ensure that the data could not be traced back to individual users through reverse searchability. In consideration of the potential ethical concerns related to social media–based research, the authors acknowledge the need to engage in ongoing academic debates regarding internet research ethics. While Reddit users agree to the public visibility of their posts, the authors recognize that these ethical discussions, such as those put forth by the Association of Internet Researchers, underscore the need to balance public data use with user privacy in research contexts.

Results

At the time of analysis, the "r/vulvodynia" and "r/vestibulodynia" subreddits had a combined total of 7930 members (7245 and 685 members, respectively). A total of 140 posts were analyzed; these posts received an aggregate of 4166 upvotes. Out of all 140 analyzed threads, 50 (35.7%) were deemed to be seeking information or advice and 90 (64.3%) were deemed to involve peer support discussions of personal experiences related to vulvodynia.

Six core themes emerged from the qualitative analysis: (1) Reddit users' subjective sense of being disbelieved about symptoms or erasure more generally; (2) difficulty managing symptoms; (3) the condition's impact on sexuality and sexual experiences; (4) representation or media; (5) humor as a coping technique or a response to the condition; and (6) treatments sought or tried.

Out of the 140 threads, the most frequently observed themes were symptoms (n=86, 61.4%) and treatments (n=83, 59.3%), followed by sexuality (n=47, 33.6%), erasure or disbelief (n=38, 27.1%), representation or media (n=17, 12.1%), and humor (n=15, 10.7%). Of all 140 analyzed threads, 45% (n=63) of threads were coded as reflecting positive attitudes, and 55% (n=77) of threads were coded as reflecting negative attitudes. The core themes of treatments (48/83, 57.8%), sexual experiences (25/47, 53.2%), and representation (14/17, 82.4%) had the highest proportions of positive attitudes in analyzed threads. The themes of humor (12/15, 80%), erasure or disbelief (21/38, 55.3%), and symptoms (51/86, 59.3%) had the highest proportions of negative attitude threads. Fleiss κ for coded valence was 0.54. The distribution of positive and negative attitudes across themes is illustrated in Table 1.

Results from the multivariable logistic regression revealed that only treatments (odds ratio [OR] 12.5, 95% CI 3.7-42.2; P<.001) and representation (OR 21.2, 95% CI 4.2-106.0; P<.001) were associated with significantly increased odds of positive valence. Nonsignificant associations were found for themes erasure (OR 1.25, 95% CI 0.5-3.0; P=.60), symptoms (OR 0.47, 95% CI 0.2-1.2; P=.11), and sexuality (OR 2.2, 95% CI 0.9-5.1; P=.07).

There were 119 instances of treatment discussions across the 140 analyzed threads. The most commonly mentioned treatments included topical medications (n=22, 18.5%), physical therapy (n=22, 18.5%), surgery (n=16, 13.4%), dilators (n=14, 11.8%), and stopping oral contraceptive pills (n=11, 9.2%). Three of the 5 most discussed treatments—physical therapy, topical medications, and surgery—aligned with clinical guidelines from ACOG, AUA, and ISSVD.

Table . Positive and negative attitudes by theme.

Theme	Positive	Negative	Total
Erasure or disbelief	17	21	38
Symptoms	35	51	86
Treatments	48	35	83
Sexuality	25	22	47
Representation or media	14	3	17
Humor	3	12	15

Discussion

Principal Findings

This is the first study to analyze Reddit posts about vulvodynia. On Reddit, individuals with vulvodynia shared personal experiences, provided advice, and found communal support. From the qualitative and sentiment analyses, 6 core themes with unique valence distributions were identified, providing insight into the experiences, priorities, and needs of individuals living with vulvodynia.

Reflections on Erasure and Being Disbelieved

A published study exploring the experience of women with vulvodynia in the United Kingdom found that health care professionals often dismiss patients' expressions of concern or physicians lack knowledge about the condition [33]. The substantial percentage of posts mentioning not being taken seriously by a health care provider, which was coded as "erasure and disbelief" indicates health care's inadequate support for patients with vulvodynia, which may explain the prevalence of negative attitude posts. Discussions of erasure and being disbelieved were present in many of the opening threads, and many users described needing to increase self-advocacy in medical settings. Such reports highlight the persistent marginalization and sense of being disbelieved during health care interactions, thereby necessitating substantial self-advocacy. Reddit users shared their disappointment with providers' behavior, attitudes, and expertise: one user shared that her doctor bluntly asked if the patient had tried lubricant, revealing a gap in understanding and empathy about vulvodynia's etiology and treatment. In aggregate, the prevalence of posts mentioning erasure and being disbelieved underscores the critical need for improved medical education and patient-centered care, 2 weaknesses of health care professionals at all levels of training [5,6,34-36].

Physical Symptoms and the Impact on Daily Functioning

Symptoms were the most prevalent theme, and many posts emphasized the wide-ranging impact of symptoms on overall health. Symptom-related posts predominantly had a negative attitude, reflecting the disruptive nature of physical discomfort in all facets of daily life. It is essential to acknowledge, however, that participants posting in these threads may not all have a formal diagnosis of vulvodynia. It is impossible to verify the truth of the contents of any of the posts. Despite this limitation, however, there were notable parallels in the dataset between user-reported symptoms and clinical diagnostic criteria for vulvodynia. Currently, there is no exclusive classification for vulvodynia; rather, a diagnosis is characterized by the description of pain [1,2,16].

Pain was the most discussed symptom, underscoring the debilitating and all-consuming nature of vulvar pain [37]. Reddit users described experiences of burning pain, pain with tampon insertion, pain during sexual intercourse, and irritation from clothing. Some symptoms mentioned, such as swollen tissue associated with tampon insertion, pain with urination, and pelvic floor tightness, do not align with established diagnostic criteria, suggesting current diagnostic tools may not capture the full range of experiences of individuals living with vulvodynia [2].

Vulvodynia can interfere with day-to-day functioning; one user noted vulvar pain made it difficult to ride a bike. Others found it challenging to stay active due to pain. Difficulties related to vulvodynia extended beyond physical discomfort; one user described how finding comfortable and wearable underwear became an unexpected source of financial stress. The heterogeneity of pain associated with vulvodynia suggests that further research is needed to better understand its etiology and develop more effective treatment strategies.

In addition to pain, the subreddit posts included expressions of anger, frustration, anxiety, depression, and even trauma, highlighting the connection between mental health and chronic pain. Although few studies have investigated mental health outcomes in individuals with vulvodynia, current evidence suggests that vulvodynia symptoms contribute to worse quality of life and many individuals living with vulvodynia have comorbid anxiety or depression [38-40]. While further research is needed, comprehensive care for vulvodynia should consider both physical and mental health to improve patient well-being.

Treatment Approaches: Navigating Options and Uncertainty

Treatment-related discussions highlight the range of difficulties individuals face in managing chronic health conditions. Participants exchanged information about various treatment modalities, sharing insights into effectiveness, side effects, and accessibility. Of posts discussing treatments, the higher proportion of positive opening threads suggests that individuals in this Reddit community often shared experiences of treatment that were effective. Three of the 5 most mentioned treatments in the Reddit threads—physical therapy, topical medications, and surgery—aligned with guidelines from ACOG, AUA, and ISSVD. To be sure, not all discussions of these treatments were

XSL•FO
RenderX

positive. However, these discussions indicate that users in this web-based forum are aware of and discuss clinically recommended treatments.

Physical therapy and vaginal creams were the top 2 treatment modalities discussed. While physical therapy is widely recognized as an effective approach for vulvodynia, vaginal creams such as baclofen and amitriptyline, though effective, are still considered novel remedies [41-43]. Surgery and discontinuing oral contraceptives were also commonly discussed. Surgery is considered for cases where conservative methods fail [1,44]. Procedures such as vestibulectomy or neuromodulation aim to alleviate pain by removing affected tissue or modifying nerve signals. Although controversial, the AUA and ACOG recommend discontinuing hormonal contraceptive treatments, as these may worsen symptoms. The literature on this topic is divided, however. Some researchers argue that long-term oral contraceptive pills may contribute to vestibulitis, while others provide evidence that refutes this connection [45,46].

Another notable challenge discussed by Reddit users is the wide variation in rates of treatment success, an observation that is well-documented in the literature [2,3,37]. Success rates for medical interventions are reported to range from 13% to 67% [47]. Note that the AUA, ACOG, and ISSVD provide slightly differing guidelines for treating vulvar pain. This may complicate care for providers already navigating serious time constraints in health care. In light of Reddit users' self-reported challenges in obtaining successful treatment for vulvodynia, harmonizing treatment guidelines would likely benefit clinicians and patients alike.

Sexuality and Relationships: Coping With Intimacy Challenges

It is not surprising that sexual experiences also emerged as a prevalent theme in these subreddit threads, given that vulvodynia directly affects individuals' intimate lives and sexual health [48]. One user shared that vulvar pain complicated their interest in sexual intimacy, demonstrating how the connection between experiences of pain, desire, pleasure, and sexual experiences may be altered by vulvodynia. Some users detailed the frustrations and challenges of finding an understanding partner, while others shared success stories of supportive and accommodating partners. Further research is needed to understand how vulvodynia impacts relationships and sexuality. In subsequent studies, qualitative interviewing would be one way to center the voices of individuals with vulvodynia.

Media Representation and Visibility

The low percentage of posts discussing representation and media highlights the invisibility of vulvodynia to the public. The prevalence of positivity in such posts underscores the urgent need for increased awareness, which can be transformative for an individual's sense of self and confidence. One user shared that representation in media made them feel less isolated in their experience. In this way, media may represent an unexpectedly positive domain in which individuals with vulvodynia can find support and recognition of their experience. Health care providers should be aware of the power of representation to positively impact individuals with vulvodynia who may feel overlooked by the medical system. For others, media can be a reminder of the difficulties associated with pain, sexuality, and daily functioning. Overall, representation was associated with significantly increased odds of positive valence, illustrating the value and importance of representation for individuals with vulvodynia.

Humor as a Coping Strategy

Humor is well-recognized as an adaptive tool for coping with stressful situations. For individuals with chronic pain, in particular, humor has been shown to reduce pain intensity and improve quality of life [49]. Explicit humor therapy, in which individuals engage with materials they find entertaining, is associated with decreased pain and feelings of loneliness [50]. In this way, humor represents a nonpharmacological approach for addressing and even ameliorating pain. Humorous interpersonal interactions have also been noted as a way for individuals with chronic pain to engage with one another and even improve clinical outcomes [51]. Members of the vulvodynia community on Reddit creatively reframed their experiences through memes and conversational threads. Users generated memes and made jokes about symptoms and interactions with doctors; in this way, the separation of body and mind may be a method of relief. Humor therefore represents a unique approach for managing experiences of vulvodynia, and it is one means by which members of the Reddit community express themselves and connect with others.

Limitations

A notable limitation of this study is the lack of access to user demographics due to the anonymous nature of Reddit. As a result, we were unable to interpret the possible effects of factors including race, age, health literacy, socioeconomic status, location, transportation, and access to health care which may have impacted the experiences mentioned by each user. Although we cannot determine whether any user had an official diagnosis or indeed met diagnostic criteria for vulvodynia, the Reddit contributors were driven to the platform for specific reasons. Furthermore, as a cross-sectional study, these results are only representative of the time in which data were collected. Results are not generalizable and should be understood as a snapshot of what anonymous Reddit users reported about vulvodynia.

Conclusions

This study aimed to better understand patient experiences of vulvodynia by analyzing web-based discussions on Reddit. Findings highlight that Reddit serves as a vital platform for sharing personal experiences, accessing peer-to-peer support, and seeking health care–related information. These web-based discussions provide valuable anecdotal evidence underscoring a need for health care providers to be trained on the management of vulvodynia, guided by consensus from professional associations. Such training would help ensure patients receive accurate diagnoses and effective care. By prioritizing and centering the patient perspective, health care providers can gain a deeper understanding of the multifaceted challenges faced by individuals living with vulvodynia. This study contributes to

XSL•FO
RenderX

existing literature by offering insights directly from those affected by vulvodynia or who are experiencing vulvodynia-like symptoms.

Abstract

Background: Patients with cancer increasingly use the internet to seek health information. However, thus far, research treats web-based health information seeking (WHIS) behavior in a rather dichotomous manner (ie, approaching or avoiding) and fails to capture the dynamic nature and evolving motivations that patients experience when engaging in WHIS throughout their disease trajectory. Insights can be used to support effective patient-provider communication about WHIS and can lead to better designed web-based health platforms.

Objective: This study explored patterns of motivations and emotions behind the web-based information seeking of patients with cancer at various stages of their disease trajectory, as well as the cognitive and emotional responses evoked by WHIS via a scenario-based, think-aloud approach.

Methods: In total, 15 analog patients were recruited, representing patients with cancer, survivors, and informal caregivers. Imagining themselves in 3 scenarios—prediagnosis phase (5/15, 33%), treatment phase (5/15, 33%), and survivor phase (5/15, 33%)—patients were asked to search for web-based health information while being prompted to verbalize their thoughts. In total, 2 researchers independently coded the sessions, categorizing the codes into broader themes to comprehend analog patients' experiences during WHIS.

Results: Overarching motives for WHIS included reducing uncertainty, seeking reassurance, and gaining empowerment. At the beginning of the disease trajectory, patients mainly showed cognitive needs, whereas this shifted more toward affective needs in the subsequent disease stages. Analog patients' WHIS approaches varied from exploratory to focused or a combination of both. They adapted their search strategy when faced with challenging cognitive or emotional content. WHIS triggered diverse emotions, fluctuating throughout the search. Complex, confrontational, and unexpected information mainly induced negative emotions.

Conclusions: This study provides valuable insights into the motivations of patients with cancer underlying WHIS and the emotions experienced at various stages of the disease trajectory. Understanding patients' search patterns is pivotal in optimizing

XSL•FO

web-based health platforms to cater to specific needs. In addition, these findings can guide clinicians in accommodating patients' specific needs and directing patients toward reliable sources of web-based health information.

Introduction

Background

Patients with cancer increasingly use web-based platforms to seek information about their diagnosis, treatment, and implications thereof in the short and long term. In the Netherlands, 85% of patients with cancer use the internet [1,2], a rate comparable to that in most Asian countries [3] and other European countries [4,5]. The internet offers a wealth of information that can be readily accessed. It provides practically limitless opportunities for finding health information and support from both lay and expert perspectives, making it a highly popular source of information for many patients.

Within the context of cancer, patients' web-based health information seeking (WHIS) behaviors have been explained through theories of coping behavior. Most often, cancer literature on information-seeking patterns revolves around coping behaviors such as monitoring and blunting. Studies suggest that most patients manage health threats by proactively seeking information, a behavior referred to as monitoring coping style, whereas others choose to avoid information and opt for distraction, known as blunting coping style [6,7]. However, some studies indicate that the WHIS behaviors of patients with cancer could be explained via a broader range of approaches than merely through theories of coping behavior [8-10]. For instance, patients with cancer could also differ in their choices regarding the kind, quantity, and origins of the sought information, as well as the strategies used for information management. These approaches are based on patients' perceptions of self-care, which means that patients vary in their WHIS based on what they need to adequately take care of themselves [10]. In addition, the reasons behind seeking information and emotional support on the web are contingent on how patients use the internet [9].

Another factor that could explain variations in how people use the internet is patients' disease and treatment stage—which may predict different needs concerning the type and amount of information [11,12]. However, studies investigating WHIS and particularly the motives to engage in WHIS often treat the behavior as a one-time event. By treating WHIS as a one-time event, researchers tend to overlook the dynamic nature of health information needs and fail to capture the evolving motivations that patients experience throughout their disease trajectory. Considering that searching for health information is a rather longitudinal behavior, especially for patients moving through different stages of the disease trajectory, a longitudinal lens is required when studying WHIS [11].

In addition to the different phases in the disease trajectory influencing how patients use the internet, WHIS may also vary depending on patients' *motives* for going on the web. For example, patients may do so to address their cognitive (ie, the need for understanding) and affective (ie, the need to be understood) needs [13]. Cognitive needs (eg, engaging with the internet to enhance preparedness and comprehension of the information provided during a consultation or to validate or challenge the information offered by the provider) will lead to diverse forms of WHIS compared to affective needs (eg, using the internet for peer interaction). In other words, patients' specific goals regarding information seeking could also impact their search queries [13]. However, these motives are often not sufficiently taken into account when studying WHIS behavior.

Finally, in the period between diagnosis and cure or remission, patients often experience a range of emotions, including (but not limited to) uncertainty, hope, fear, and anxiety. These feelings and emotions are important motivators for many patients to seek out information to cope with their illness [14]. For example, when just diagnosed with cancer, individuals might be concerned about the unpredictable aspects of the disease, leading them to search for information to better manage and cope with their newly discovered illness. Apart from instigating patients' WHIS behavior, these emotions may also influence decisions to continue, expand, or terminate WHIS [10,14-16]. Earlier qualitative studies have identified various WHIS patterns and the emotions associated with them, ranging from intense to guarded information seeking [10,16,17]. While all participants in these studies expressed a desire for basic information about their diagnosis, they also exhibited diversity in their motivations for seeking cancer information; the emotions experienced; and the nature, quantity, and sources of the sought information, along with the strategies used to manage this information. However, interviews rely on patients' subjective, retrospective reporting and, therefore, do not provide a comprehensive overview of WHIS behavior.

Hence, it is thus far largely unknown how various motives and emotions guide WHIS behavior in various phases of the cancer disease trajectory, whereas such insights can lead to better designed web-based health platforms catering to patients' changing requirements and supporting them effectively throughout their health journey. In addition, having a comprehensive understanding of how patients navigate information acquisition on the internet is crucial for establishing effective patient-provider communication that accommodates patients' specific needs. These insights may also make health care providers aware of the potential impact that WHIS has on patients and, consequently, on the consultation.

XSL•FO
RenderX

Objectives

Studying the impact of motives and emotions on information-seeking behavior during the disease trajectory poses several challenges that have not been taken into account in previous studies. First, as most WHIS occurs in private settings, such as at home, most of these studies use data collection methods that rely on patients' subjective, retrospective reporting, such as surveys, focus groups, and interviews. Using these retrospective methods presents significant drawbacks, including recall bias, which may lead to inaccurate results [18]. In particular, information collected before or during diagnosis is considered challenging as this often entails a short and stressful period for many patients [19]. New research methods such as the think-aloud method enable participants to verbalize what they are thinking and doing while performing a certain task [20]; this allows researchers to observe patients' WHIS more precisely. This includes assessing attention to web-based information, choices made while selecting information, and people's thoughts and feelings evoked during exposure to information [21]. When combining the think-aloud method with vignettes representing different scenarios at various stages of the disease trajectory, research has the potential to provide a more comprehensive and naturalistic view on the WHIS of patients with cancer. Therefore, this study aimed to explore patterns of motivations and emotions behind the web-based information seeking of patients with cancer at different stages of their disease trajectory, as well as the cognitive and emotional responses evoked via a scenario-based, think-aloud approach. This study adopted a unique explorative approach by observing analog patients (ie, patients or healthy participants putting themselves in the position of a patient [22]) as they engaged in WHIS during different phases of their disease trajectory.

Methods

Study Design, Setting, and Population

We used a scenario-based, think-aloud approach followed by a semistructured interview to obtain more in-depth information regarding analog patients' search strategy, their reasoning and emotions behind this strategy (ie, motives), and the emotions experienced throughout. To increase feasibility and for ethical reasons, we decided to rely on analog patients (patients or healthy participants who are asked to imagine themselves in the role of the patients), who are considered valid proxies for clinical patients [23,24]. The COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines were used to report the methods (Multimedia Appendix 1).

Analog patients were recruited from a local panel of patients with cancer, survivors, and their informal caregivers who were willing to participate in scientific research on patient-provider communication and health information provision [25]. In this way, we ensured that the analog patients had some personal experience with cancer. Via email, panel members were informed about the study purpose and invited to complete a screening questionnaire to establish their eligibility, that is, whether they were aged ≥18 years, had previously used the internet to search for health information, and owned a computer or laptop with internet connection. The screening questionnaire also included panel members' age, gender, and educational attainment to allow for purposive sampling based on these characteristics as research shows that individuals differing in these characteristics navigate the web differently and differ in information needs [26]. In addition, we strived for diversity in relation to cancer experience (eg, "I have (had) cancer" or "My partner has (had) cancer"), cancer type, and frequency of using the internet for health information in the previous year (eg, "1-5 times," "6-10 times," "11-30 times," or "more than 30 times").

In total, 75 panel members indicated an interest in participating. Of these 75 members, we invited 34 (45%) individuals based on purposive sampling to take part in the scenario-based, think-aloud study. Eventually, of the 34 individuals, 5 (15%) participated in the pilot study, and 15 (44%) participated in the think-aloud sessions, 5 (33%) for each scenario. Among the 34 individuals, there were 9 (26%) nonresponses, 1 (3%) failed recording, and 4 (12%) who opted out.

Procedure

The scenario-based, think-aloud sessions were conducted between May 2021 and December 2021 by 3 researchers (PK, FH, and an undergraduate student). PK and the student have a health communication background, and FH has a health science and health care management background. PK is trained in qualitative research. Due to the COVID-19 pandemic, the sessions were held on the web using videoconferencing software (ie, Zoom [Zoom Video Communications] or Microsoft Teams [Microsoft Corp]) and were recorded with video. Analog patients could participate in the sessions from the comfort of their home while using their own devices, thereby enhancing ecological validity.

We used a protocol for the scenario-based, think-aloud sessions, including a semistructured interview guide. This protocol was pilot-tested with 15% (5/34) of the analog patients. On the basis of the pilot, we decided to develop a video tutorial explaining the think-aloud procedure and a written manual explaining the use of the videoconferencing software (eg, "How do I share my screen?"). We also adapted the interview guide by adding questions focusing on analog patients' explanations of and reflections on their WHIS behavior (Multimedia Appendix 2). Participating analog patients received an email including an information letter and the video tutorial.

At the start of each session, the researcher explained the nature of the scenario-based, think-aloud method to the analog patients and asked for their personal experience with WHIS. Then, to become familiar with the process of thinking aloud, the analog patients were presented with a practical task (ie, to find a recipe for a pie or a cake containing apples) [27].

After familiarizing the analog patients with the think-aloud procedure, the researcher asked them to imagine themselves in one of the three following scenarios: (1) being an individual who experienced symptoms that could point toward non-Hodgkin lymphoma (NHL), hereinafter referred to as analog prediagnostic patient; (2) being a patient who is about to receive treatment for NHL, hereinafter referred to as analog patient with cancer; or (3) being a survivor of NHL 2 months after having finished treatment, hereinafter referred to as analog survivor of

XSL•FO
RenderX

cancer (Multimedia Appendix 3). We use the general term *analog patients* when referring to 2 or 3 scenarios.

Each scenario was based on real patient experiences that were reported in blogs and discussion groups of the largest cancer-related website in the Netherlands [28] and was reviewed by a survivor of cancer to optimize external validity [29]. Analog patients were assigned to the scenario that was most appropriate given their health status and relationship to cancer.

To enhance identification, analog patients were asked to report in their own words what they had just heard in the scenario. In addition, the researcher asked analog patients to discuss any thoughts or feelings that were evoked by the scenario and score their stress, anxiety, worries about cancer, hope, and uncertainty on an 11-point thermometer-style scale (0=*not at all*; 10=*an extreme amount*). Next, analog patients were asked to go on the web imagining themselves as the described patient in the scenario. While performing the various tasks, analog patients were asked to share their screen. The researcher instructed analog patients to indicate when they wanted to stop their web-based search. If analog patients fell silent during the session, the researcher reminded them to voice their thoughts.

After the think-aloud process, a short semistructured interview was conducted in which the researchers probed for analog patients' motives (eg, what made them choose particular search terms or why they decided to end their search) and their satisfaction with the content (Multimedia Appendix 2). Each interview session ended with a questionnaire assessing the analog patients' coping style (Dutch Threatening Medical Situations Inventory [30,31]), uncertainty intolerance (Dutch version of the short Intolerance of Uncertainty Scale [32]), information needs [33], and eHealth literacy (Dutch eHealth Literacy Scale [34]). These measures were used to be able to describe the sample.

Data Analysis

In total, 2 coders (FH and PK) first familiarized themselves with the data by watching the recordings and reading the interviewer field notes. Second, they independently selected and transcribed parts of each recording that seemed relevant to the research questions (eg, motives and emotions related to WHIS and search strategies). During the analysis, they focused on the analog patients' actions (observations), their verbalized thoughts during the scenario-based, think-aloud process (what they did vs what they said), and their reflections (interview). What was considered relevant was first discussed with a third team member (AL). Third, the coders independently double coded all relevant fragments. Fragments were coded inductively based on the sensitizing concepts as discussed in the introduction (ie, emotions and motives to seek web-based health information, search strategy used, and type of emotions evoked). During the observations, the coders closely examined the search terms used by the analog patients and the content viewed to deduce the analog patients' underlying motives. Fourth, the coders met and discussed their codes after each session to reach an agreement on the coding scheme together with a third team member (AL). Fifth, after completion of the coding process, the codes were aggregated into potential overarching themes and subthemes through comparisons and discussion between the coders. To improve reliability, validity, and generalizability, the results were substantiated using vivid quotes, and a continuous process of reflection and discussion among the coauthors (FH, PK, AL, and ES) was used. To improve the readability of the overall analysis (N=15), we decided to use the term *most* when the analysis applied to >10 analog patients, *several* when it applied to between 5 and 10 analog patients, and *some* when the analysis applied to <5 analog patients. For scenario-specific analysis (5/15, 33%), we decided to use the term *most* when the analysis applied to 3 or 4 analog patients and the term *some* when the analysis applied to 2 analog patients.

Ethical Considerations

The Amsterdam School of Communication Research Ethical Review Board approved this study at the University of Amsterdam (ethics approval code: 2021-PC-13493). Informed consent was verbally obtained from analog patients at the start of the scenario-based, think-aloud session. Analog patients could withdraw their consent at any time. The data could not be anonymized as the think-aloud interviews were video recorded. The data are saved on a secured drive of the Amsterdam University Medical Center. No compensation was provided to the participants.

Results

Sample Characteristics

Among the 15 participating analog patients (n=9, 60% women and n=6, 40% men), the ages ranged from 28 to 72 years (mean 56.9, SD 12.5 years). Most were former patients with cancer and reported having used the internet for seeking health information >6 times in the foregoing year. In total, the sessions lasted between 25 and 70 minutes, and the web-based search lasted between approximately 6 and 26 minutes. The number of web pages visited ranged from 3 to 15 per session, and changes in search terms ranged from 1 to 16 per session. Table 1 shows the sample characteristics, and Tables 2-4 provide descriptions of the individual search sessions.

Start of the Search Session

Analog patients reported starting their search session with various associations and reactions evoked by the scenario. For example, in the scenario in which they were experiencing symptoms, analog prediagnostic patients were immediately worried about cancer or felt alarmed by specific symptoms. This was reflected in their search terms, showing a predominant focus on searching for information about these symptoms. This was also reflected in their thoughts as patients expressed concern about the symptoms. Whenever the general practitioner in the scenario showed concern, analog patients more often showed signs of feeling distressed:

> *The word tumor immediately pops into my mind. This is serious. These are symptoms I would not trust.* [S01; analog prediagnostic patient]

> *You do not immediately think the best, especially sweating attacks and weight loss are warning signs.* [S05; analog prediagnostic patient]

Most analog patients with cancer assigned to the scenario of undergoing cancer treatment started their search by expressing fear about the upcoming challenges, particularly the apprehension of chemotherapy, and harboring doubts about the effectiveness of the treatment. The aggressive nature of NHL added to their anxiety, with a lack of optimistic information causing visible distress and confusion about the treatment process:

XSL•FO
RenderX

> *I am scared of what's coming and scared of the chemo. And I am not so hopeful because of my doubt whether the treatment will work.* [S27; analog patient with cancer]

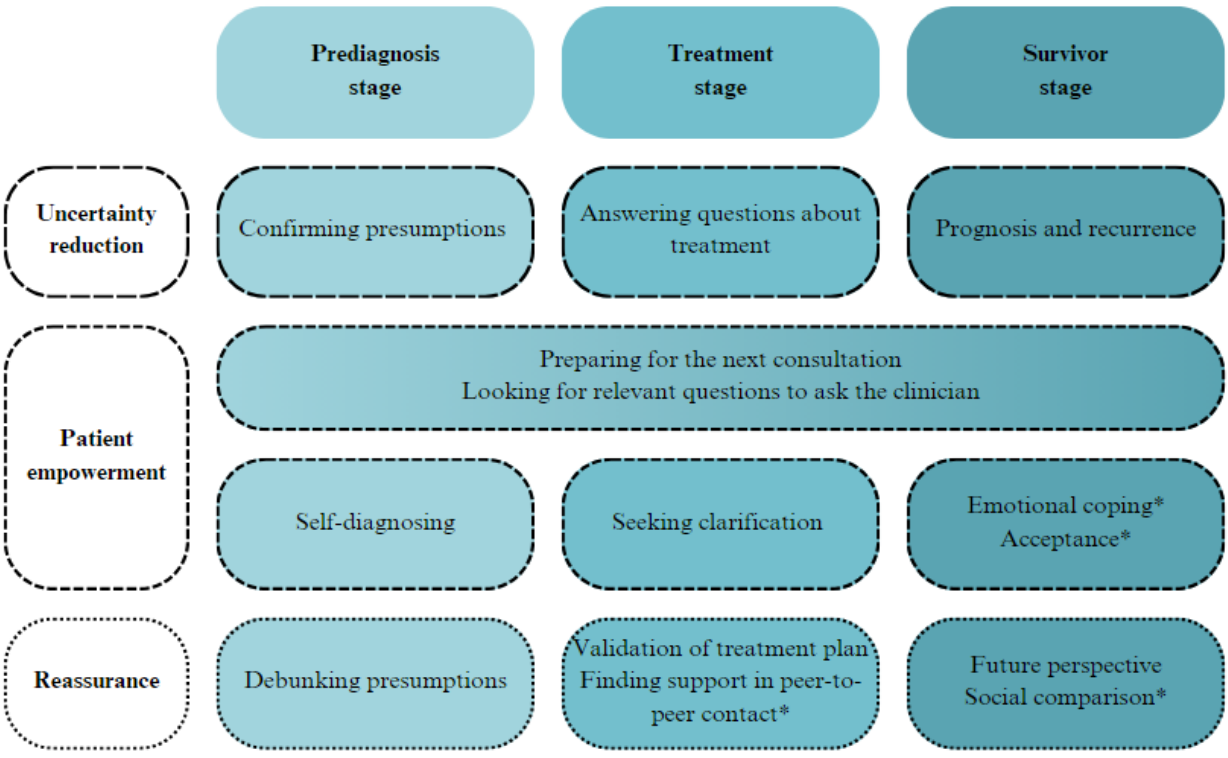
Despite these negative emotions, some analog patients with cancer still remained combative or hopeful:

> *Damn, I have cancer again, now I have to have another treatment, but well I am going for it, because I am far from finished living.* [S25; analog patient with cancer]

This fear was also reflected in their search, with all analog patients with cancer being prone to mainly focus on using search words that were used in the scenario (*(aggressive) non-Hodgkin* and *R-CHOP* [rituximab, cyclophosphamide, hydroxydaunorubicin, oncovin, and prednisone regimen]).

Finally, those who were allocated to the survivor case ("analog survivors of cancer") generally voiced uncertainty at the beginning of the search about whether the cancer was definitely gone. They showed concerns about cancer recurrence and recovery and were somewhat skeptical about recovery:

> *Should I really be happy with being cancer-free? What if it comes back? Before this, I had not felt anything. Now, I do not know what I should and should not feel anymore.* [S32; analog survivor of cancer]



Analog survivors of cancer voiced that, most of all, they wanted to return to their normal lives before the diagnosis and, accordingly, started with search terms related to this desire to get back to the normality of their lives (eg, *out of cancer treatment, what now?*).

Search Motives

Overview

On the basis of the search strategies observed and the thoughts voiced, we were able to distinguish 3 overarching motives guiding patients' WHIS. These overarching motives were prevalent regardless of the allocated stage in the disease trajectory. Each overarching motive was expressed differently throughout the various disease stages (Figure 1). The first motive was *uncertainty reduction* to cope with the anxiety and health threats as most analog patients started their search by expressing uncertainty about what was going to happen to them. The second motive was *empowerment* (ie, "the process of increasing the capacity of individuals (or groups) to make choices and to transform those choices into desired actions and outcomes" [35]) as most analog patients searched content to pursue an active role in their own care process, for example, by actively preparing for the next consultation and looking for relevant questions to ask the clinician. The third motive was *finding reassurance* as analog patients wished to find content that would give them some hope. The 3 overarching motives were not mutually exclusive; they could go hand in hand.

Figure 1. Expressions of the 3 overarching motives for web-based health information seeking—uncertainty reduction, patient empowerment, and reassurance—within the 3 disease stages (prediagnosis stage, treatment stage, and survivor stage). *Affective needs (ie, need to be understood).

Motives in the Prediagnosis Stage

Analog prediagnostic patients wanted to diminish their anxiety and reduce their uncertainty by starting their search with confirming their presumptions. One analog prediagnostic patient immediately used the search term *characteristics cancer*, looked on different websites to compare symptoms, and said the following at search onset:

XSL•FO
RenderX

> *You do not know anything for sure...Apart from the fact that I initially think it is cancer, I still want to confirm that by searching the internet.* [S10; analog prediagnostic patient]

Furthermore, they mostly used the internet to empower themselves by attempting to self-diagnose and prepare for the next consultation. When trying to self-diagnose, they used symptom-related search terms, such as *fatigue*, *swollen glands*, *(unexplained) weight loss*, and *night sweats*. After encountering content about possible diagnoses, some changed their search terms to *symptoms of non-Hodgkin* and *symptoms of cancer* while simultaneously explaining this change:

> *I am actually finding several causes now and cancer is also mentioned. However, I am not quite happy with the information I'm getting yet. But since cancer has come up a few times, I am going to search for symptoms of cancer, so I'm turning it [the search terms] around now [searches for: symptoms of cancer].* [S06; analog prediagnostic patient]

The motive *empowerment* was apparent in one analog prediagnostic patient who used the search terms *preparing consult internist* and read the text *What can you do to prepare for the first visit with an internist?*:

> *What I would do now, because I am going to the hospital, is that I am going to prepare. So, I am now going to search on prepare consult internist. I think I am going to an internist, but obviously I'm not sure yet. [reads text on how to prepare for a visit] I would also like to know, what are useful questions? [clicks on other website] Okay, I have pretty much got everything now I need to consider, only I have to go through the 3 good questions again which I can ask the internist [opens the online brochure about 3 good questions].* [S06; analog prediagnostic patient]

The extent to which analog prediagnostic patients in this phase narrowed down their search to know their exact (possible) diagnosis differed. Some searched various options related to the symptoms, one settled for the likely diagnosis "cancer," whereas others continued their search until they had a specific idea about the type of cancer. Those who searched for various possible diagnoses wanted to be reassured that the symptoms could be anything other than a serious illness such as cancer. They tried to debunk their presumptions, as reflected in the following observation and quote:

> *[reads content about causes of swollen lymph nodes] Infection, which could also be, that makes sense. Then I see here swollen nodes due to a systemic disease. Then I am thinking about Lyme disease, okay. That is different from a tumor. Autoimmune disease is potentially on the table. I already see that swollen nodes can be caused by many factors, which is somewhat reassuring.* [S01; analog prediagnostic patient]

Motives in the Treatment Stage

Analog patients with cancer mostly appeared to use the internet to answer their remaining questions to reduce uncertainty. Reducing uncertainty seemed to be combined with increasing their feeling of empowerment as they appeared to seek for more clarification about diagnosis and treatment. Both uncertainty reduction and empowerment were reflected in search terms such as *What is non-Hodgkin lymphoma?*, *R-CHOP*, *side effects*, and *immunotherapy* (ie, cognitive needs). While searching these terms, they said the following:

> *More than 50% of patients with an aggressive non-Hodgkin lymphoma in an advanced stage are cured after treatment with R-CHOP. Okay, that is quite a lot. But, hmm, yes, the other half does not. It is not clear to me whether the half that does not recover remains chronically ill or simply succumbs to death. I would like to know that in that sense.* [S28; analog patient with cancer]

The motive to obtain reassurance via web-based information was reflected in analog patients with cancer using the internet to validate whether the treatment (as being proposed in the scenario) was indeed the right treatment for them. They specifically searched for websites and information that would convince them of this treatment being the best option:

> *And I would definitely, before starting that treatment, request a second opinion from another institution to ensure that I...um...yes, receive the correct diagnosis or the right treatment [searches for other hospitals].* [S24; analog patient with cancer]

One analog patient with cancer also seemed to use the internet to obtain reassurance via socioemotional content. This was reflected in the search term *experiences with R CHOP*. Of note, none of the analog patients with cancer used search terms indicating a need to know more about the prognosis of NHL.

Motives in the Survivor Stage

Analog survivors of cancer seemed to use the internet to reduce uncertainty only to a limited extent. When they used the internet for that purpose, they wanted to know more about prognosis and recurrence, as reflected in search terms such as *prognosis*, *late effects*, and *what to expect*. While using these search terms, they said the following:

> *Yes, you are quite uncertain about how everything will unfold. There are still quite a few questions, and that diminishes over time, but especially in the beginning after that hospital period, you still have quite a lot of questions.* [S37; analog survivor of cancer]

Analog survivors of cancer mainly used the internet to search for socioemotional content related to pursuing an active role in their own recovery (ie, patient empowerment). This was reflected in search terms regarding feelings, experiences, and emotions (eg, *uncertainty after cancer* and *feelings after non-Hodgkin treatment*). Pursuing an active role in their own recovery mainly encompassed (emotional) coping and finding acceptance (eg, returning to their normal life before diagnosis). Apparently, to satisfy these motives, they often visited blogs of survivors of cancer writing about feelings and experiences and providing advice on coping with survivorship (eg, *how to deal with emotions/fatigue/work/daily life*). Some searched for

XSL•FO
RenderX

psychologists or for recovery programs offered by patient organizations or hospitals, which could also be seen as an expression of empowerment:

> *Not because I do not trust my own hospital, but I just want to look further. What do other hospitals offer their patients? Is there anything I can take advantage of?* [S32; analog survivor of cancer]

To a lesser extent, analog survivors of cancer went on the web to seek reassurance about their future. They seemed to be reassured when encountering people with similar experiences. For example, one survivor stated the following:

> *Okay, I found something here, there are more people like me. Shared sorrow is half sorrow.* [S34; analog survivor of cancer]

Overall WHIS Patterns

The web-based source that analog patients eventually selected seemed to depend on their cancer-specific knowledge, cancer-related experience, and search experience. The use of cancer-specific knowledge and experience was reflected in selecting familiar and well-known websites about cancer. The use of search experience was reflected in analog patients using strategies that they reported to prefer (eg, preferring to use the search bar on specific websites instead of the regular search engine or the other way around). Analog patients mentioned different reasons for selecting content. The most prevalent reasons were familiarity with a website or organization (eg, the Dutch Cancer Society) or previous experience with a website. Some also mentioned that they selected certain websites as part of habitual behavior rather than for specific reasons. Notably, analog patients also visited websites while voicing doubt about their trustworthiness. It seemed that those analog patients thought that it was more important to find information relevant to fulfill their motives than looking for trustworthy information.

WHIS Approaches

In total, 2 overarching WHIS approaches could be identified: explorative and focused. Explorative approaches consisted of spontaneously selecting information seemingly without having an explicit information need. Analog patients who used this explorative approach mainly guided their searches by clicking on referral links and using suggestions made by search features on Google, such as the *autocomplete* (a feature within Google Search that makes it faster to complete searches that users start to type. Google's automated systems generate predictions that help users save time by allowing them to quickly complete the search they already intended to do) and *people also ask* (a feature within Google Search that provides users with additional questions related to their original search query and quick answers to them) functions. Analog patients were considered to use a focused approach when they seemed to search more purposefully (ie, mainly selecting information aligned with their verbally expressed specific information needs). For instance, an analog prediagnostic patient searched *symptoms of cancer* and exclusively selected content related to these search terms.

Unlike analog patients using an explorative approach, patients using a focused approach only made use of Google features when these explicitly helped them meet their self-reported information needs. For example, an analog patient with cancer searched for and read information about R-CHOP and subsequently encountered the following suggestions from the Google feature *people also ask*: *What does R-CHOP mean?* and *What is a CHOP cure?*

Several analog patients used both explorative and focused approaches. Some started with a clearly focused search strategy based on an information need but appeared to become emotionally distracted by the encountered content and started to use a more explorative approach. Others started with an explorative approach and were triggered by specific content that led them to adopt a new, more focused approach (eg, understanding difficult, complex words or confirming assumptions). In other words, information needs evolved while searching. WHIS approaches seemed independent of the disease stage that analog patients were allocated to.

Dissatisfying Content

All analog patients came across dissatisfying content while searching (in other words, content that did not satisfy the wishes of the patients). Examples of dissatisfying content were difficulty navigating systems on websites, cookies, or information not being in line with search motives. When this dissatisfying content was encountered, analog patients most often changed their search terms or quickly moved on to other web pages (the number of web pages visited ranged from 3 to 15 per session). Search terms were frequently changed during a search session (range 1-16 times per session), mostly because of dissatisfying content:

> *So, I'm not getting anywhere with this either, because I don't need to know what the cancer looks like...So I guess I'm not getting anywhere with this search term, with the search things. Uhm how am I going to do that?* [S35; analog survivor of cancer]

Impact of WHIS on Emotions and Dealing With Content

Emotions

Regardless of the stage of the disease, emotions were present throughout the entire search process, ranging from anxiety and worry to hope. These emotions fluctuated, and negative emotions were often induced when confrontational, complex, or unwanted information was found. Confrontational content included information on symptoms suggesting cancer or thyroid problems, information on treatment side effects such as hair loss and nausea, or a confronting picture:

> *I am not happy with the image I see here. That photo confirms the nightmare I have about chemotherapy. This is someone surrounded by nurses, being injected, and she has no hair, so that picture embodies for me everything that is wrong with this disease in one image. They have succeeded very skillfully in capturing all of that in one photo, but I do not think that was the intention of the person who took the photo. However, that is how it comes across at me: the embodiment of a mountain of misery.* [S27; analog patient with cancer]

XSL•FO
RenderX

Complex information included content containing medical jargon, such as *malignancies*; *cachexia*; or drug names such as *rituximab*, *cyclophosphamide*, and *hydroxydaunorubicin*. Most analog patients seemed to be affected by complex words:

> *This is getting annoying because I already see a word here that I do not know at all. I'm getting a lot of medical terms here that do not mean much to me...* [S06; analog prediagnostic patient]

Sometimes, positive emotions emerged from information that gave hope (eg, indolent NHL more often has a chance of recurrence than aggressive NHL). Moreover, analog patients who doubted their own navigation skills while searching on the web reported high levels of distress. Some of the analog patients also experienced cognitive dissonance (ie, a mental state of having conflicting beliefs, thoughts, values, or attitudes), as reflected in the following quote:

> *Everything in you says that it is better not to click on it, because you don't want to know it. But if you see the option then you just need to click on it.* [S27; analog patient with cancer]

Dealing With Emotionally Difficult Content

When encountering cognitively or emotionally difficult (or unwanted) information, analog patients with cancer dealt with the content in various ways. They adapted their search strategy, ignored the information by quickly clicking away from it and shifting toward other information, or stopped searching:

> *I immediately find myself with types of cancer, um...all the hits are related to Hodgkin; [scrolling back and forth through search results on the first Google page, but not clicking on anything]. Yes, I find this difficult; I think I will check the next Google pages to see what else comes up, what comes after Hodgkin.* [S01; analog prediagnostic patient]

Several analog patients also mentioned that they would normally seek information multiple times briefly or seek a distraction from the confronting information, such as watching Netflix or having some tea.

End of the Search

As mentioned previously, one of the reasons to stop searching was encountering cognitively or emotionally difficult information (confronting, upsetting, or confusing). This was mostly the case for analog prediagnostic patients and analog patients with cancer. The following quote illustrates this "overload":

> *Nothing [information found] makes me happy. Yeah, you can find information, but I believe I would make a cup of coffee now. I cannot say I'm a lot wiser now.* [S25; analog patient with cancer]

Another reason to stop searching was that analog patients saw their health care provider as a gatekeeper and their primary source of information about their disease and treatment. During the interview, they indicated that they preferred to talk with their clinician to clarify the encountered information instead of looking for more web-based information:

> *I believe that this information is quite overwhelming me right now, so I would put it away for a while. And I would talk it through first at a subsequent consultation with my doctor before I start worrying and assuming things that are not an issue at all...So, I think I will stop looking for now until I have spoken to the doctor again. It is a lot of information, and it is also complicated. So, I want to consult the doctor first.* [S23; analog patient with cancer]

All analog patients with cancer indicated ending their search sessions with many unanswered questions and an increase in uncertainty (compared to the start of the search). Unlike analog patients with cancer, analog prediagnostic patients and analog survivors of cancer ended their search more often with their information needs being fulfilled, as reflected in the following quote during the interview:

> *I do think it is very true. I'm at a point now where I do think: yeah, I'm reading this now, I'm not really getting very comfortable with this. I do not think there is any point in continuing to search now. I think I am now on a trustworthy site, and I find this a very upsetting story now that I see this. I cannot do much but wait and see. I don't know if I'm happy I've figured this out now...* [S01; analog prediagnostic patient]

Compared to analog patients in other disease stages, analog survivors of cancer ended their search most often satisfied and with more positive emotions; they felt less uncertain and found useful (practical) information on ways to cope with the future:

> *I definitely did become a bit wiser, because I can move on: I can go to physio, psychologist and I have a phone line which I can call.* [S36; analog survivor of cancer]

Discussion

Principal Findings

Using a comprehensive scenario-based, think-aloud approach, we were able to show that (1) patients' overarching motives for WHIS were mainly to reduce uncertainty, obtain reassurance, and increase empowerment; (2) these motives differed depending on the disease stage (at the beginning of the disease trajectory, patients mainly showed cognitive needs, whereas this shifted more toward affective needs in the subsequent disease stages); (3) analog patients' WHIS approaches varied from exploratory to focused to a combination of both; and (4) positive (hope and reassurance) and negative (anxiety and worry) emotional responses played an important role in patients' search strategies.

We found 3 overarching motives (ie, reducing uncertainty, obtaining reassurance, and increasing empowerment) for patients to search on the web. With these findings, we not only confirm the problem-solving model in the context of patient motivations to go on the web throughout their illness journey but also extend this model. According to Wilson [36], the process of problem-solving is the result of patients' wishes to reduce uncertainty. Patients' uncertainty at either the prediagnosis or

XSL•FO
RenderX

treatment phase concerned various topics, clearly showing that these motives change over time. However, we also discovered 2 other important motives for patients to engage in a problem-solving process, namely, reassurance and empowerment [36]. In addition, the study's findings revealed a potential conflict between patient empowerment and uncertainty reduction in the context of WHIS. When patients seek web-based information to empower themselves, they gain a better understanding of their situation, which could enable them to ask informed questions to their clinicians. However, this increased knowledge may also give rise to new questions and uncertainties, leading to a potential challenge in fulfilling the motive of uncertainty reduction.

Moreover, our findings provide insights into the search behavior of patients with cancer at various stages of their disease trajectory and how these behaviors vary. In the initial phase of prediagnosis, patients often engaged in self-diagnosis. The results of this study extend those of previous research [9] by showing that patients prepare for a consultation by using the internet not only to help them formulate questions but also to self-diagnose. Despite the popularity of this search approach, research on self-diagnosing remains limited. In the context of web-based self-diagnosis for minor ailments, research shows that using the internet for self-diagnosis can be helpful as 44% of participants achieved accurate final diagnoses after searching the internet compared to 11% before searching the internet [37]. Another study shows that web-based self-diagnosing has the potential to empower patients in appraising and challenging clinicians' advice and requesting further diagnostic procedures [38]. However, web-based self-diagnosis can also be counterproductive if the patient misdiagnoses themselves, leading to unnecessary concerns. In addition, problems may occur if patients visit their clinician with a preconceived diagnosis, potentially causing disagreements about their condition [39]. During the treatment phase, the search strategy of patients with cancer focused on cognitive needs by seeking clarification, gathering more information, and preparing. However, we only observed a shift in search strategies toward affective needs by seeking emotional coping resources for dealing with the disease after patients completed treatments and were declared cancer free. In other words, at the beginning of the disease trajectory, analog patients had mainly cognitive needs, whereas analog survivors also showed affective needs and used the internet for emotional support. The change from more cognitive needs to more affective needs could be explained using the social-cognitive processing model. According to this model, seeking emotional support may facilitate emotional adjustment to traumatic experiences, such as cancer diagnosis and treatment [40]. Potentially, survivors have more mental space to cope with the situation and reflect on what has happened in the past months.

Our results further show that patients tend to use different search strategies: explorative, focused, or a combination of both. Previous research has demonstrated that individuals who are more exploratory seekers tend to tackle unfamiliar problems by using a broader search strategy (symptom exploration), resulting in a broader range of new information [37]. By encountering a broad range of information, patients are possibly confronted with new and unknown content, which could increase their level of uncertainty [41]. Our results also suggest that an exploratory search strategy increased the risk of being confronted with unwanted information. On the other hand, those who are more focused seekers tend to have a clear idea and a specific plan, leading them to research within a limited set of results (hypothesis testing) [37]. Such hypothesis testing can be problematic because it skews the way in which patients process information and distorts their perception of reality—a phenomenon known as confirmation bias [42]. It occurs when patients seek, interpret, or favor information that confirms their existing beliefs while ignoring or downplaying evidence that contradicts those beliefs [43]. Pang et al [41] argue that seekers within one internet visit alternate between exploratory and focused search strategies as new, unknown topics often lead to more exploratory searches. If the topic to be searched becomes clearer, the seeker may use a more focused approach. Our results confirm those of this previous study by showing that patients used both explorative and focused approaches. Some started with a focused search but became emotionally distracted and switched to an explorative approach. Others began exploratively and shifted to a focused search after encountering specific content.

Furthermore, our findings show that positive (hope and reassurance) and negative (anxiety and worry) emotional responses were present before, during, and after the search sessions. On the basis of patients' voiced thoughts and observed behavior, we conclude that these emotions impacted their search behavior. This is in line with the functionalist perspective of emotions, which argues that emotional responses may motivate people to behave in particular ways [44-46]. For instance, hope is seen as a motivating force that helps individuals move toward desired outcomes even in the face of uncertainty [47]. It is a future-oriented emotion as it involves visualization of positive future situations [48], and thus, hope could explain why patients are motivated to seek reassurance. Worry, on the other hand, is seen as an uncertainty-associated emotion and can increase a patient's desire for obtaining additional information [15]. Studies show a positive relationship between worry and the perceived need for additional information [49-51], and thus, worry could explain why patients are motivated to reduce uncertainty by searching for additional information. However, we also observed that patients who were worried ignored or avoided specific information. A possible explanation is that hope and worry are intertwined during WHIS [16]. Confronting or complex information poses a threat to hope, and thus, ignoring certain information may serve as a self-protective behavior to stay hopeful [16].

In our study, patients in the treatment phase were most worried after their search session. This is in contrast to existing literature indicating that perceived knowledge through web-based information seeking decreased patients' worry [15]. WHIS has also been found to help searchers fill information voids and enhance their coping abilities [52]. Although we did find some comparable results for the prediagnosis and survivor phases regarding decrease in worry and enhancing coping abilities, we did not find this for patients in the treatment phase. A possible explanation is that complex or confrontational information (eg,

XSL•FO
RenderX

jargon for medicines and treatments and intense side effects) may have induced worries in analog patients in this phase. This inconsistency with the existing literature could further be explained by our design, which involved one search session only at one specific moment rather than multiple search sessions by one individual patient. Possibly, patients who search for more information at multiple times will eventually be less worried as they become more familiar with the difficult and complex information. Therefore, future research should investigate the longitudinal search behaviors of individual patients during their disease trajectory and the effects of multiple shorter search sessions within a particular disease phase.

Limitations and Strengths

First, a strength of our approach is that we not only observed patients' WHIS behaviors but simultaneously gained insights into their thoughts. During the interview, the interviewer made use of techniques such as paraphrasing and checking to clarify the meaning of the interviewee, thereby enhancing the validity of our findings. This innovative, comprehensive scenario-based, think-aloud approach exhibits strength in its consideration of the intuitive nature of web-based searching while overcoming challenges such as recall bias in retrospective methods. However, certain limitations should be considered. Some remarks suggested that participants may have felt limited in their choice of search engine and might have perceived an obligation to use a specific search platform, such as Google. Furthermore, during the think-aloud sessions, participants did not explore the use of social media channels (eg, Facebook, Instagram, or Twitter [subsequently rebranded X]). Use of social media may have been limited as participants could perceive it as an intrusion into their personal lives. Another reason could be that these communication channels may represent more spontaneous ways through which patients acquire unplanned or unexpected web-based health information while scrolling through their social media timeline [53]. The scenario-based, think-aloud approach as used in this study does not provide any insights in how social media has an effect on patients' WHIS strategies, motives, and emotions. Furthermore, the relatively small sample size used in this study calls for caution when generalizing the findings. It is important to account for variations in patients' (eHealth) literacy, education, and cultural backgrounds [54]. Although previous research demonstrates overlap in WHIS among patients from different countries, it also identifies distinct country-specific differences even when the countries have comparable welfare and health status [5]. As this study was an explorative qualitative study, and despite our relatively small sample size, we believe we achieved thematic saturation during the iterative process as no new codes emerged toward the end of our analysis. Moreover, it is important to bear in mind when interpreting the findings that our sample consisted of analog patients who were presented with a scenario. This may have biased our results as using analog patients is different from using patients with NHL. However, participants in this study possessed preexisting familiarity with cancer; our sample consisted of patients with cancer (other than NHL), survivors of cancer, and informal caregivers of patients with cancer. Thus, this sample's strength lies in their ability to strongly identify with the scenarios presented, which is also reflected in their quotes, the emotions showed during the think-aloud process, and their scores on the thermometers [24]. Furthermore, participants possessed experience in web-based cancer information seeking. Many of them were acquainted with patient advocacy organizations, and a subset even served as administrators for certain web-based platforms dedicated to cancer information and peer support groups. In addition, they had previously encountered medical terminology in the context of their own medical conditions, thus acquiring a degree of familiarity with medical jargon. Consequently, our sample likely possessed a higher level of proficiency in navigating the internet for cancer-related information compared to the average patient with cancer. Despite their advanced familiarity with the subject, the results still indicated that patients encountered difficulties in navigating the internet and understanding medical jargon.

Practical Implications

Knowing how patients with cancer search for web-based health information is a first step toward optimizing web-based health platforms such that patients with cancer can (more) easily find and navigate through information that fits their needs. On the basis of the study results, there are various implications for the development of cancer websites. First, web-based health platforms could use less complex words and show content warnings about confrontational prognostic or side effect–related information on web pages. The latter could warn searchers about unwanted information, which is especially relevant for exploratory searchers. Second, websites should enable users to self-pace and allow for user-initiated tailoring (ie, allowing users to tailor the information themselves based on their information needs). For example, information should be minimalized, with the possibility to read more if wanted (eg, with the use of hyperlinks). Third, it should also be clear to the user whether platforms are expert generated or peer generated as these platforms differ in content focusing on cognitive needs (addressing the needs of analog prediagnostic patients and analog patients with cancer) and affective needs (addressing the needs of analog survivors of cancer) [13]. In the Netherlands, multiple cancer platforms already make use of such features, which patients in our sample experienced as convenient. In addition to these implications for websites, another important finding is that patients see their health care providers as their primary source of information when it comes to their disease and treatment. Patients indicated that they had various remaining questions and considerable uncertainty after their search, which they wanted to resolve during their interaction with their health care provider. Therefore, it is important that, within consultations, there is room for questions arising from WHIS. Furthermore, health care providers can guide patients in the search process by giving tips and tricks on how (not) to use the internet to search for health information and how to cope with any uncertainty that may result from such a search.

Conclusions

This study provides valuable insights into the real-time WHIS strategies of patients with cancer, the motivations behind seeking web-based health information, and the emotions experienced at various stages of the disease trajectory. Understanding patients' search patterns is pivotal in optimizing web-based

XSL•FO
RenderX

health platforms to cater to their specific needs. In addition, these findings can guide clinicians in directing patients toward reliable sources of web-based health information.

Acknowledgments

The authors would like to thank all participants for allowing them to watch how they searched the internet for health information while sharing their thoughts with them. Furthermore, the authors would like to thank Diana Aksan for her work in the selection process and pilot-testing of the protocol. This work was supported by the Dutch Cancer Society. No generative artificial intelligence was used in any portion of manuscript writing.

Data Availability

The datasets generated during and analyzed during this study are not publicly available due to the anonymity of the participants but are available from the corresponding author on reasonable request.

Authors' Contributions

The conceptualization of the study was carried out by ES, MH, JvW, and AL. ES acquired funding for this project. FH and PK gathered and analyzed the data, and AL was responsible for the validation process. The original draft of the manuscript was prepared by FH and AL. All authors reviewed the protocols, contributed to conceptualization and methodology, and reviewed the final manuscript.

Abstract

Background: YouTube is an increasingly used platform for medical information. However, the reliability and validity of health-related information on celiac disease (CD) on YouTube have not been determined.

Objective: This study aimed to analyze the reliability and validity of CD-related YouTube videos.

Methods: On November 15, 2023, a search was performed on YouTube using the keyword “celiac disease.” This search resulted in a selection of videos, which were then reviewed by 2 separate evaluators for content, origin, and specific features. The evaluators assessed the reliability and quality of these videos using a modified DISCERN (mDISCERN) score, the *Journal of the American Medical Association* (*JAMA*) benchmark criteria score, the usefulness score, video power index (VPI), and the Global Quality Scale (GQS) score.

Results: In the analysis of 120 initially screened CD videos, 85 met the criteria for inclusion in the study after certain videos were excluded based on predefined criteria. While the duration of the videos uploaded by health care professionals was significantly longer than the other group (P=.009), it was concluded that the median scores for mDISCERN (4, IQR 4-5 vs 2, IQR 2-3; P<.001), GQS (4, IQR 4-5 vs 3, IQR 2-3; P<.001), *JAMA* (4, IQR 3-4 vs 2, IQR 2-3; P<.001), and usefulness (8, IQR 7-9 vs 6, IQR 3-6; P<.001) of the videos from this group were significantly higher than those from non–health care professionals. Video interaction parameters, including the median number of views, views per day, likes, dislikes, comments, and VPI, demonstrated no significant difference between the 2 groups.

Conclusions: This study showed that YouTube videos about CD vary significantly in reliability and quality depending on their source. Increasing the production of reliable videos by health care professionals may help to improve patient education and make YouTube a more reliable resource.

KEYWORDS

gastroenterology; celiac; YouTube; internet-based information; medical information; health-related; reliability; validity; quality; videos; celiac sprue; sprue; gluten enteropathy; cross-sectional

Introduction

Celiac disease (CD) is an autoimmune disorder that occurs in genetically predisposed individuals as a result of the immune reaction to gluten, primarily affecting the small intestine [1]. Symptoms range from asymptomatic to digestive problems and nutritional deficiencies due to malabsorption of nutrients. Treatment includes a gluten-free diet [1]. Over the past few decades, CD has been estimated to affect around 1% of the world’s population [2]. Despite the increasing prevalence of

XSL•FO
RenderX

CD, the majority of the patients with CD remain undiagnosed [1].

In recent years, the internet has become an important source of health information for the public. It has been reported that 80% of internet users use social media (SM) platforms to get information about their disease. Patients with chronic diseases in particular are increasingly relying on SM platforms to manage their conditions [3]. In a recent study investigating the use of SM by patients with CD and parents of patients with CD, it was reported that 96% of participants used SM for disease management [4]. YouTube (Google), is one of the world's most popular video-sharing platforms. Currently, YouTube has more than 1 billion registered users, and billions of videos are watched every day, about 30 million of which are health-related. Health-related videos can be uploaded by anyone, but the content of these videos may contain inaccurate or misleading information without being reviewed by health care professionals.

There are studies in the literature evaluating the reliability and quality of YouTube videos for many diseases [5,6]. There are few studies evaluating CD-related YouTube videos [7,8]. However, one of these studies evaluated non-English language videos [8]. The other study did not measure CD-related YouTube videos with the tests developed for these studies and did not include videometric parameters (such as the number of likes and dislikes) in the evaluation [7]. Unlike previous studies, which either focused on non-English videos or lacked comprehensive quality metrics, this research provides a more robust and comparative analysis of CD-related video content on YouTube.

We could not find any studies in the literature that evaluated the reliability and validity of YouTube videos about CD. This study aims to evaluate the quality and reliability of YouTube videos about CD using validated scoring tools and detailed content analysis.

Methods

Study Design

In this cross-sectional study, videos were collected using the keyword "Celiac Disease" in YouTube's search engine on November 15, 2023. The search was conducted in a Google Chrome browser in incognito mode, logged out of any user account, and using a standard IP address in Turkey. This was chosen because it is the most common keyword that holistically assesses all aspects of the disease, such as clinical, pathogenesis, diet, and nutrition. YouTube's default relevance mode was used to simulate the average consumer's search habits. It is recognized that most viewers rarely venture beyond the first few pages of results. Therefore, the first 120 videos about CD were selected, similar to previous studies. Based on the search results, a total of 120 videos were saved for further analysis, ranging from the most viewed video to the least viewed video. Video sampling criteria were determined with reference to similar studies [5,9].

The following factors were considered as exclusion criteria in the research: (1) videos in languages other than English, (2) videos with muted or poor picture quality, (3) videos containing advertisements, (4) videos with content unrelated to CD, and (5) videos with repetitive content.

Data Review

Data such as video type (real and animation), video length (min), time since upload (d), number of views, number of daily views (number of views/d since upload), number of likes, number of daily likes (number of likes/d since upload), number of dislikes, and number of comments were recorded. In our study, we categorized video sources into two groups: educational content of health care professionals (doctors, academic institutions or professional organizations, and health-related websites) and personal narratives of non–health care professionals (patients, independent users). The videos were independently analyzed by 2 raters (YHP and REC) and coded according to the themes of "Educational content" and "Personal narratives." Discrepancies in coding were resolved through repetitive discussions and consensus, ensuring a reliable and consistent categorization process. This method of assessment has been used in similar studies of other diseases [10].

Video Usefulness

The usefulness score is a usefulness scale defined by Lee et al [11]. Each video is rated with a score between 0 and 10 depending on the content of the video, such as causes, symptoms, diagnosis, diagnosis, and recovery status. According to the total score obtained, it is categorized as follows: 0=not useful, 1-3=less useful, 4-7=useful, and 8-10=very useful.

Video Popularity

The video power index (VPI) developed by Erdem et al [12] shows the popularity of videos and has been used in many studies [9]. The VPI calculation is as follows: VPI=(×100/[number of likes+number of dislikes]) × (number of views/number of d since upload)/100.

Quality and Reliability Evaluation

The Global Quality Scale (GQS) assesses the quality by providing the interpretation and usefulness of the videos for patients based on the flow of information. GQS has a 5-point Likert structure according to the quality, flow, and ease of use of the analyzed videos [13]. As used in similar studies, scores 1-2 were considered as low quality (inadequate in terms of patient information, contains incomplete information), 3 as medium quality (video flow is poor, some information is available but important issues are not addressed), and 4-5 (contains sufficient and useful information for patients) as high quality [14].

The quality assessment included the *Journal of the American Medical Association* (*JAMA*) benchmark criteria for determining authorship, attribution, disclosure, and currency. Each of these criteria was given a score of 1, with a maximum score of 4 [15].

The mDISCERN scale developed by Charnock et al [16] and later adapted to YouTube videos by Singh et al [17] was used to assess the reliability of the videos. The mDISCERN scale consists of 5 questions and is a questionnaire about information sources, purpose, reliability, bias, additional sources, and areas of uncertainty. Each question can be answered yes or no. Each

XSL•FO
RenderX

yes answer is worth 1 point and 5 points represent the highest quality.

The video content was evaluated and graded according to the most recent American College of Gastroenterology guidelines for the management of CD [18]. These guidelines emphasize accurate symptom identification, diagnostic criteria, and effective dietary management strategies. Videos were scored for reliability, usefulness, and consistency with evidence-based practice.

Statistical Analyses

The SPSS (version 25.0 for Windows; IBM Corp) package program was used. Continuous variables were evaluated using the Shapiro-Wilk test to determine whether they were normally distributed. Continuous variables are reported as median and IQR, while categorical variables are presented as counts and percentages. Chi-square tests were used to analyze categorical variables and Mann-Whitney *U* test for numerical variables. The significance level was set at *P*=.05 for all analyses.

Ethical Considerations

The study adhered to the ethical standards outlined in the Helsinki Declaration and complied with national regulations in the respective field. Since the study did not involve the use of human or animal data, ethics committee approval was not necessary. This study analyzed publicly available YouTube videos. No identifiable personal data was used, and all results are presented in aggregate. Therefore, formal ethics approval was not required.

Results

Main Characteristics of Videos and Video Analysis

In total, 120 videos were analyzed and 85 videos met the study criteria and were included. A total of 35 videos were excluded from the study, including 2 non-English language videos, 13 videos with repetitive content, 12 videos with advertising content, and 8 videos with poor picture and sound quality. Most (22/85, 25.9%) were published by universities and other organizations, and most (50/85, 59%) were uploaded by health care professionals. A total of 68.2% (58/85) of the videos consisted of real images. Descriptive statistics of the above characteristics and other variables are shown in Table 1.

Table 1. Main characteristics of the analyzed videos. Categorical variables are expressed as n (%), and numerical variables are expressed as median (Q1-Q3).

Characteristics	Values
Source, n (%)

Content Analysis and Source Evaluation of Videos

In the health care professional group, most (37/85, 43.1%) of the videos were uploaded by universities and other organizations, whereas in the non–health care professional group, most (19/34, 55.9%) of the videos were uploaded by "patients" (*P*<.001). While the duration of the videos uploaded by health care professionals was significantly longer than the

XSL•FO
RenderX

other group (*P*=.009), it was concluded that the median scores for mDISCERN (4, IQR 4-5 vs 2, IQR 2-3; *P*<.01), GQS (4, IQR 4-5 vs 3, IQR 2-3; *P*<.001), *JAMA* (4, IQR 3-4 vs 2, IQR 2-3; *P*<.001), and usefulness (8, IQR 7-9 vs 6, IQR 3-6; *P*<.001) of the videos from this group were significantly higher than those from non–health care professionals. (Tables 2 and 3)

Table 2. The average scales of the analyzed videos.

Video scales	Values, median (IQR)
mDISCERN[a]	3 (3-4)
GQS[b]	4 (3-4)
JAMA [c]	3 (2-4)
VPI[d]	12.8 (4-33)
Usefulness	7 (5-9)

Themes Identified in Videos

From the 85 included videos, two major themes were identified.

Educational Content

These videos, primarily created by health care professionals, provided detailed information about CD symptoms, diagnosis, treatment, and long-term management. This category accounted for 59% (50/85) of all videos and demonstrated significantly higher scores in quality and reliability metrics (mDISCERN, GQS, *JAMA*, and Usefulness; *P*<.001).

Personal Narratives

Uploaded by patients or non–health care professionals, these videos focused on personal journeys, sharing challenges, and tips for living with CD. They received moderate interaction

XSL•FO
RenderX

metrics (likes, comments) but were lower in quality and reliability scores (P<.001).

Discussion

Principal Findings

In this study, we analyzed YouTube videos about CD, an important disease that can occur at any age. We found that CD videos uploaded by health care professionals were significantly more reliable, adequate, useful, and quality information sources than those uploaded by non–health care professionals. Another striking result of the study was that there was no difference in video interaction parameters between those with and without health care professionals as video sources.

Recently, SM has become a popular way to access medical information and knowledge. Patients with many chronic diseases, including CD, have been reported to use SM as a source of information since adolescence [19]. Especially YouTube, a video sharing website, has become an important source of information in the field of health. In a recent nationally based survey study, it was reported that younger patient groups and patients with chronic diseases such as hypertension, diabetes mellitus, and chronic lung disease were more likely to watch YouTube videos as a source of health-related information [20].

As in other chronic diseases, SM use among patients with CD and their families has become widespread in recent years [4]. When we consider the importance of increasing adherence to a gluten-free diet as well as the diagnosis, risk factors, and clinical presentation of the disease, access to real and adequate information through SM becomes even more important. In a recent survey of patients with CD, two-thirds of the patients used SM every day for an average of 60 minutes per day. The 3 most common reasons for using SM were researching gluten-free diet products, obtaining information about diet, and CD. In the study, it was stated that the most frequently used platform was WhatsApp (Meta), and it was suggested that YouTube usage was 4% [4]. Although this rate may vary according to regional and cultural differences, it is still a relatively low rate and suggests that the use of YouTube may be higher than this data. In another similar survey study conducted in Japan, 27% of more than 2000 participants with chronic diseases stated that they used the YouTube platform related to their disease [20].

One of the studies evaluating YouTube videos on CD was a study in which 100 videos were evaluated in 2019. In this study, it was examined whether there was a difference between sources in 31 different topics such as etiology, symptoms, diagnosis, and treatment of the disease, and it was stated that there was no significant difference in terms of content in all remaining topics except 3 [7]. However, none of the video reliability-efficacy tests used in our study were used in this study. Nevertheless, it differs from our study because it claims that there is mostly no significant difference between videos whose source is health care professionals and other videos in terms of topics. Another study in the literature evaluated Polish-language videos, so it does not seem possible to make a comparison with our study [8].

Among the videos analyzed in our study, the fact that the reliability, usefulness, and quality scores of the videos of health care professionals were significantly higher than those of non–health care professionals was also observed in similar studies evaluating other diseases [21]. One of the most remarkable findings of our study is that there was no significant difference between the groups in terms of views, likes, dislikes, and VPI. There are many factors that can contribute to this, such as the visual presentation of the video, the demographic and cultural make-up of the viewers, the video's viral status, and the influencer's effect [22,23]. In a recent study investigating the influencer effect on SM related to dermatology, it was shown that dermatologists without competence and certification had as high a level of interaction as those with competence and certification [23]. This finding shows us that videos that may be insufficient as a source of information may also have high interaction and accordingly may cause misinformation and negative effects on patients and their families.

Based on these findings, we believe that in order for YouTube to be an accurate source of information about CD, many organizations and institutions, such as professional associations and universities, should provide training for health care professionals to produce high-quality videos that can provide more interaction and raise awareness among health care professionals about this issue. On the other hand, it is also important to raise patient awareness of the possibility that patients may be exposed to misinformation when using YouTube. We think that more use of YouTube and other SM platforms by health care professionals and peer review of health-related video content may reduce misinformation.

Limitations

There were some limitations in our study. The first 120 videos searched with the keyword "Celiac disease'" in the search results were analyzed and the other videos were not analyzed. In addition, since YouTube is a dynamic SM platform, video interaction parameters such as daily views, likes, and dislikes can change every day. Finally, the fact that only English videos were analyzed in our study can be considered among the limitations.

Conclusions

This study showed that YouTube videos about CD vary significantly in reliability and quality depending on their source. Increasing the production of reliable videos by health care professionals may help to improve patient education and make YouTube a more reliable resource.

Abstract

Background: The worldwide effects of the COVID-19 pandemic have been profound, and the Arab world has not been exempt from its wide-ranging consequences. Within this context, social media platforms such as Twitter have become essential for sharing information and expressing public opinions during this global crisis. Careful investigation of Arabic tweets related to COVID-19 can provide invaluable insights into the common topics and underlying sentiments that shape discussions about the COVID-19 pandemic.

Objective: This study aimed to understand the concerns and feelings of Twitter users in Arabic-speaking countries about the COVID-19 pandemic. This was accomplished through analyzing the themes and sentiments that were expressed in Arabic tweets about the COVID-19 pandemic.

Methods: In this study, 1 million Arabic tweets about COVID-19 posted between March 1 and March 31, 2020, were analyzed. Machine learning techniques, such as topic modeling and sentiment analysis, were applied to understand the main topics and emotions that were expressed in these tweets.

Results: The analysis of Arabic tweets revealed several prominent topics related to COVID-19. The analysis identified and grouped 16 different conversation topics that were organized into eight themes: (1) preventive measures and safety, (2) medical and health care aspects, (3) government and social measures, (4) impact and numbers, (5) vaccine development and research, (6) COVID-19 and religious practices, (7) global impact of COVID-19 on sports and countries, and (8) COVID-19 and national efforts. Across all the topics identified, the prevailing sentiments regarding the spread of COVID-19 were primarily centered around anger, followed by disgust, joy, and anticipation. Notably, when conversations revolved around new COVID-19 cases and fatalities, public tweets revealed a notably heightened sense of anger in comparison to other subjects.

Conclusions: The study offers valuable insights into the topics and emotions expressed in Arabic tweets related to COVID-19. It demonstrates the significance of social media platforms, particularly Twitter, in capturing the Arabic-speaking community's concerns and sentiments during the COVID-19 pandemic. The findings contribute to a deeper understanding of the prevailing discourse, enabling stakeholders to tailor effective communication strategies and address specific public concerns. This study underscores the importance of monitoring social media conversations in Arabic to support public health efforts and crisis management during the COVID-19 pandemic.

KEYWORDS

topic modeling; sentiment analysis; COVID-19; social media; Twitter; public discussion

Introduction

Background

Throughout history, humanity has faced numerous outbreaks of infectious diseases that have resulted in significant loss of life and economic impact. Toward the end of 2019, the World Health Organization reported a series of pneumonia cases in Wuhan, which were later identified as COVID-19. As a novel infectious disease transmitted through respiratory droplets and contact, COVID-19 quickly spread across the globe, leading to an unprecedented impact on global public health, businesses, and economies. As of February 7, 2023, there have been >676 million confirmed cases and 500,000 reported deaths in >200 countries [1]. Social media platforms, particularly Twitter, have emerged as valuable sources of information for understanding and predicting disease outbreaks. Text mining techniques allow for the extraction of relevant health information from user-generated content on social media platforms. Twitter, in particular, provides researchers with vast amounts of real-time data, enabling early response strategies and enhancing situational awareness. Analyzing Twitter data has become a crucial area of focus in medical informatics research [2,3].

COVID-19 emerged as a prominent and sustained topic on Twitter starting from January 2020, and its discussion has persisted uninterrupted up to the present day [4]. With quarantine measures implemented worldwide, individuals increasingly relied on social media to access news and express their opinions. Twitter data offer valuable insights into public discussions, sentiments, and real-time updates during global pandemics [2,5]. Using Twitter as a data source enables infodemiology studies, providing health authorities with opinions and concerns to inform their responses [6].

Since the outset of the COVID-19 outbreak, an escalating number of studies have been harnessing Twitter data to delve into the public's reactions and discussions surrounding the COVID-19 pandemic. In their respective studies, researchers used distinct methodologies to explore COVID-19–related discussions and sentiments. For instance, Xue et al [4,7] used latent Dirichlet allocation (LDA) for topic identification. Similarly, a study by Alharbi and Alkhateeb [8] investigated the sentiment of the Arabic public on Twitter, using natural language processing (NLP) and machine learning techniques, finding that the long short-term memory model outperformed the naive Bayes model with an accuracy rate of 99% [8]. Another study focused on Arabic sentiment analysis for vaccine-related COVID-19 tweets, introducing the first and largest human-annotated dataset in Arabic for this purpose; it used advanced models such as the stacked gated recurrent unit and AraBERT, achieving a 7% accuracy enhancement [9]. During the COVID-19 pandemic, a separate study analyzed online learning–related tweets in Arabic, using various classification algorithms and achieving a maximum accuracy of approximately 89.6% using the Support Vector Machine classifier to analyze public perceptions of the coronavirus [10].

In addition, research conducted in Saudi Arabia showed a significant increase in negative sentiments during the COVID-19 pandemic, with deep learning algorithms achieving high accuracy rates [11]. Other studies explored sentiment differences between countries and in response to events, using topic modeling and sentiment analysis to reveal previously unreported patterns [12]. Furthermore, a study from Morocco compared different machine learning algorithms for tweet classification, finding logistic regression to yield the best sentiment predictions [13].

Recent advancements in NLP have shown significant potential in transforming various aspects of health care, including clinical decision support, patient management, and automated analysis of health records. Recent studies, such as the one by Tamang et al [14], highlight the use of NLP for optimizing patient outcome predictions and identifying disease patterns through electronic health record data. Similarly, a study by Elbattah et al [15] explores the role of NLP in extracting actionable insights from unstructured medical texts, further underscoring the growing relevance of NLP in enhancing the health care decision-making processes.

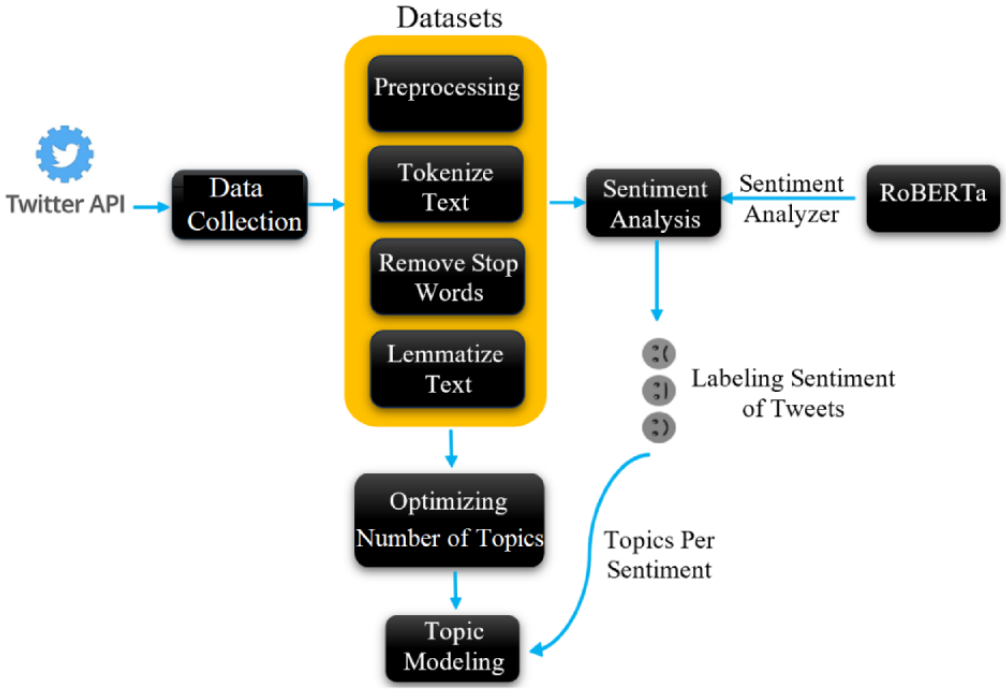
COVID-19 remains a scientifically and medically novel disease that requires in-depth and consistent research. Leveraging social media data, particularly from platforms such as Twitter, is essential for syndromic surveillance and understanding public health–related concerns. Twitter, as a prominent communication modality during disease outbreaks, offers valuable insights into public awareness and provides real-time reflections of public sentiment. Despite extensive research on COVID-19, limited studies have used social media data, specifically Twitter, to address conclusive themes and sentiment analysis in Arab regions during the early stages of the COVID-19 pandemic.

While numerous studies have investigated similar themes in different languages and contexts, there remains a notable gap in the analysis of Arabic tweets [16-22]. The Arabic-speaking population plays a significant role in the global discourse on COVID-19, and their perspectives and sentiments warrant dedicated exploration. Building on previous research, and to bridge this gap, our study used a combination of topic modeling techniques, specifically LDA, and sentiment analysis methods to uncover the predominant topics of discussion and the prevailing emotional tones within this corpus.

This Study

This study aims to analyze Twitter posts during the early stages of the COVID-19 pandemic in Arab regions to provide valuable insights into public sentiment, concerns, and awareness regarding COVID-19 in Arab communities. To achieve this, >1 million tweets posted between March 1 and March 31, 2020, were collected and analyzed. Through this analysis, we hope to assist policy makers in making informed decisions, enhancing public health communication, and implementing effective interventions to mitigate the impact of future outbreaks.

XSL•FO
RenderX



Although this study was conducted during the COVID-19 pandemic, its scope extends beyond the immediate implications of the COVID-19 pandemic. The primary goal of this research is to enhance health care planning and resource allocation in Jordan, which remains a critical issue regardless of pandemic conditions. The findings are designed to inform strategies that could be beneficial in various health care scenarios, whether in routine health care management or in response to other emergent public health challenges. Therefore, the study's relevance persists even in a postpandemic context, making it valuable for long-term health care system improvements.

Methods

Research Design

This study uses LDA for topic modeling and a sentiment analysis emotion detection tool to uncover topics and emotions in Twitter data related to COVID-19 in the Arab region. The methodological flowchart is depicted in Figure 1. Our approach to mining Twitter data adheres to the following 4 primary steps: data collection, data preprocessing, sentiment analysis, and topic modeling. The flowchart in Figure 1 illustrates how these steps are interconnected and carried out in our data analysis pipeline. Through these methods, we aim to gain valuable insights into the topics of discussion and the emotional responses of individuals in the Arab region concerning the COVID-19 pandemic.

Figure 1. Twitter data mining pipeline. API: application programming interface.

Data Collection

In our research, we harnessed the GeoCoV19 dataset, a multilingual COVID-19 Twitter dataset that spans a significant period of 90 days, from February 1, 2020, to May 1, 2020. This extensive dataset comprises hundreds of millions of tweets and is enriched with a diverse set of multilingual hashtags and keywords to ensure its comprehensiveness [23]. The dataset primarily provides tweet IDs, which presented us with the task of retrieving the actual tweet text associated with these IDs. To accomplish this, we made effective use of the Twarc application programming interface (API), a robust and efficient tool explicitly designed for this purpose [24]. The Twarc library was chosen due to its robustness in handling large-scale data collection, effective management of Twitter's API rate limits, seamless integration with existing data pipelines, and support for extended tweet metadata, making it an ideal tool for ensuring the integrity and completeness of the dataset required for this study. The Twarc API streamlined the process of collecting tweet texts corresponding to the tweet IDs provided. As we gathered all the tweets, we applied a language filter to focus exclusively on Arabic tweets. This selective filtering step was crucial for tailoring the dataset to our specific analysis, concentrating on tweets in the Arabic language.

Data Preprocessing

Data preprocessing plays a pivotal role in text mining, and it serves as a fundamental step in this domain. The purpose of this preprocessing is 2-fold: it optimizes the efficiency of prediction algorithms by eliminating potentially detrimental words, and it conserves storage space, contributing to improved computational performance [25]. In our analysis, we worked with Arabic text data, which requires thorough preprocessing to filter out any noise or irrelevant elements. The initial raw Arabic text underwent a series of transformations as part of this preprocessing effort. These transformations involved tokenization and the removal of various elements such as white spaces, punctuation marks, special characters, emojis, and URLs.

XSL•FO
RenderX

To accomplish this, we used a set of established methods for Arabic text preprocessing, including the use of Farasa [26]. Farasa proved invaluable in normalizing Arabic characters, stripping away diacritics, erasing punctuation marks, and eliminating repetitive characters, collectively enhancing the quality and relevance of the text data for our analysis.

Sentiment Analysis

Overview

To classify the primary sentiments expressed in Twitter messages, such as fear and joy, we used sentiment analysis, an NLP technique [27]. Our approach involved deploying the RoBERTa-base model, meticulously trained on a vast corpus of approximately 58 million tweets and further fine-tuned for precise emotion recognition leveraging the TweetEval benchmark [28]. This specific model, known as Twitter-RoBERTa-Base-Emotion [29], has been purposefully tailored for the nuanced task of emotion recognition within Twitter text data. It adeptly classifies text into various emotion categories, including joy, sadness, anger, fear, surprise, disgust, anticipation, and trust. Our sentiment analysis process unfolded in a sequence of four distinct steps, described in the following sections.

Step 1: Translation to English

As a reliable Arabic emotion detection API was not readily available, we initiated the process by translating Arabic tweets to English. To accomplish this, we leveraged the Google Translation API. We established an account and procured the necessary translation service. It is worth noting that the cost associated with using the Google Translation API amounts to US $20 per 1 million characters. Given that we were dealing with a substantial volume of data, encompassing 5.1 million Arabic tweets with a staggering 970,801,329 characters, the estimated cost tallied up to US $19,420. Consequently, we opted to translate 1 entire month of tweets. March was selected as the ideal candidate for translation, primarily due to its status as the month with the highest tweet volume. In addition, March witnessed several pivotal events, including Trump's declaration of COVID-19 as a national emergency, the implementation of travel bans on non-US citizens traveling from Europe, and the World Health Organization's formal declaration of the coronavirus as a global pandemic. To verify the quality of the translations, a sample of 5000 tweets was randomly selected and evaluated both before and after translation. Bilingual experts reviewed these tweets, comparing the original Arabic content with the translated English text. This review process focused on ensuring that the translations accurately conveyed the original meaning, context, and sentiment. On the basis of their feedback, we confirmed that the translations were of high quality, making them suitable for further analysis.

Step 2: English Text Preprocessing

Once the translation was complete, we embarked on preprocessing the English text. This entailed removing common stop words such as "and," "the," and "to."

Step 3: Stemming

To further refine the text data, we applied a stemming process, which involves eliminating predefined prefixes and suffixes. This step aids in reducing words to their root form. For instance, it transforms "running" into "run" through stemming.

Step 4: Emotion Determination

The final step involved determining the emotion expressed in the tweets using Twitter-RoBERTa-Base-Emotion.

Table 1 illustrates the distribution of emotions across the analyzed tweets, providing valuable insights into the prevailing sentiments during the specified time frame.

Table 1. Number of tweets per emotion.

Emotion	Tweets, n
Anger	182,105
Disgust	150,022
Joy	141,446
Anticipation	60,449
Sadness	44,591
Surprise	30,666
Fear	28,439

Topic Modeling Using LDA

In our analysis, we harnessed the power of LDA as a formidable tool for uncovering latent topics within our extensive dataset. LDA, a generative probabilistic model, proves exceptionally useful for extracting these hidden themes from a vast collection of documents. Its underlying mechanism involves representing documents as random combinations of latent topics and characterizing each topic as a distribution of words [30]. This framework of the LDA model adheres to a 3-level Bayesian approach to effectively capture the generative process. However, before delving into the application of LDA or any other probabilistic topic modeling techniques, a critical step is to determine and define the number of topics often denoted as "k" [31]. This crucial decision significantly impacts the outcomes of the topic modeling process.

Qualitative Analysis

To strengthen the reliability of our findings obtained through the LDA model, we integrated a qualitative method focused on gaining a more profound insight into the identified themes. In particular, we followed the established 6-step thematic analysis

XSL•FO
RenderX

framework outlined by Braun and Clarke [32] and successfully used by Xue et al [33]. This framework includes the following steps: (1) familiarizing ourselves with the keyword data and reviewing the most representative tweets for each topic, (2) generating initial codes to summarize key themes, (3) searching for thematic patterns by grouping similar topics, (4) reviewing and refining these potential themes to ensure coherence and consistency, (5) defining and naming themes based on their overall significance and contribution to the research question, and (6) reporting and documenting the final themes. This process was iterative and reflexive, involving multiple rounds of discussion and reassessment. Two researchers with extensive experience in social media analysis and public health independently reviewed and documented the initial codes. These codes were then examined by 2 additional researchers to refine the themes, ensuring that they accurately captured the essence of the topics.

Ethical Considerations

This study analyzed publicly available data collected from Twitter. The dataset consisted of tweet IDs, and no personally identifiable information was included in the analysis. All tweet texts were retrieved in compliance with Twitter's terms of service. Ethics approval was not sought, as the study used publicly accessible data, ensuring that no identifiable personal information was involved. To maintain the highest ethical standards, all results are presented in aggregate, guaranteeing the anonymity and privacy of individuals represented in the dataset.

Results

Descriptive Results

A total of 637,718 tweets were included in the final dataset after processing raw data. The analysis focused on identifying the most frequently tweeted bigrams (pairs of words) related to COVID-19. Bigrams are 2 consecutive words, regardless of their grammar structure or semantic meaning. They may not be self-explanatory, as in the case of the bigram "social distancing," which does not convey the meaning of either word on its own. Such an approach was adopted by Xue et al [4], and it was proved that bigrams can be a useful way to identify the most prominent topics and themes in Twitter conversations. The identified bigrams included pairs of words such as "virus corona," "stay home," "home order," "travel curfew," "new coronavirus," "spread virus," "home quarantine," "health quarantine," "coronavirus pandemic," "new infected," and "new case." Among the popular unigrams were words such as "coronavirus," "virus," "home," "new," "health," "world," "visit," "pandemic," "stay," "case," "quarantine," and "curfew." Most common unigrams and bigrams related to COVID-19, and pertinent details are listed in Table 2 (original Arabic tweets are provided in Multimedia Appendix 1).

COVID-19–Related Topics

In our study, we used the LDA technique to identify and categorize frequently co-occurring words associated with COVID-19. The LDA algorithm allowed us to manually determine the number of topics we wanted to generate. In this study, we used 2 widely recognized metrics, CaoJuan2009 and Deveaud2014, available through the R package (R Foundation for Statistical Computing), to determine the optimal number of topics for our dataset. These metrics provided a robust framework for evaluating the coherence and distinctiveness of the topics, ensuring that the final model best captured the underlying structure of the data. The CaoJuan2009 measure is minimized when the number of topics aligns with the data's intrinsic structure, while the Deveaud2014 measure is maximized to indicate topic coherence and separation. These metrics were used to assess and validate the number of topics to ensure they reflect the data's diversity and relevance. By leveraging these 2 complementary metrics, we ensured that the selected number of topics provided meaningful insights and reduced the risk of overfitting. The number of topics was determined when these metrics stabilized, indicating a consistent result.

Upon evaluating the metrics, it was found that the CaoJuan2009 score converged at its minimum value with 16 topics, while the Deveaud2014 score peaked at its maximum value with the same number of topics. On the basis of this, we concluded that the optimal number of topics, denoted as "k," is 16, as shown in Figure 2.

In addition, we calculated the topic distance and visualized the intertopic relationships using a 2D plane [34]. Each circle in the plot represents a distinct topic, ranging from topic 1 to topic k. The positioning of these circles reflects the calculated distances between topics, offering a visual representation of their relationships.

It is also worth noting that cross-validation is less commonly applied in topic modeling for several reasons. These include computational challenges associated with applying cross-validation to unsupervised models, the interpretive nature of topic models, and the emphasis on qualitative coherence over predictive performance. Most studies on LDA and related techniques do not apply cross-validation, as the focus of topic modeling is on the interpretability and coherence of the topics rather than on predictive performance. Instead, topic models are typically evaluated using internal coherence and stability measures, such as the CaoJuan2009 and Deveaud2014 metrics, which prioritize the coherence of the topics and the consistency of the results across multiple runs. This approach is consistent with what is found in most related work on LDA. For example, Blei et al [30] introduced LDA and highlighted that the evaluation of topic models is traditionally done using measures such as coherence scores.

In Table 3 (original Arabic tweets are provided in Multimedia Appendix 2), we present the findings of the 16 LDA topics, revealing the most frequently occurring words within each topic along with the percentage of tweets falling under each respective topic. Among all 16 topics, topic 5 stands out with the highest percentage (9.98%) of tweets associated with it. In topic 5, we observed a significant co-occurrence of specific words, including "coronavirus," "increase," "health," "new," "infected," "death," "recovery," and "case." This combination of words indicates an escalation in the number of COVID-19 infections, leading to unfortunate fatalities and the emergence of new cases. Moreover, the presence of the term "recovery" implies that some individuals who were previously infected are now undergoing healing and improvement. Furthermore, we

XSL•FO
RenderX

calculated the topic distance and illustrated the intertopic distance [35] in a 2D plane, as depicted in Figure 3. Each circle on the plot corresponds to a topic, ranging from topic 1 to topic 16 in this study. The positions of these circles were determined based on the calculated distances between the topics. Notably, in the visualization, the circles were not overlapping, which served as a validation of the 16 topics.

Figure 2. Metrics for estimating the optimal number of topics, ranging from 2 to 25 topics.

COVID-19–Related Themes

Through the process of thematic analysis, we were able to categorize the identified topics, bigrams, and representative tweet samples into distinct themes, as shown in Table 4 (original Arabic tweets are provided in Multimedia Appendix 3).

The sample tweets provided in Table 4 are excerpts taken from the original tweets. These 16 topics have been categorized into eight overarching themes, summarized below.

1. Preventive measures and safety (“public health measures”): this theme focuses on various measures to prevent the spread of COVID-19, such as wearing masks, washing hands, using sanitizers, and practicing social distancing.
2. Medical and health care aspects: this theme encompasses topics related to the medical and health care aspects of COVID-19, including hospitals, doctors, treatments, testing, and recovery.
3. Government and social measures: this theme covers government actions, social measures, and policies implemented to address the COVID-19 pandemic, including lockdowns, travel restrictions, home orders, suspending schools, avoiding gatherings, closing shops, staying at home, and support measures.
4. Impact and numbers: this theme involves discussions about the impact of COVID-19, including the number of cases, deaths, recoveries, and updates on the situation.
5. Vaccine development and research: this theme revolves around vaccine development, clinical trials, and scientific research related to finding a solution to COVID-19.
6. COVID-19 and religious practices: this topic discusses how COVID-19 has impacted religious practices and gatherings. It mentions places of worship ( ) and the importance of adhering to prayers ( ) and religious guidelines ( ) during the COVID-19 pandemic, especially during occasions such as Ramadan ( ). The theme also includes expressions of gratitude and good wishes for nations and people (, ,).
7. Global impact of COVID-19 on sports and countries: this topic discusses the spread of COVID-19 in different countries, including China, Italy, and the United States, and its impact on various aspects, such as sports events and leagues in Europe and the Middle East. It also mentions the virus as a global pandemic and its effects on athletes and players ( ) as well as its presence in different regions around the world.
8. COVID-19 and national efforts: this theme focuses on the efforts of different nations, including Saudi Arabia and Kuwait, in combating COVID-19. It mentions leaders (, ,) and their efforts to protect the health and well-being of their citizens (,). The theme includes expressions of gratitude for the nation’s efforts in managing the COVID-19 pandemic ( ) and highlights the importance of public health ( ). Textbox 1 provides a comprehensive list of topics, thoughtfully translated into English for better clarity and accessibility.

Table 4. Themes based on topic classification, bigrams, and sample tweets.

Theme and topic	Bigrams	Sample tweets
Preventive measures and safety		
Face mask	Wear mask	A note for your safety from the new coronavirus infection: Avoid social gatherings with more than 1 person. Avoid crowded areas or places where you might interact with individuals who are sick. Avoid handshakes as they are among the primary causes of virus transmission. Wear a mask whenever possible.
Hands	Wash hands, use sanitizers	Avoid gatherings, closed spaces, and crowded areas, along with regularly washing your hands with water and soap or sanitizing them with alcohol-based disinfectants. By God's will, you will be protected from contracting the new coronavirus.
Social distancing	Social distancing	Social distancing means staying away from gatherings and crowded places. If you must leave your home, maintain a distance of at least 2 meters from the people around you. Source: Cleveland Clinic, COVID-19.
Medical and health care aspects		
Health authorities	Precautionary measures, followed the instructions	Home quarantine protects against the risk of a person spreading the coronavirus without showing symptoms, making them a potential source of transmission to various groups. Preventive measures against COVID-19 ease the burden on health care providers, enabling them to fulfill their roles in treating other illnesses and performing preventive tasks, including COVID-19 detection. Voice of the physician.
Recovery	Case recovery	Breaking: The Ministry of Health announces the recovery of the first coronavirus case in the kingdom. This concerns the young man who returned from Italy and was previously announced as the first imported case of the virus in Morocco. COVID-19, Morocco, Recovery, Ministry of Health.
Treatment	Treating the infected	The Minister of Health announces the initiation of treating patients with COVID-19 with the chloroquine vaccine.
Treatment	New drug	The *Washington Post* reports that Chinese experts and physicians have successfully fought COVID-19 using chloroquine, a drug primarily used to treat malaria, and Kaletra, an HIV medication that combines lopinavir and ritonavir. Emirati physician Omar Al Hammadi shares the success of this trial.
Hospital	Field hospital	Starting Sunday, a physician will accompany every ambulance, and a field hospital will be established inside the trade unions complex. Dr Ali Al-Abous, President of the Jordanian Medical Association, comments on the nationwide curfew in Jordan due to the COVID-19 pandemic.
Government and social measures		
Lockdowns and suspending	Closing shops, suspending schools	Precautionary measures in Kuwait against COVID-19: suspension of studies and work, cancellation of weddings, closure of mosques, closure of malls, closure of salons, partial curfew, extension of the suspension of studies, regulation of work in central markets, closure of shops, postponement of installments.
Travel restrictions	Travel ban	Saudi Arabia: Saudi Arabia suspended studies, banned cafes and shisha, prohibited sports gatherings and cinemas, halted entertainment activities, stopped Umrah and travel, and conducted intensive testing to search for patients. All for your benefit—help your government overcome these circumstances with minimal losses.
Home orders	Stay home	Stay home and protect your family from coronavirus. Prevention guidelines. Stay home.
Curfew	Curfew	Breaking: Al Jazeera correspondent reports the sounding of alarm sirens across Jordan as the nationwide curfew begins to combat the spread of COVID-19.
Remote	Remote work	It is everyone's duty to follow the precautionary measures taken by our government, may God protect them, to prevent the spread of COVID-19. At our facility, we have informed the success team to work remotely from their homes until further notice.
Impact and numbers		
New cases	Confirmed cases, increase in cases	The Kuwaiti Ministry of Health has reported new cases of the novel coronavirus, and the total number of patients that have exited quarantine is 20.
Deaths	Coronavirus deaths	A new death has been recorded in Jordan due to COVID-19, bringing the total number of deaths to 5.
Vaccine development and research		
Religious guidelines	Prayer, supplication	Breaking: The Senior Scholars Authority calls on everyone to adhere to the instructions, guidelines, and regulations, to fear God, and to resort to prayer and supplication. COVID-19, Saudi Arabia.

XSL•FO
RenderX

Theme and topic	Bigrams	Sample tweets
Umrah	Suspension of Umrah	It was discovered during the COVID-19 crisis that preserving life is one of the most important objectives of Sharia, and everything is subordinated to it. The suspension of Umrah and prayer in mosques reflects the greatness of Islam and the depth of Sharia's objectives.
Global impact of COVID-19 on sports and countries		
Postponement of matches	Postponement of matches	The Union of European Football Association has decided to postpone all matches scheduled for next week. Sports, COVID-19.
Italy	The situation in Italy	Terrifying numbers in Italy and Iran; a video shows the spread of the coronavirus outside China until March.
COVID-19 and national efforts		
King Salman	Royal support	King Salman bin Abdulaziz and Crown Prince Mohammed bin Salman. The Saudi Arabian Monetary Authority announces support for the private sector with 1 billion Saudi riyals to face the expected financial and economic impacts of the coronavirus.
Thanks	Government gratitude	We thank God for the blessing of Islam and the blessing of Salman. Every Saudi has the right to be proud and boast about Saudi Arabia. May God protect its government and people from all harm. Saudi Arabia. COVID-19. Stay at home.

Sentiment Analysis

We conducted sentiment analysis for each of the 16 topics and presented the results in Figure 4 and Table 5. Figure 4 visualized 7 emotions: anger, disgust, joy, anticipation, sadness, surprise, and fear. Across all 16 topics, anger (represented by the red line) was the dominant emotion in 16 topics, followed by disgust (green line), joy (blue line), and anticipation (orange line). To delve deeper into the emotional aspects of the data, we provide a breakdown of the number of tweets associated with each emotion across different topics in Table 5. For example, in topic 5, a substantial number of tweets (n=17,848) expressed anger, reflecting a strong sentiment regarding the need for essential measures and precautions. This high prevalence of anger in topic 5 stands out in comparison to the other topics. It is worth noting that excessive anger, if left unmanaged, can lead to a range of medical problems. Managing emotions such as anger is crucial not only for mental well-being but also for overall physical health.

Figure 4. Sentiment analysis for each of the 16 latent topics.

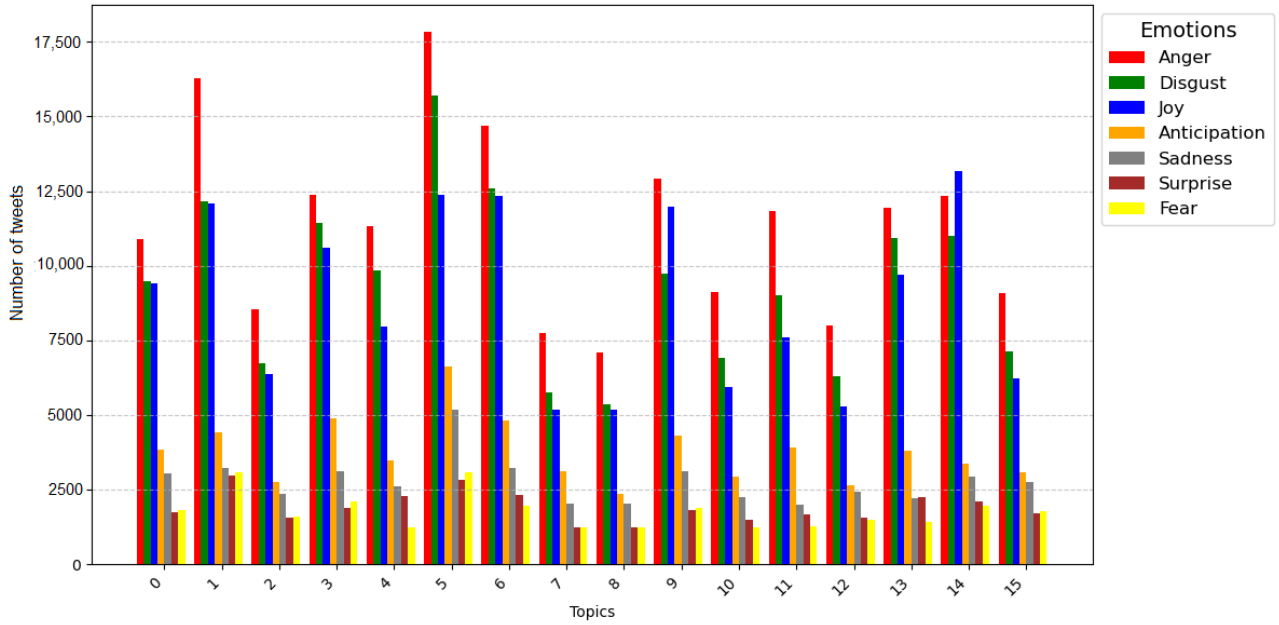

Table 5. The number of tweets for 7 emotions across 16 topics.

Topic	Anger	Anticipation	Disgust	Fear	Joy	Sadness	Surprise
0	10,896	3834	9475	1835	9428	3040	1757
1	16,295	4434	12,164	3079	12,083	3217	2965
2	8559	2772	6729	1585	6366	2346	1554
3	12,391	4894	11,424	2110	10,602	3113	1876

Discussion

Principal Findings

This study delved into public discussion and emotional expressions related to COVID-19 using Arabic Twitter messages. Twitter users engaged in discussions encompassing 8 primary themes regarding COVID-19. Using topic modeling on the tweets proved valuable in uncovering insights into COVID-19–related topics and concerns. The outcomes highlighted several crucial observations.

This analysis concentrates on tweets from March 2020, a pivotal phase in the COVID-19 pandemic's unfolding narrative. During this period, the second stage of the COVID-19 pandemic emerged prominently, marked by a significant milestone as Arabic countries reported their initial cases of COVID-19. Subsequently, a cascade of vital health measures ensued, encompassing the enforcement of quarantine protocols, the temporary cessation of air travel, and the inevitable postponement or cancelation of various events. This time frame aligns logically with the peak frequency of tweets, as previously observed by Taneja et al [22] and Haouari et al [34].

Amidst the array of all 16 topics, a discernible pattern surfaced, characterized by the recurring presence of specific keywords such as "coronavirus," "increase," "health," "new," "infected," "death," "recovery," and "case." This linguistic cluster strongly implies a surge in COVID-19 infections, accompanied by lamentable loss of life and the emergence of new cases during the ongoing COVID-19 pandemic. It is imperative to emphasize that our chosen time frame aligns precisely with the onset of the COVID-19 pandemic's second phase, coinciding with heightened global concern. The substantial spike in COVID-19 cases in Italy during this period ignited a profound sense of alarm on a global scale. This surge in worldwide apprehension may have contributed to the observed increase in tweet frequency, corroborating findings from multiple studies [22,34].

Furthermore, substantial discussions revolving around the COVID-19 pandemic within diverse Arabic nations have drawn significant interest. These conversations are marked by a prevailing sense of indignation. Moreover, public sentiments concerning the spread of COVID-19 unveiled an underlying sense of anticipation toward prospective measures. These sentiments were accompanied by a mix of emotions, including anger and fear; a notable undercurrent of fear was predominant in discussions revolving around the COVID-19 crisis and the resulting fatalities. This trend aligns with global sentiments, as documented by Lwin et al [36], wherein public emotions underwent a noticeable shift from fear to anger throughout the COVID-19 pandemic, with traces of sadness and joy also emerging.

Noteworthy, the appearance of dialogues concerning COVID-19 and religious practices introduced a fresh subject not previously detected in prior research. This indicates a developing connection between COVID-19 and religious matters on the Twitter platform. This is particularly apparent due to the substantial influence of religious identity on attitudes and actions concerning the COVID-19 pandemic and vaccination efforts; the COVID-19 pandemic has significantly reshaped communal worship and gatherings as measures to curb the virus's transmission [37]. Furthermore, religious leaders have assumed a central role in championing COVID-19 vaccination campaigns, effectively addressing and mitigating vaccine hesitancy [38].

In-Depth Analysis of Findings

The application of topic modeling and sentiment analysis in this study provided several valuable insights into public sentiment and thematic discussions during the early stages of the COVID-19 pandemic in Arab regions. The findings largely align with anticipated outcomes, such as the focus on preventive measures and safety and medical and health care aspects, both of which were expected topics given the nature of the COVID-19 pandemic.

However, the emergence of discussions on COVID-19 and religious practices was a unique finding that adds depth to the understanding of public discourse in Arab communities. This theme highlights the intersection of the COVID-19 pandemic with cultural and religious practices, which had not been as thoroughly explored in previous research. It underscores the significant impact that COVID-19 had on religious identity, communal worship, and adherence to religious guidelines during pivotal periods such as Ramadan.

Another notable aspect was the attention given to the global impact of COVID-19 on sports and countries, reflecting the broad international concern and how global events, especially sports, were affected. This indicates that the COVID-19 pandemic's influence went beyond public health and extended into societal and cultural dimensions, impacting activities that are deeply integrated into daily life.

In addition, the sentiment analysis revealed a nuanced distribution of emotions, with a significant proportion of tweets expressing anger and disgust, as expected, given the uncertainty surrounding the COVID-19 pandemic. However, there was also a notable presence of positive emotions, such as hope and solidarity, particularly in tweets discussing community support and coping mechanisms. This suggests that, despite the overwhelming nature of the crisis, many users turned to social media not only to express negative emotions but also to share supportive messages and encourage others.

Overall, the identified themes and their respective discussions provide a comprehensive view of public sentiment, concerns, and priorities during the early COVID-19 pandemic period. These insights not only reflect the immediate response to the health crisis but also highlight the diverse and context-specific aspects that shaped public discourse. Such findings offer a foundation for more effective public health communication and intervention strategies, particularly in culturally sensitive contexts.

Strengths

This study provided valuable insights into the sentiments and concerns of Arabic-speaking Twitter users during the COVID-19 pandemic, underscoring the significance of social media as a means of understanding and addressing public health issues in the digital era. First, the analysis encompassed a substantial

XSL•FO
RenderX

dataset of 1 million Arabic tweets, offering a comprehensive view of the sentiments and topics expressed by Twitter users in Arabic-speaking countries during a specific period of the COVID-19 pandemic. Besides, the study used a combination of machine learning techniques, including topic modeling and sentiment analysis, to uncover and categorize themes and emotions within the dataset, providing a holistic understanding of the data. By identifying and categorizing 16 conversation topics into 8 themes, the study offered a structured view of the discussions surrounding COVID-19 in the Arab region, making it easier to interpret and use the findings. Finally, the inclusion of emotion analysis adds depth to the study, revealing how Twitter users in the Arab world emotionally responded to various aspects of the COVID-19 pandemic.

Limitations

First, at the forefront of our approach, we meticulously aimed to unravel the complexities embedded within the COVID-19 pandemic's second phase. Our focus was sharp and exclusive, centered on harnessing tweets originating exclusively from March 2020. The motivation behind this specific time frame stemmed from our intention to subject translated tweets to a comprehensive sentiment analysis. This intricate process relied upon the Google API translation service, which, although effective, is accompanied by a substantial cost factor. The financial implication associated with translating the entirety of the datasets using this service was a noteworthy consideration that prompted us to make strategic choices in our analysis approach.

Second, it is crucial to recognize that Arabic is a linguistically intricate language characterized by a rich array of dialects and intricate cultural nuances. These unique linguistic qualities can present substantial challenges for automated sentiment analysis tools. While we attempted to apply automated sentiment analysis to Arabic tweets, we encountered difficulties in precisely capturing the subtleties of emotions. Automated tools often grappled with interpreting nuanced sentiments, such as sarcasm, irony, and contextual shifts in sentiment that frequently permeate social media conversations.

Third, a strategic decision was made to exclude non-Arabic tweets from our analyses. As a result, our findings were inherently confined to users who exclusively communicated in Arabic. It is essential to underscore that the fundamental objective of our research revolves around gaining insights into the opinions and reactions of Arabic countries in relation to COVID-19.

Furthermore, while our study leveraged social media data as a proxy for public sentiment, it is essential to recognize the inherent biases associated with using Twitter data. For instance, social media users may not be representative of the general population, as certain demographics might be underrepresented on platforms such as Twitter. A study by Padilla et al [39] has shown that social media content can be biased based on whether individuals are local residents or visitors and the types of activities they engage in throughout the day. Similarly, Gore et al [40] highlighted that the sentiment of tweets is often correlated with the geographical area in which they were composed, suggesting that local context and specific events may have a significant impact on sentiment analysis results. Frank et al [41] also found that emotional expressions, such as happiness, vary significantly by location, further reinforcing the influence of geographic factors on sentiment.

In addition, it is plausible that individual personality traits or political affiliations, as suggested by Auer and Elena [42], could influence whether a user expresses positive or negative sentiments. This raises an open question about the extent to which sentiment reflects variance in psychological traits versus the situational context in which those traits are expressed. These factors could contribute to biases in our dataset and should be considered as potential sources of influence on the study's outcomes.

Future Work

Regarding future studies focusing on COVID-19, first, there arises a noteworthy avenue for exploration comparing the sentiments and opinions of Arabic-speaking populations with those of individuals expressing themselves in other languages. A comprehensive approach might encompass languages such as English, Italian, French, German, and Spanish. Such comparative analyses have the potential to yield valuable insights into the cross-linguistic dynamics of perceptions and responses to the COVID-19 pandemic.

Second, another promising avenue for future research involves conducting a comparative analysis between sentiment analysis using human-labeled data and automated tools specifically tailored for Arabic languages. This comparative study should aim to ascertain the feasibility of leveraging these automated tools as an alternative to translation APIs. By meticulously comparing the results obtained from human-labeled sentiment analysis and those generated by automated tools, researchers can gauge the efficacy, accuracy, and reliability of automated sentiment analysis for Arabic tweets. The outcomes of this research hold the potential for far-reaching implications, potentially presenting a cost-effective and streamlined avenue for sentiment analysis that eliminates the reliance on costly translation APIs.

By providing an accurate and efficient mechanism for measuring sentiments in Arabic tweets, researchers and mental health professionals could identify patterns of emotional distress or psychological well-being. This could be especially pertinent during times of crises, enabling timely interventions and support for individuals experiencing heightened emotional responses. Importantly, the ability to effectively harness sentiment analysis for understanding emotional states has the potential to empower the broader field of mental health research and intervention as well as enhance our understanding of collective emotional dynamics within Arabic-speaking communities.

Third, there is an imminent need for research to unravel the stem of fabricated tweets that emerge during a pandemic. Given that Twitter users experience a heightened sense of fear, which might be exacerbated by the proliferation of misinformation, it becomes a critical endeavor to investigate the prevalence and impact of false tweets. Subsequent studies could significantly benefit from spotlighting the issue of misinformation, with a specific focus on understanding how government officials and

XSL•FO
RenderX

international organizations can effectively manage the dissemination of deceptive messages targeting the public. By comprehensively addressing the challenges posed by misleading content, we can enhance our collective understanding of navigating information dissemination during such critical periods.

Conclusions

This study delves deep into the intricate web of topics and emotions found in Arabic tweets about COVID-19. It highlights how platforms such as Twitter, especially during times of global change, are crucial for capturing the diverse feelings and concerns of Arabic speakers. Through a mix of topic modeling and sentiment analysis, we revealed the basic human emotions in user responses to COVID-19 tweets from March 2020.

We used 2 methods together: topic modeling (specifically LDA) and sentiment analysis tools. These helped us uncover the main themes and feelings within the tweets. Anger was the prominent emotion tied to COVID-19 topics, accompanied by other emotions. Joy was linked to vaccine and education discussions, while authority and politics stirred up anger. Sadness emerged from topics about cases, deaths, and the impacts on families and mental health.

This study connects social media, emotions, and the global scene. It sheds light on the emotional layers of digital conversations, offering insights into COVID-19–related tweets. These findings guide better communication strategies and compassionate responses, strengthening our collective resilience in the face of challenges.

Moreover, the results and workflow of this study present actionable insights for the medical and public health communities. By integrating our findings into official government documentation or public health research, authorities can tailor their communication strategies based on public concerns and emotions. This, in turn, helps in shaping more effective educational campaigns and policy interventions. Our methodology also serves as a robust tool for continuous monitoring of public sentiment in real time, allowing policy makers to stay informed and adapt their strategies accordingly. This approach ensures that responses are not only timely but also grounded in the actual sentiments and needs of the population.

Abstract

Background: The challenge of extracting meaningful patterns from the overwhelming noise of social media to guide decision-makers remains largely unresolved.

Objective: This study aimed to evaluate the application of a semantic network method for creating an interactive visualization of social media discourse surrounding the US health care system.

Methods: Building upon bibliometric approaches to conducting health studies, we repurposed the VOSviewer software program to analyze 179,193 YouTube comments about the US health care system. Using the overlay-enhanced semantic network method, we mapped the contents and structure of the commentary evoked by 53 YouTube videos uploaded in 2014 to 2023 by right-wing, left-wing, and centrist media outlets. The videos included newscasts, full-length documentaries, political satire, and stand-up comedy. We analyzed term co-occurrence network clusters, contextualized with custom-built information layers called overlays, and performed tests of the semantic network's robustness, representativeness, structural relevance, semantic accuracy, and usefulness for decision support. We examined how the comments mentioning 4 health system design concepts—universal health care, Medicare for All, single payer, and socialized medicine—were distributed across the network terms.

Results: Grounded in the textual data, the macrolevel network representation unveiled complex discussions about illness and wellness; health services; ideology and society; the politics of health care agendas and reforms, market regulation, and health insurance; the health care workforce; dental care; and wait times. We observed thematic alignment between the network terms, extracted from YouTube comments, and the videos that elicited these comments. Discussions about illness and wellness persisted across time, as well as international comparisons of costs of ambulances, specialist care, prescriptions, and appointment wait times. The international comparisons were linked to commentaries with a higher concentration of British-spelled words, underscoring the global nature of the US health care discussion, which attracted domestic and global YouTube commenters. Shortages of nurses, nurse burnout, and their contributing factors (eg, shift work, nurse-to-patient staffing ratios, and corporate greed) were covered in comments with many likes. Comments about universal health care had much higher use of ideological terms than comments about single-payer health systems.

Conclusions: YouTube users addressed issues of societal and policy relevance: social determinants of health, concerns for populations considered vulnerable, health equity, racism, health care quality, and access to essential health services. Versatile and applicable to health policy studies, the method presented and evaluated in our study supports evidence-based decision-making and contextualized understanding of diverse viewpoints. Interactive visualizations can help to uncover large-scale patterns and guide strategic use of analytical resources to perform qualitative research.

KEYWORDS

social media; semantic network; health system; health policy; ideology; VOSviewer; health care reform; health services; health care workforce; health insurance

Introduction

Background

The US health care system, characterized by high costs [1] and perceived to fall "far short of its potential" [2], has been a focal point for media attention and public commentary over the past decade. Discussions have revolved around topics such as the repeal of Obamacare, presidential health care agendas, the exorbitant costs of health care, comparisons to systems in other nations, and postpandemic health care personnel shortages. Throughout this period, conservative, moderate, and liberal media outlets have produced a variety of content, including newscasts, full-length documentaries, political satire, and stand-up comedy, all centered on the intricacies of the US health care system [3-6]. When disseminated through YouTube (Google Inc), the most popular platform among US social media users [7], select videos have generated millions of views and tens of thousands of comments. To the best of our knowledge, the perspectives of YouTube commenters on the US health care system and its reform, despite their considerable value for policy analysis, remain unexplored.

Objectives

Social media discussions are abundant, but they are often chaotic, noisy, indignant, and hateful [8-11]. There is a need for a method that effectively visualizes large volumes of commentary, filters out the noise, and highlights key patterns, making the information more digestible for stakeholders. The current state of social media research falls short of efficiently and clearly disseminating scientific outputs to diverse audiences. In quantitative social media studies, the constraints are statistical and graphical outputs with low idea density or high decoding requirements, which often require specialized knowledge. In qualitative studies, researchers communicate analytical outputs as summaries of themes and subthemes with representative quotes; however, they are based on limited data samples.

To address these challenges, we propose a mixed methods approach of mapping social media commentary. This approach combines automation and human judgment to create a visual representation of social media comments' contents and structure, presenting them as a semantic network [12]. This methodology is particularly relevant for researchers, policy makers, and the wider public seeking a better understanding of complex social media narratives. We repurpose VOSviewer (Centre for Science and Technology Studies at Leiden University), a user-friendly bibliometric tool, to analyze tens of thousands of social media comments on YouTube regarding the US health care system. In this study, semantic networks are graphical representations of social media comment meanings. Nodes represent terms frequently mentioned in YouTube comments, linked and grouped into clusters based on their co-occurrence.

Since their introduction in 2010, VOSviewer algorithms have been extensively applied to build term co-occurrence networks from the text of article titles and abstracts [13-20]. Visualization of nonbibliometric textual data as semantic networks in VOSviewer was proposed in 2011 [21], followed by early visualizations of Twitter and YouTube discussions ([22-25]). Subsequent explorations of VOSviewer's applications to social media comments and hashtags primarily led to cluster mapping ([26-35]). Notably, some scholars enhanced their cluster maps with informational layers called custom overlays to reveal patterns not visible in the base network [36-38].

Previous research compared VOSviewer semantic networks to networks generated from manually coded Twitter text [26]. However, there have been few systematic evaluations of VOSviewer-generated semantic networks derived from social media data. Consequently, our overarching goal is to evaluate VOSviewer's application to social media data: Can it produce credible semantic networks to be used as analytical and communication tools? We test VOSviewer's term co-occurrence map with custom-built overlays by posing 3 research questions:

1. How well does the VOSviewer network capture the content, context, and structure of social media comments?
2. What does it reveal about a decade-long online public discussion of the US health care system?
3. What is the policy analysis value of VOSviewer visualizations?

Methods

Semantic Network Construction

VOSviewer generates a custom semantic network by processing a corpus text file featuring social media comments. Our corpus comprised the text of primary comments and first-level replies to 53 videos shared by 17 US-based media outlets on their respective YouTube platforms between 2014 and 2023. The videos were sourced from news outlets such as Consumer News and Business Channel, Cable News Network, Fox News, and Public Broadcasting Service Frontline. Detailed criteria for video selection and video characteristics are outlined in the Tables S1 and S2 in Multimedia Appendix 1 [39]. After eliminating 5575 duplicate comments from the initial dataset of primary comments at first-level responses, our final corpus encompassed a total of 179,193 unique comments.

VOSviewer processes YouTube comments by detecting sentences, applying the Apache Software Foundation's OpenNLP library algorithm for part-of-speech tagging, identifying terms as nouns and the longest noun phrases, and unifying terms through various methods [17,18]. From an initial pool of 1948 terms appearing in at least 60 comments, a subset of 323 (16.58%) terms related to the US health care system, such as Obamacare, prescription, and wait time, was selected for the final semantic network. A detailed term selection process,

XSL•FO
RenderX

including manual screening and thesaurus construction, is described in Multimedia Appendix 1.

By distilling 179,193 comments into a network with several hundred nodes, a macro model of YouTube video commentaries was created, providing insight into social media users' discussions on US health care. In this network, terms are interconnected and organized into distinct, nonoverlapping clusters [15,19,20]. A cluster is a group of terms tightly linked within the group and loosely connected with terms outside it. If >1 term was extracted from the text of the comment, it is possible for the same comment to be represented by multiple nodes in multiple clusters. We did a thematic analysis of clusters to gain insights about the US health system discourse.

We addressed limitations observed in previously published semantic networks by enhancing the network's informational value. First, we added custom overlays to VOSviewer's map, which displays the color of network nodes based on selected attributes. To build overlays, we coded each comment to reflect the theme of its YouTube video and added these codes, along with other comment characteristics (eg, comment date), to a scores file, which was uploaded to the VOSviewer together with our corpus file that contained YouTube comments (for more information on building corpus and scores files, refer to Multimedia Appendix 1). Second, we presented findings with hyperlinks to VOSviewer Online for broader accessibility and interactive engagement with our semantic network.

Network Interpretation and Evaluation

The evaluation of the US health care system's semantic network and its overlays was structured as follows. A comparison of 2 networks, before and after the deletion of repeated comments, served as a test of network robustness. Thematic alignment between the network terms, extracted from YouTube comments, and the videos that elicited these comments was a test of network's content representation.

To examine structural relevance, we asked if network relationships reflected the underlying meanings evident in YouTube comments. We examined clusters: Do terms in the same cluster have more similar meanings than terms in different clusters? We also examined pairs and groups of interconnected terms: Are they used together in the source data? Do their relationships align with existing knowledge? A comprehensive analysis of all pairs or term groups is outside of the scope of this study. For practical reasons, we engaged in close reading of a limited number of comments, focusing mainly on smaller nodes. When the number of comments exceeded 200, we randomly sampled 200 comments to cover discussions of different videos, taking care to sample more than once when we encountered heterogeneous ideas that required careful interpretation. When ≥2 nodes were examined, we used close reading of comments that mentioned all selected terms. Following the approach by Eve [40], network visualizations were used to locate "points of interest, which are then resynthesized into close readings."

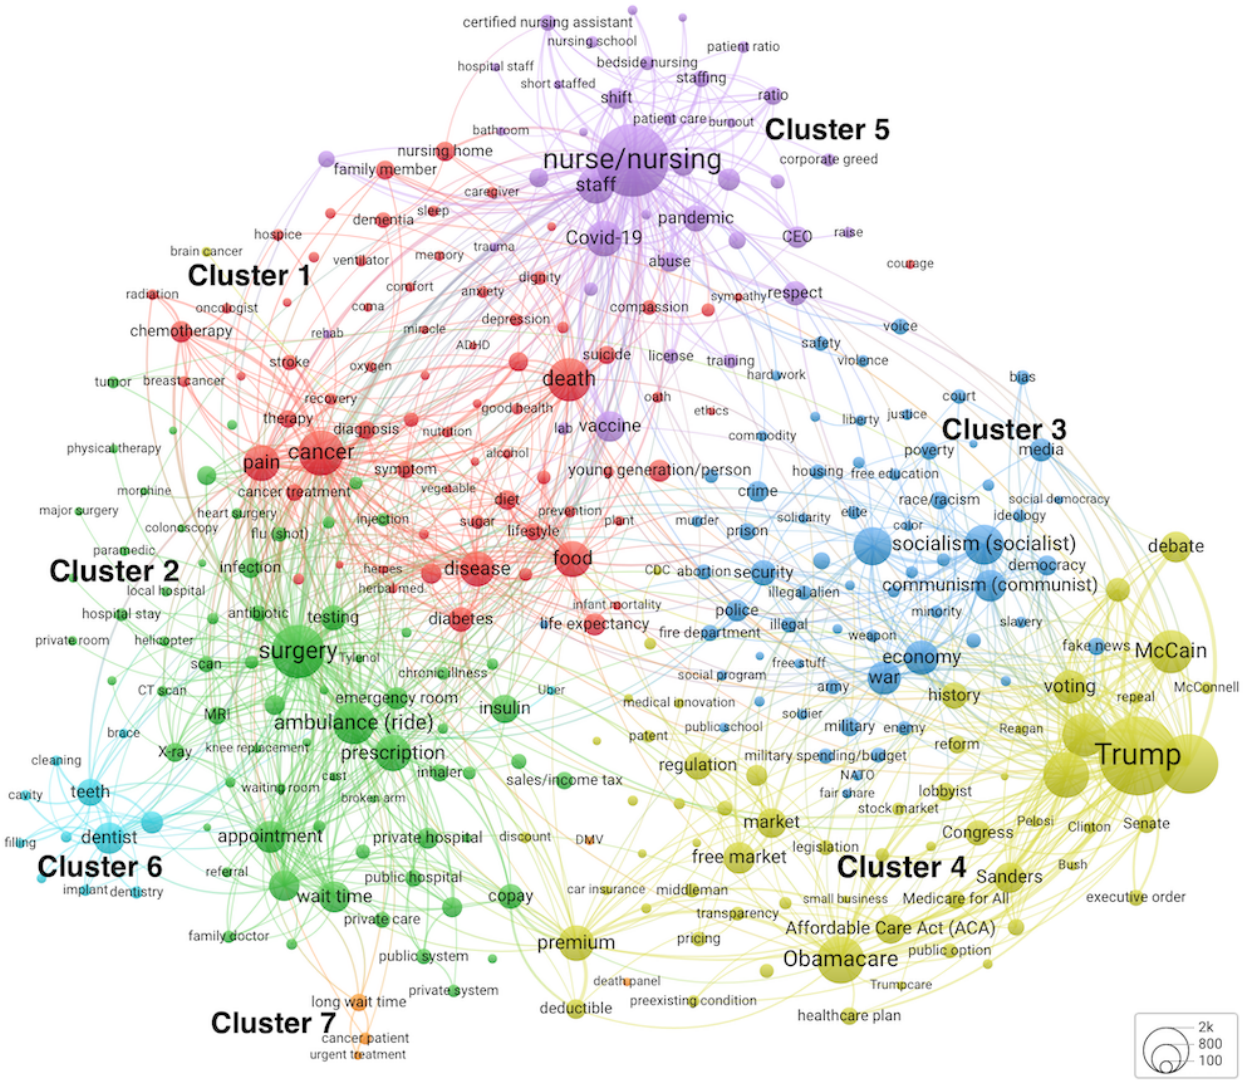
In addition, we performed tests of semantic accuracy through raw data verification. Specifically, we cross-checked ambiguous or unexpected terms in our network against the comments that mentioned them. The analysis involved multiple readings of each comment to capture nuances of how individuals articulate their experiences or opinions of the US health care system, focusing on the words that were extracted as terms, their meaning, and context. On several occasions, for example, when performing a close reading for ideology, we offered brief summaries of the main ideas expressed by the commenters. Our validation of semantic network findings against extant comments adhered to the principles for quantitative text analysis outlined by Grimmer and Stewart [41].

Finally, we tested the usefulness of semantic network analysis for generating policy-relevant insights. We picked 4 health system design concepts—universal health care, Medicare for All, single payer, and socialized medicine—and examined how the comments mentioning these concepts were distributed across the terms we mapped. For insights into the policy ramifications of public perceptions of health system design, we focused on ideological terms and those with the highest share of comments referring to each concept.

Ethical Considerations

Ethics approval for this study was sought from Central Michigan University's Institutional Review Board (project 2023-1021-Mt. P). The study did not meet the definition of human participant research under the purview of the institutional review board according to federal regulations. The study used publicly accessible user-generated YouTube comments. The data were deidentified and aggregated before analysis. As the results are presented in an aggregate form, individual commenters cannot be identified. Informed consent has not been obtained. No compensation was provided to comment contributors.

Results



A Semantic Network of Term Co-Occurrence and Clustering

From a manually screened list of 539 terms occurring in our corpus at least 60 times, VOSviewer's algorithm assisted in the selection of 323 (59.9%) most relevant terms [19]. Figure 1 [42] shows a 7-cluster solution for a term co-occurrence network.

On average, each term represented 357.74 (SD 606.88; median 163, IQR 104-321) comments. The longer the comment, the greater the likelihood that multiple terms were extracted from it. VOSviewer assigns cluster numbers based on the quantity of nodes; the same cluster numbers appear in our online interactive maps (URLs are provided in the notes of Figure 1).

XSL•FO
RenderX

Figure 1. A co-occurrence network (cluster map) of terms extracted from the comments on 53 YouTube videos about the US health care system. Binary-counted terms that occurred ≥60 times were mapped. An interactive map is available from Leiden University's VOSviewer app.

Cluster 1 (red) emerged as the largest group of nodes, covering chronic diseases, treatment, pain, and death. Its diverse terms also included topics related to disease prevention (*diet, exercise,* and *smoking*), mental health (*ADHD* [attention-deficit/hyperactivity disorder,] *anxiety*, and *depression*), and end-of-life issues (*hospice*, *euthanasia*, and *do-not-resuscitate*). Below it, cluster 2 (green) terms covered services, encompassing surgeries, emergency medical services, procedures, diagnostics, wait times, and discussions about public versus private health organizations and prescription medications. On the right, cluster 3 (dark blue) had terms about political ideologies, economic, societal, and cultural issues, surrounded by nodes from cluster 4 (yellow) related to political actors, institutions, the 2010 Patient Protection and *Affordable Care Act* (*ACA* or *Obamacare*), market regulation, and insurance terminology. The top of the map displayed a group of terms (cluster 5, purple) dedicated to health worker shortages, nurse-to-patient ratios, and nurses' burnout. Dental care terms formed a group on the lower left (cluster 6, light blue). Finally, a 5-node group (cluster 7, orange) at the bottom of the map had terms related to long wait times by patients with cancer who required urgent treatments, as well as further away terms *DMV* (Department of Motor Vehicles) and *death panel*.

The network displayed a rather coherent collection of terms, the meaning of which could be intuitively understood within the context of the US health care, with a few exceptions. For instance, as we manually selected terms for map inclusion, we checked the use of an ambiguous term *DMV* in YouTube users' comments. *DMV* was mentioned as a metaphor in a debate of government-managed health care efficiency. It was retained due to its relevance to the health care discourse.

The interpretive value of our network extended beyond a simple list of terms. The network specified links between terms that were often mentioned together, for example, *pricing* and *transparency* in cluster 4. Meaning extraction was further aided by the analysis of spatial proximity, cluster assignment, and cluster boundaries. For example, *preexisting condition*, as a term of interest, was directly and most strongly linked to *Obamacare* and *ACA*, which were mentioned with *preexisting condition* in multiple comments. This finding was consistent with a key ACA provision: insurance companies cannot use applicants' medical history to deny coverage or charge higher

XSL•FO
RenderX

premiums based on their preexisting conditions [43]. Network structure's alignment with existing knowledge speaks to its structural relevance. *Preexisting condition* is located close to *premium*,*deductible*, *pricing*, market-related terms, and *government regulation* from cluster 4 about politics, as well as to *private health insurance* and *copay* on the far right of cluster 2, which is mostly dedicated to health care services. Therefore, when YouTubers discussed the US health care system, they used a noun phrase *preexisting condition* at the semantic intersection of health care politics and legislation, insurance pricing, and health services access.

In summary, the 323 networked terms, identified as most relevant by VOSviewer, unveiled discussions about illness and wellness; health services; ideology and society; the politics of health care agendas and reforms, market regulation, and health insurance; health care workforce; dental care; and concerns such as long wait times.

Before we removed 5575 duplicate comments, our original cluster map (Figure S1 in Multimedia Appendix 1) was quite similar to the cluster map in Figure 1. Our inquiry into the medical debt cluster comments uncovered repeated comments by a single YouTube user. After deletion, this cluster disappeared, but the network's overall structure largely remained intact, demonstrating its robustness.

Next, we examined clusters and nodes using overlays that reflected 2 aspects of the YouTube platform: the videos that elicited comments and the commentary itself. We assessed the usefulness of custom overlays as contextualization tools: Do they improve our understanding of nodes, node groups, and clusters? While we presented data on both video attributes and comment attributes, our analysis prioritized overlays depicting comment characteristics because they are more valuable for understanding digital publics' discussion of the US health care system.

Distribution of Video Groups Across Network Clusters

Thematic alignment between the video content that elicited the commentary and the commentary itself speaks to the content representativeness of the VOSviewer term co-occurrence network. The distribution of comments from 10 thematically diverse YouTube video groups across our term network is shown in overlays in Figure S2 in Multimedia Appendix 1. Our main findings are summarized in Table 1.

We observed substantial thematic congruence between video content and cluster terms. Nodes with above-average concentrations of comments related to the health care workforce were closely grouped in cluster 5, encompassing terms about nurses, staffing shortages, and management. Unlike most nodes in cluster 5, which were associated with health care workforce videos, the term *respect* had an above-average share of comments related to ACA and Obamacare reform videos. Our analysis of comments indicated that commenters mentioned respect for nurses, which explained the placement of *respect* in cluster 5. In addition, many comments on ACA and Obamacare reform videos expressed respect for Senator John McCain, which explained the connection between the term *respect* and *McCain*. *Respect*'s placement within cluster 5 but at its outer boundary, in the direction of node McCain, coupled with video overlay evidence, suggested semantic accuracy and structural relevance of our network.

Videos from 2 groups (health care policies, politics, ACA, and Obamacare reform) generated comments in cluster 4, which consisted of numerous political and reform-related terms. In addition, videos about health costs, one of which was titled "Dollars and Dentists," elicited discussions of dental care (cluster 6). Comments on videos about health care systems in different countries produced terms that appeared in multiple clusters but mostly in cluster 2 about health services and cluster 7 about long wait time concerns. At the same time, a Home Box Office video "Medicare for All" featuring John Oliver and a Netflix video featuring stand-up comedians making jokes about the US health care produced comments in nodes scattered across the map. The Netflix video showcased many comedians and topics, one of whom, Wanda Sykes, spoke about opioids from the perspective of racial and ethnic minority people. A commentary on this topic appeared in nodes *pain* and *prescription* (left side of the map) and *race/racism*, *Black person*, and *White person* (right side of the map), where commenters debated racial disparities in pain medicine access. For race-related nodes, the share of comments on the Netflix video (comedy on the US health care) varied between 1% and 8%, indicating that it was not the only video prompting the discussion. This finding is not unique; it was common for terms to represent commentaries to a wide variety of videos or video groups.

Across all video group overlay legends, the highest scale midpoint was 0.25 for videos about health care costs and financial issues. It means that, on average, 25% (SD 14%) of comments within a term come from that video group. Across 323 map terms and 10 video theme overlays, there were only 11 (0.34%) instances (out of 3230 possible instances) where terms represented >90% of comments from a single video group.

XSL•FO
RenderX

Table 1. Characteristics of videos that elicited comments related to cluster-specific terms.

Cluster number (color)	Topical areas	Cluster's 10 largest terms	Video groups that elicited comments related to most, some, or specific terms within a cluster
1 (red)	Illness and wellness, including mental health and end of life	*Cancer, death, pain, food, disease, diabetes, young generation/person, life expectancy, chemotherapy,* and *cure*	• Children's health care (some terms) • End-of-life health care (some terms) • Health care systems in different countries (*young generation/person* and *life expectancy*) • Comedy on the US health care (*pain*) • Medicare for All video by John Oliver (*pain*)
2 (green)	Health services	*Surgery, ambulance (ride), prescription, appointment, wait time, specialist, insulin, testing, copay,* and *emergency room*	• Health care systems in different countries (most terms) • Medicare for All video by John Oliver (most terms) • Comedy on the US health care (*prescription*)
3 (dark blue)	Ideology and society	*Socialism (socialist), capitalism (capitalist), economy, war, communism (communist), security, media, police, crime,* and *democracy*	• Single-payer health care (most terms) • Health care systems in different countries (some terms) • Medicare for All video by John Oliver (some terms) • Health care costs and financial issues (*capitalism*) • Comedy on the US health care (*race/racism, Black person,* and *White person*) • ACA[a]/Obamacare reform (*race/racism, Black person,* and *White person*)
4 (yellow)	Health care politics, reform, market regulation, and insurance	*Trump, Biden, Obamacare, Republican, Democrat, McCain, premium, voting, free market,* and *debate*	• Health care policies and politics (most terms) • ACA/Obamacare reform (most terms) • Medicare for All video by John Oliver (some terms) • Single-payer health care (some terms) • Health care costs and financial issues (market regulation terms)
5 (purple)	Health care workforce	*Nurse/nursing, staff, Covid-19, vaccine, pandemic, respect, shortage, management, CEO*[b], and *shift*	• Health care workforce (most terms) • Health care systems in different countries (vaccine) • ACA/Obamacare reform (*respect*)
6 (light blue)	Dental care	*Dentist, teeth, dental care, dentistry, implant, dental insurance, cleaning, cavity, filling,* and *brace*	• Health care costs and financial issues (most terms)
7 (orange)	Concerns	*Long wait time, cancer patient, DMV*[c], *urgent treatment,* and *death panel*	• Health care systems in different countries (most terms) • Single-payer health care (*DMV*)

[a]ACA: Affordable Care Act.

[b]CEO: chief executive officer.

[c]DMV: Department of Motor Vehicles.

Comment Date and Ongoing Discussions

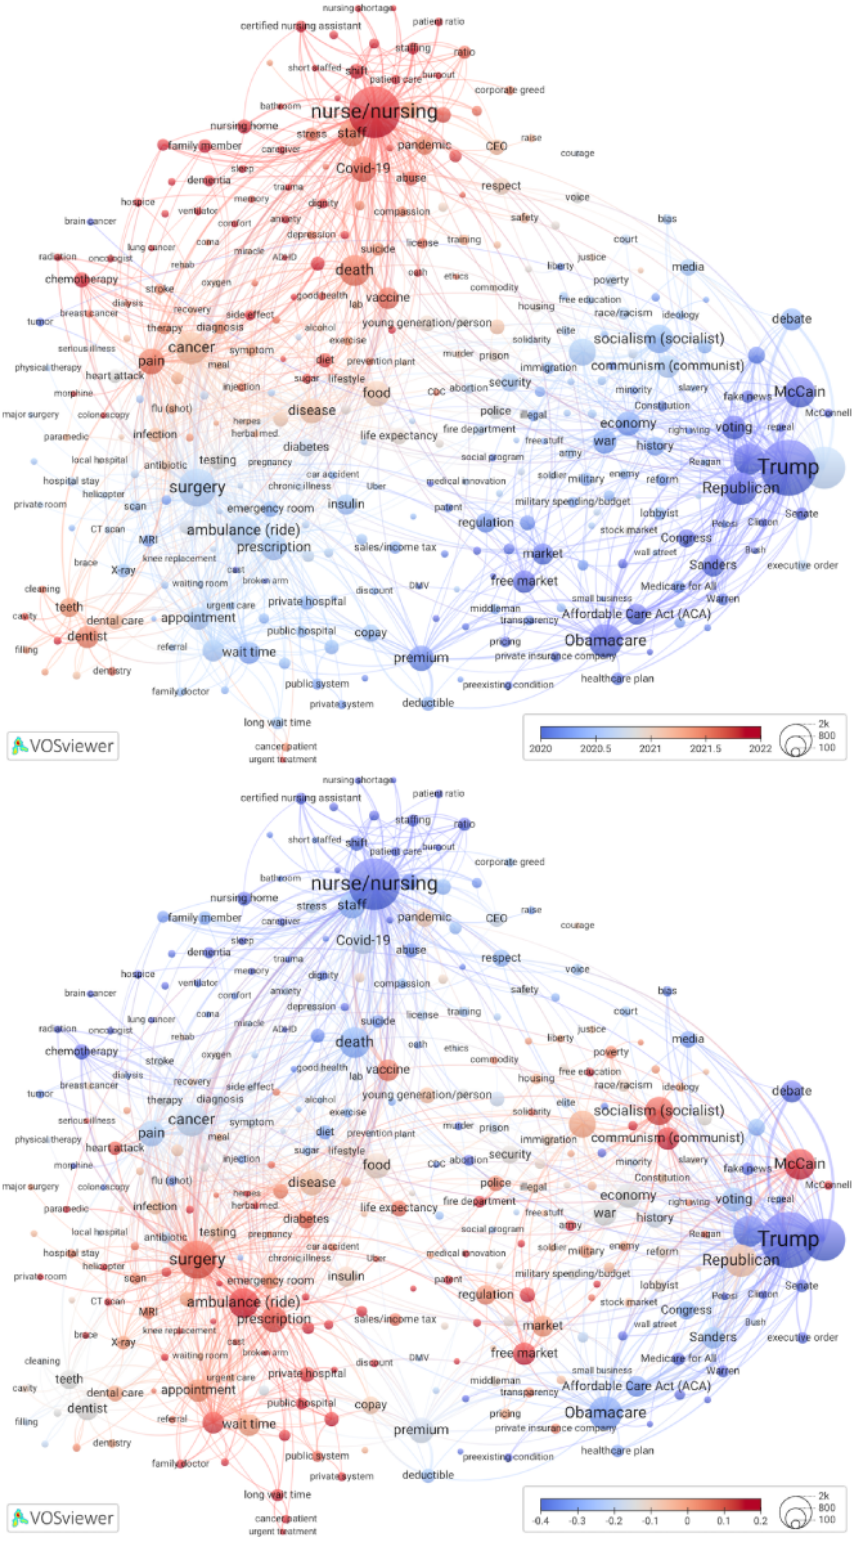
When considering the timing of comments, the overall mean for all nodes was December 2020 (mean 2020.99, SD 0.81; range: from early 2018 for *repeal*, referring to the Trump administration and Republican lawmakers' efforts to repeal the ACA, to early 2023 for *do-not-resuscitate*). Clusters 1, 5, and 6 have terms with more recent comments than other clusters (Figure 2, left [42]), which is likely a function of when a video was uploaded on YouTube.

Also shown in Figure 2 are ongoing discussions, conceptualized at the term level as mean posting time since the first comment in the respective video. We calculated time for each comment, based on the video it came from, then averaged across all comments behind each term. The terms that scored above the midpoint of 0.49 years (approximately 6 months) highlighted areas on the map where YouTube users continued to contribute comments long after the videos were posted, serving as a proxy for ongoing interest and engagement. Comment scores were calculated in 2 ways: without standardization, expressed as a fraction of a year (Figure S3 in Multimedia Appendix 1), and with standardization, using the base-10 logarithm to adjust for skewed data. The standardized scores were then normalized so

XSL•FO
RenderX

that the mean is 0 and the scale points represent SDs (Figure 2, right).

Ongoing discussions in cluster 1, "illness and wellness," were about cure (*herbal medicine* and *herpes*), *diabetes*, and life expectancy, and young people persisted, on average, for 11 months. In cluster 2, "health services," ongoing discussions revolved around ambulances, specialist care, prescriptions, appointment wait times, copays, and private (vs public) health insurance or services, roughly covering the same area as high-scoring nodes in an overlay for videos about health care systems in different countries. YouTube commenters demonstrated continued interest in these topics. On average, cluster 2 terms that scored above the mean came from comments posted approximately 9 months after the first comment on a given video.



In cluster 3, "ideology and society," YouTube users' comments on political ideologies, police, and military were typically added around the 8-month mark, on average. To better understand an unexpectedly salient group of ideological terms in our map, we analyzed hundreds of comments about communism, socialism, and capitalism. Our analysis confirmed node size and interconnectedness. The discussion of the US health care system was highly politicized, with ideological battles that revolved around dichotomies, such as socialism versus capitalism. Individuals who self-identified as capitalist, conservative, libertarian, or Republican outright rejected any government involvement in health care, calling it socialism, which was often equated with communism (thus confirming node proximity), social democracy, inefficiency, economic decline, and excessive control. Commenters who self-identified as progressive, liberal, social democrat, or left leaning pointed out that health care in the United States was already a mix of capitalism and socialism: publicly funded US police and army were essentially socialized law enforcement, similar to socialized medicine in other countries. They saw no logical reason to reject socialized medicine.

Moreover, several non-US commenters and US residents living abroad shared their positive experiences with health systems in Europe and elsewhere, pointing out that they were affordable to residents with low-income status. Commenters questioned the following: Why do Americans accept *GoFundMe* fundraising to cover medical expenses but not universal health care? Those who defended capitalism praised it for *medical innovation* and high quality of health care but often added that it must be properly regulated. Application of capitalist principles to the US health care system was also discussed in connection to greed, lack of access to health care services, inequities, and poor outcomes. Multiple comments suggested that every economy needed a mix of socialism (relating it to public good or public welfare) and regulated capitalism to counterbalance corporate interests.

Finally, in cluster 4, "health care politics, reform, market regulation, and insurance," we observed ongoing discussions about market-related topics (*monopoly*, *regulation*, and *market*) and especially the role of John McCain during Obamacare repeal.

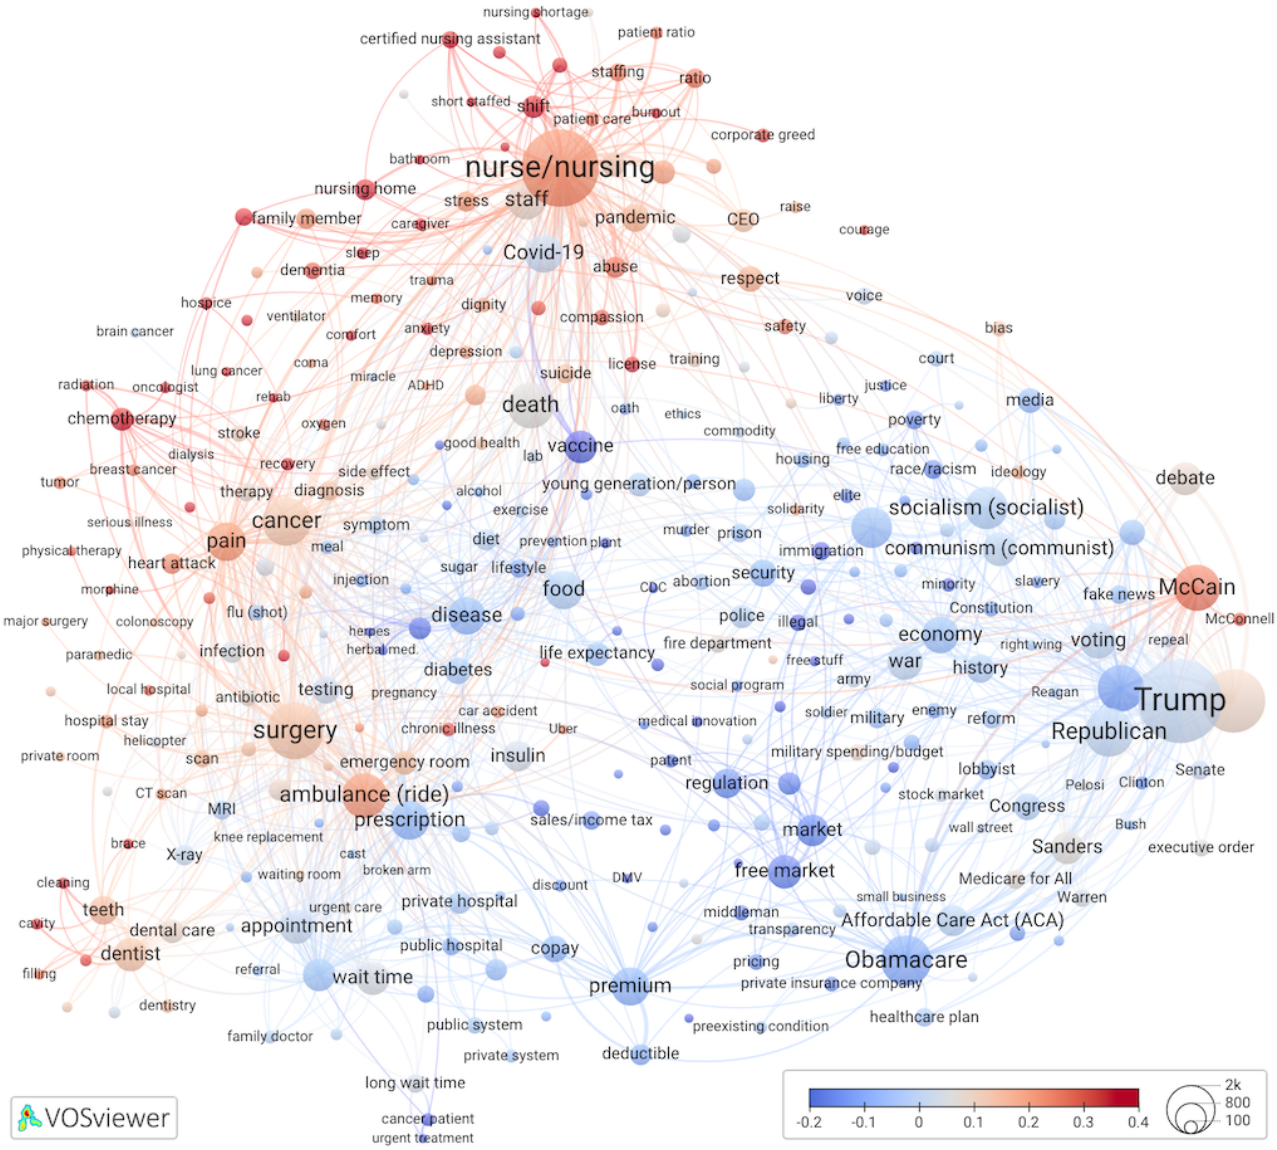
XSL•FO
RenderX

Figure 2. Overlays to Figure 1 for mean comment date (top) and ongoing discussions (standardized scores, bottom). High-resolution versions are available in Multimedia Appendix 1 (Figures S4 and S5).

Comment Likes

Comment likes were standardized using the same method as for ongoing discussions. We examined overlays for cluster-specific concentrations of terms that scored above the mean, identified dyads of linked terms that scored high, and summarized the most-liked comments from a specific cluster or term.

In Figure 3 [42], the largest concentrations of above-average liked comments were mostly cluster specific (clusters 1, 2, 5, and 6). Most-liked cluster 5 terms came from comments about shortage of nurses and nurse burnout as well as factors contributing to it (*shift*, *short staffed*, *corporate greed*, *patient ratios*, *abuse*, and *management*). We checked an unexpected connection between *shift* (0.58 SD above the mean for all terms) and *bathroom* (0.48 SD above the mean), which represented



XSL•FO
RenderX

highly liked comments. A total of 20 unique commenters shared stories of extreme job demands, describing how nurses worked long shifts, endured heavy workloads, faced high patient-to-nurse ratios, and had to wait for breaks to address their physiological needs. All but 3 commenters self-revealed their profession. They were experienced nurses, practicing or retired, or nursing students on clinical rotations. Their detail-rich comments described burnout antecedents, such as profits over staffing, mistreatment of nurses, and mandatory overtime, and outcomes, for example, reduced patient care quality and medication errors.

In cluster 1, cancer-related terms, the term *sleep*, and end-of-life terms such as *do-not-resuscitate* were extracted from comments with many likes. Individuals who mentioned "do not resuscitate" (DNR; 0.42) expressed deeply personal desires for autonomy and the avoidance of prolonged distress at the end of life. The commenters identified themselves as older adults, patient advocates, veterans, or health care workers. They discussed the implications of DNR orders, sometimes expressing doubts that an overburdened health care system could handle their implementation in a patient-centered way. Nevertheless, some nurses who witnessed slow deaths of patients without DNR orders chose to create their own advance directives.

Comments about *sleep* were also well liked (0.43) but, unlike the DNR discussion, referred to many different contexts: caregivers, including nurses, experiencing stressors and sleeplessness; sleep as a precondition to wellness; and in the context of passing away peacefully in one's sleep. The placement of *sleep* within our network, on the boundary of cluster 1 terms (*dementia, family member, nursing home*, and *caregiver*) and cluster 5 terms (*stress, trauma*, and a direct link to *nurse/nursing*), matched these observations and provided evidence of semantic accuracy and structural relevance.

Figure 3. A mean comment likes (standardized) overlay to Figure 1.

Among dental treatment nodes in cluster 6, *cavity* scored the highest (0.48) on comments with likes. Cavity-related comments came from individuals who revealed the following self-identifications: residence (mostly the United States but also US residents living abroad and foreign nationals from multiple continents), low income (jobless or poor), and medical tourists

XSL•FO
RenderX

(eg, US residents receiving dental treatments in Mexico). Commenters particularly liked quotes of low dental costs in Australia, France, Mexico, and other countries; stories of cost savings after buying airfare and paying for dental treatments abroad; personal accounts of dentists recommending unnecessary procedures; and oral health tips, such as reducing sugar intake. Comments specified systemic problems with US dental care: financial strains, even with dental insurance; potentially superfluous, according to second opinions, or unnecessarily extensive procedures (eg, on baby teeth); worsened conditions due to cost-related treatment delays; and processed sugar industry's influence on consumption of foods, leading to dental decay.

Other clusters also had node groups that were well liked. We explored 2 dyads of linked nodes that scored high on likes: *McCain–McConnell* (0.31-0.34, cluster 4) and *ambulance (ride)–Uber* (0.26 for both, cluster 2), with above-average likes. In first dyad comments, most commenters applauded McCain's vote that helped prevent the repeal of ACA and criticized McConnell and other Republicans. Comments from the second dyad, *ambulance* and *Uber,* were by YouTuber users who expressed concerns about the cost of US ambulances and Americans' reluctance to use specialized emergency transportation. To avoid unpredictable costs, some US commenters planned to use nonmedical transport, such as ride-sharing services like Uber, during health emergencies.

Comments With Select British Spellings

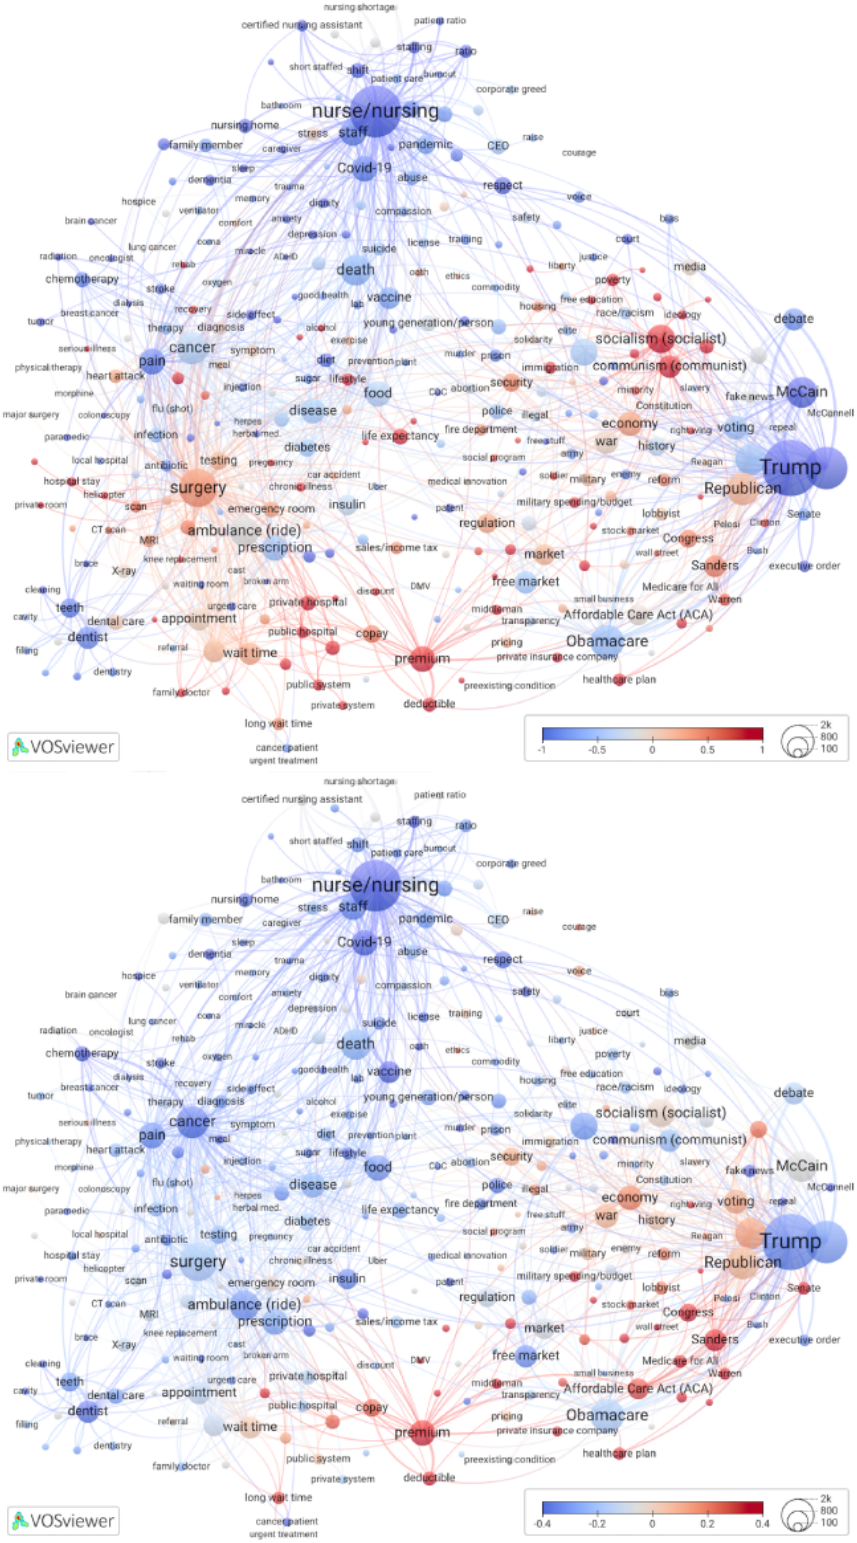
Figure S6 in Multimedia Appendix 1 displays an overlay that approximates contributions from commenters whose backgrounds are associated with regions where British spelling conventions are more common than in the United States. Such spelling was detected in multiple clusters, but the highest-scoring terms were in cluster 2 (*national insurance*, *government hospital*, and *private system*) and cluster 3 (*free education*, *unemployment*, and *justice*).

Commonly Mentioned Health Care Concepts: System Design Ideas

Our last set of overlays demonstrates the distribution of comments that mention policy-relevant ideas on health care system design: universal health care, Medicare for All, a single-payer system, and socialized medicine (Table 2). VOSviewer Online offers a modifiable legend with an option to normalize term scores by subtracting mean and dividing by SD. When term scores are normalized, we can directly compare multiple overlays (Figures 4 and 5 [42]) to identify map areas with terms that are extracted from a high (vs low) share of comments mentioning specific system design ideas. Unlike the standardization of comment scores, normalization is performed at the term level.

Table 2. Mentions of health care system design ideas.

Attributes	Design idea overlay[a]			
	Universal health care	Medicare for All	Single payer	Socialized medicine
Definition[b]	A system where all citizens have access to health care services without financial hardship	A proposed system to expand the US Medicare program to cover all individuals, eliminating private insurance	A system where a single entity (usually the government) pays for all health care costs	A system where the government not only funds but also provides the health care services
Comments, N	3638; "universal health" or "universal healthcare"	2909; M4A or "medicare for all"	1474; "single payer" or "single-payer"	716; "socialized medicine" or "socialised medicine"
Prevalence of comments that mention each design idea within a term-specific comment collection				
Highest-scoring term on a corresponding overlay	*Private room* (12/95, 12.6% of comments also mention universal health care)	*Warren* (116/276, 42% of comments also mention Medicare for All)	*Administrative cost* (16/108, 14.8% of comments also mention single payer)	*Medical innovation* (5/108, 4.6% of comments also mention socialized medicine)
Share of comments within ideological terms[c]				
Socialism/socialist	+1.44 SD	+0.04 SD	−0.16 SD	+0.64 SD
Communism/communist	+3.06 SD	−0.18 SD	−0.65 SD	+0.45 SD
Capitalism/capitalist	−0.33 SD	−0.28 SD	−0.49 SD	−0.53 SD



[a]Interactive overlays are available from the left panel (view>items>color >) [42].

[b]Commenters defined health system design ideas in different ways and sometimes used them interchangeably. For example, some commenters talked generally about a state-managed health care system in reference to both single payer and socialized medicine.

[c]Normalized health system design idea overlay scores for 3 ideology nodes are shown relative to all nodes' mean share of comments mentioning that specific health system design idea. Plus or minus signs refer to above or below all terms' mean share, expressed in SD units, within each health system design idea overlay.

RenderX

Figure 4. Overlays to Figure 1 depicting the distributions of comments that mention “universal health” (top) and “Medicare for All” (bottom). High-resolution versions are available in Multimedia Appendix 1 (Figures S7 and S8).

XSL•FO
RenderX

Figure 5. Overlays to Figure 1 depicting the distributions of comments that mention "single-payer" (top) and "socialized medicine" (bottom). High-resolution versions are available in Multimedia Appendix 1 (Figures S9 and S10).

As shown in Table 2, the most frequently mentioned health system design idea in our comments—universal health care—was discussed in connection to *private room*, the highest-scoring term on the universal health overlay. The term *private room* also had above-average share (3/95, 3%) of comments, with at least 1 (6%) of 18 British-spelled words. US residents and foreign nationals discussed semiprivate and private hospital rooms as a desirable high standard for hospital stays. Commenters with experience in universal health systems explained that such systems serve everyone but may not provide extra luxuries unless a patient is also covered by private insurance or pays out of pocket. Several comments expressed preferences for universal health care systems with balanced public and private health care. Private rooms, marble floors, and hotel-like amenities in US hospitals were discussed as

XSL•FO
RenderX

luxuries available to the rich, while care was being denied to the poor.

At the bottom of Table 2, we show 3 ideological terms and compare the extent to which they are linked to each health system design idea. For universal health overlay, the data address the following question: In node *socialism/socialist*, what is the share of comments that mentioned universal health and how far is this share, in SD units, away from the universal health care overlay's mean for all nodes? Compared to 3 other concepts (Medicare for All, a single-payer system, and socialized medicine), universal health care was most strongly linked to discussions of communism and socialism. Specifically, the share of universal health care comments in the node *socialism/socialist* was much greater than that in most other nodes (1.44 SD above all terms' mean). It was even higher for the node *communism/communist* (3.06 SD above the mean).

While discussing Medicare for All in early 2020, YouTube commenters were concerned that it was insufficiently supported by Elizabeth Warren, as compared to Bernie Sanders, which explains why *Warren* was the highest-scoring term in the Medicare for All overlay. In addition to questioning the political viability of Medicare for All, commenters expressed concerns about its funding and tax increases, possible loss of preferred private insurance, unemployment among health insurance workers, increased wait times, diminished quality of care, and fluctuating government or political control over reproductive health.

The highest-scoring term on the single-payer overlay, *administrative cost*, was often mentioned with a term *middleman*, an unnecessary intermediary, for example, private insurance companies and for-profit corporate interests. Discussions of single payer, administrative costs, and middlemen turned into debates. Advocates cited the potential for significant savings and increased efficiency by eliminating the profit-driven insurance model. They pointed to Medicare's low overhead as evidence that a single-payer system could reduce administrative costs. By cutting out middlemen, single-payer systems bring down administrative costs and simultaneously simplify system navigation and transactions for patients, restrain profiteering, reduce health care fraud, and open health care systems to cost control. Critics, however, expressed skepticism about the efficiency of government-run systems, cautioning that replacing one bureaucratic structure with another may not achieve the expected reductions in administrative costs.

Finally, the term *medical innovation* had the highest share of comments that mentioned socialized medicine. The comments often referred to the United States's top position in producing medical innovations. Several US commenters suggested that countries with socialized medicine rely upon US innovations without contributing comparable advancements in new treatments or medical technologies. US medical innovations, according to their comments, come at high cost but also contribute to high quality of care. Others expressed disagreement, saying the United States ranked fourth on medical innovation, behind Switzerland, Germany, and the Netherlands. In addition, hopes were expressed that rising costs of US health care could be controlled through medical innovations, especially in older adult care.

Of the 4 health system design ideas we analyzed, the concept of single-payer health system had the lowest use of ideological terms. The distribution of scores across the single-payer overlay shows that single-payer discussions were less prevalent in ideological terms (*socialism/socialist*, *communism/communist*, and *capitalism/capitalist)* than in other terms we mapped. In the *socialism/socialist* node, an above mean share of comments about Medicare for All (+0.04 SD), socialized medicine (+0.64 SD), and especially universal health care (+1.44 SD) indicated greater use of ideological terms, as compared to single-payer discussions (–0.16 SD). In addition, the universal health care discussion was much more centered around communism or communist (+3.06 SD) compared to the single-payer discussion (–0.65 SD).

Discussion

Overview

We discuss 2 sets of findings. First, we summarize our evaluation of the semantic network. We elaborate on the implications of repurposing VOSviewer to subsequent social media studies and anticipate scientific advances that may result from its broad application. Second, we summarize our US health system insights and discuss their policy implications, pointing out limitations.

VOSviewer Term Co-Occurrence Network as a Social Media Analysis Method

VOSviewer is one of several programs available to researchers for conducting semantic network analysis. For example, previous studies have used the Fruchterman-Reingold algorithm [44], Gephi [45], and R [46] to build semantic networks. At the same time, VOSviewer's user-friendly interface is suitable for users without advanced technical skills. Regardless of the tools used in their construction, semantic networks promise to represent knowledge, while their interconnected nodes likely capture meaning [12], as demonstrated by this analysis.

We used VOSviewer as a data visualization tool to respond to the critical need to decrypt chaotic and extensive social media discussions on a socially important topic. Our analysis suggests that VOSviewer produces visualizations with high information density, interactivity, and interpretive richness. In addition, we obtained evidence regarding the following characteristics of the VOSviewer-generated network: (1) robustness or resilience to variations in data, (2) content representativeness of the diversity of issues related to the US health system, (3) structural relevance defined as meaningful network relationships, and (4) semantic accuracy defined as accurate representation of comment meaning. Our evaluation of the network's decision support usefulness is discussed in the US Health System Insights and Their Policy Implications section.

First, our limited test of robustness confirmed the network's resilience to the removal of approximately 3% of repeated comments from our corpus. If such comments were retained, identical comments by just 1 social media user would have

XSL•FO
RenderX

produced a user-specific map cluster about medical debt and bankruptcy. Striving to build a network reflective of broad conversations, we chose to remove it, but the comments we removed were relevant to the US health system. The person who posted them might have tried to express desperation or draw attention to the seriousness of medical debt.

Second, the network comprehensively covered 10 thematic video groups, representing the entire diversity of video content about the US health care system. In other words, comments from all video groups were represented within the network nodes. Third, we observed a meaningful cluster layout that, overall, could be intuitively interpreted. Structural relevance was confirmed by spatial arrangement of nodes in the network, where the proximity of nodes corresponded to the co-occurring nature of the semantic relationships observed in the text from which the nodes were derived. Moreover, the network's structure aligned with existing knowledge, for example, ACA provisions. Forth, multiple checks confirmed that the mapped terms, including unexpected or ambiguous ones, captured the meanings of posts as well as their context.

Anticipated Scientific Advances of the VOSviewer Application to Social Media Analyses

The VOSviewer's term co-occurrence mapping method and their custom overlays can advance computational social sciences through informative, contextualized semantic networks. Natural language processing enables unbiased extraction of relevant terms, with an option of manual term screening. Revealing large patterns in extensive source data, VOSviewer "visual narratives" [47] can guide researchers to efficiently allocate their analytical resources as they explore salient patterns of societal importance embedded in "context or domain-specific knowledge" [48]. As such patterns involve network terms—nouns and noun phrases that occur in comments—researchers can strategically focus on the most promising subsets of extant data. In addition, VOSviewer-enabled semantic networks bring to light the interdisciplinary nature of social media studies. According to our cluster map, an in-depth analysis of public perceptions of the US health system calls for input from scholars in fields such as communication, economics, health care management, medicine, political science, public health, and others.

Clusters model thematic structure at a macro scale; overlays provide interpretive richness. The method we demonstrated here offers a valuable way for researchers to experience relationships embedded in source data, some of which are hard to document using conventional analyses. Chronological overlays that show video dates, comment dates, and lags in time between the first and the nth comment offer clues on how the discussion progressed over time, enabling a study of unfolding discourses. This is particularly relevant for data from social media platforms, which are "inherently longitudinal" [48]. With additional automation, it would be possible to create dynamic network visualizations that are updated in near–real time as new comments are posted.

Another benefit of semantic map overlays is that they foster cluster exploration and hypothesis testing by combining different data sources. For the YouTube platform, overlays may reflect characteristics of comments, YouTube video channels, videos themselves, or social media users' channels. Therefore, visual overlays represent many opportunities for innovation and experimentation. For example, information excluded during term selection can be brought back in overlays. In this study, we removed geographical references from the cluster model's nodes but created an overlay to highlight discussions with British spelling.

The method we demonstrated in this study can also enhance the value of qualitative research. Resource-intensive qualitative methods can be deployed strategically, guided by the grasp of larger patterns evident in semantic networks. Semantic networks can be contextualized and nuanced through qualitative coding. The qualitative codes can then be incorporated into custom-designed overlays, leading to new hypotheses and qualitative analyses. This iterative approach enables visualization-assisted qualitative inquiry.

Given these methodological strengths, we believe that VOSviewer-enabled semantic network analyses of social media data can advance social science research in the digital era. Thinking even broader, the proposed method can be applied across a variety of contexts and data sources, not limited to social media, and across different disciplines, such as computational humanities.

US Health System Insights and Their Policy Implications

Overview

Health care debates unfold in both in real life and online spheres. We examined digital publics' discourse about the US health care system in response to YouTube videos from right, center, and left media outlets. The YouTube platform allows purposeful selection of videos by varied media outlets on different aspects of an issue. We provided evidence that thematic diversity of videos was passed on to the commentary, opening a door to the policy-relevant analysis of diverse viewpoints. The YouTube platform has emerged as a space for heated debates, thoughtful ideas, misconceptions, and personal narratives in response to the US health care system.

Understanding the viewpoints by social media users provides valuable input for policy makers, health care professionals, and advocates aiming to shape effective reforms. The insights gleaned from the VOSviewer semantic network carry significant implications, which we grouped into 3 categories (concerns about the health care system, domestic and global interconnections in health care discussions, and informing change through key health care discourse insights).

Concerns About the Health Care System

The clusters shed light on a wide range of areas of concern within the US health care system, including those that are likely to be voiced by the public when politicians mention universal health care, Medicare for All, a single-payer system, and socialized medicine. The network analysis was helpful in estimating the use of ideological terms in discussions of various health system design ideas and identifying related concerns, for instance, about continued medical innovation or patients' access to private hospital rooms. The ideology and society cluster

XSL•FO
RenderX

terms, derived from politicized comments, reflect the entrenched ideological conflicts and capitalism-socialism dichotomies within the YouTube discourse about the US health care system.

We observed that comments in the health care workforce cluster, particularly those about staff shortages and burnout, received many likes. This pattern points to a widely shared perception of the urgent need to address challenges faced by nurses and other health professionals. If corroborated across time and other data sources, this sentiment may translate into public support for health care reforms that enhance workforce well-being, improve nurse-to-patient ratios, and support the essential role of health care workers in the system.

Online discussions also highlight ongoing debates about the balance between public and private health care services. Policy makers can use these insights to formulate strategies that optimize the strengths of both sectors, ensuring accessibility, affordability, and quality of care. In sum, a VOSviewer-generated semantic network with overlays shows promise as a decision support tool for policy makers.

Domestic and Global Interconnections in Health Care Discussions

Health care reforms should consider the broader societal and political context of the country to build sustainable and politically viable solutions. The health care discourse we described incorporated widespread debates about political ideologies, societal issues such as racism, and economic considerations. While many of these issues were domestic, there was also a significant international component. Terms such as *national insurance, government hospital, private system, free education, unemployment,* and *justice* represented 6% to 8% of comments with at least 1 British-spelled word from our list. In much smaller concentrations (2.5%-4%), British-spelled comments appeared in the wellness discussion (*nutrition, vegetable,* and *memory*) and conversations about tax break (or cut), social health care, and private insurance companies. Adding evidence in support of semantic accuracy, several terms extracted from a nonzero share of British-spelled comments (*national insurance* and *social health care*) described societies outside of the United States.

The presence of British-spelled words in our data indicated the global nature of US health care discussions, which is evident in international comparisons of prices and patient experiences. YouTube discussions offered opportunities for US social media users to learn about foreign health systems and explore their benefits, trade-offs, and foundational values. The information was conveyed not by experts or politicians but by laypeople who had encountered foreign systems as taxpayers and patients. Some informants lived in several countries and could compare multiple systems. Informed by global perspectives, the US public may shift its expectations, prompting politicians to incorporate best practices, for example, affordable drugs and predictable costs of emergency patient transportation, into reform initiatives. At the same time, both the public and policy makers stand to benefit from reexamining their own misconceptions and rigid ideological beliefs in light of successful health care models and practices in other countries.

Informing Change Through Key Health Care Discourse Insights

Our semantic network analysis provides insights into the topics that garner the most attention and engagement in ongoing discussions. Health care reforms can be supported by targeted public education and awareness campaigns addressing these key themes, fostering informed public discourse and encouraging active participation in the reform process. Accordingly, policy makers should continuously monitor public sentiments on platforms such as YouTube to inform dynamic, responsive health care policies that adapt to changing societal needs and concerns. Finally, leveraging user engagement patterns, particularly standardized likes and ongoing discussions, can establish effective feedback loops between policy makers and the public. Understanding which aspects of the discourse resonate most strongly with the public allows for the refinement of reform strategies. We provided empirical evidence of links between specific public opinions on health system designs and ideological discourse; comments about universal health care had a much higher use of ideological terms than discussions of single-payer health systems. Overall, the key takeaways drawn from the VOSviewer-generated semantic network analysis provide actionable insights for shaping reforms in health care, which are responsive, inclusive, and aligned with the diverse perspectives expressed by the public on digital platforms.

Finally, we share 2 observations on how VOSviewer maps may support evidence-based policy making and communicating with stakeholders. One consideration is the empirical rootedness of the information we mapped. Decision makers are more likely to accept and act upon information perceived as “evidence based” [48], for example, maps that display intuitively interpretable terms grounded in actual text. In the study by van der Voort et al [47] on big data, decision makers “wanted ‘stories to tell’ to feed public debate and highlight problems and opportunities,” favoring reports at higher resolutions. In our study, clusters communicated broad narratives about the public discourse of the US health system, while overlays enriched and contextualized interpretation of narratives, adding complexity and specificity.

How well decision makers with different levels of education can decode VOSviewer data visualizations remains to be tested. We anticipate that for most decision makers, the learning curve of interpreting maps will be less steep than that for statistical outputs with comparable informational value. While overlays provide a multidimensional understanding of the discourse, they may be harder to decode than clusters. At the same time, the interactive nature of VOSviewer Online is likely to add interest and user engagement, helping to translate research findings into informed decision-making and actionable policy measures.

Limitations

While VOSviewer offers a powerful tool for visualizing and analyzing co-occurrence networks, the algorithm’s effectiveness is contingent on the initial selection of terms. The manual screening of a list of terms introduces a potential bias. In addition, the study is limited to English language YouTube comments, which may not fully capture the broader public discourse on health care.

XSL•FO
RenderX

Further research is warranted to validate and expand upon our results. Future studies could use other advanced natural language processing techniques to enhance the accuracy of term selection and clustering. Moreover, a multiplatform analysis that includes other social media platforms and online forums would provide a more comprehensive understanding of public sentiment and discourse surrounding health care.

Acknowledgments

The authors sincerely thank Dr Rodina Bizri-Baryak for her valuable contributions to data collection, which greatly enhanced the depth and breadth of this study.

Data Availability

All data are available in the main text or Multimedia Appendix 1. Map files can be downloaded from map URLs provided in Multimedia Appendix 1. Original YouTube comments (initial comments and first-level replies) can be accessed through YouTube using the video descriptions provided in Multimedia Appendix 1.

Authors' Contributions

LVI conceptualized the study, curated the data, conducted the formal analysis, created the visualizations, provided supervision, and managed the project administration. LVI and EE collaborated on writing the original draft, methodology, investigation, validation of the findings, and contributed to the writing, review, and editing of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: *Hikikomori* syndrome is a form of severe social withdrawal prevalent in Japan but is also a worldwide psychiatric issue. Twitter (subsequently rebranded X) offers valuable insights into personal experiences with mental health conditions, particularly among isolated individuals or hard-to-reach populations.

Objective: This study aimed to examine trends in firsthand and secondhand experiences reported on Twitter between 2021 and 2023 in the Japanese language.

Methods: Tweets were collected using the Twitter academic research application programming interface filtered for the following keywords: “#引きこもり,” “#ひきこもり,” “#hikikomori,” “#ニート,” “#脱ひきこもり,” “#不登校,” and “#自宅警備員.” The Bidirectional Encoder Representations From Transformers language model was used to analyze all Japanese-language posts collected. Themes and subthemes were then inductively coded for in-depth exploration of topic clusters relevant to first- and secondhand experiences with *hikikomori* syndrome.

Results: We collected 2,018,822 tweets, which were narrowed down to 379,265 (18.79%) tweets in Japanese from January 2021 to January 2023. After examining the topic clusters output by the Bidirectional Encoder Representations From Transformers model, 4 topics were determined to be relevant to the study aims. A total of 400 of the most highly interacted with tweets from these topic clusters were manually annotated for inclusion and exclusion, of which 148 (37%) tweets from 89 unique users were identified as relevant to *hikikomori* experiences. Of these 148 relevant tweets, 71 (48%) were identified as firsthand accounts, and 77 (52%) were identified as secondhand accounts. Within firsthand reports, the themes identified included seeking social support, personal anecdotes, debunking misconceptions, and emotional ranting. Within secondhand reports, themes included seeking social support, personal anecdotes, seeking and giving advice, and advocacy against the negative stigma of *hikikomori*.

Conclusions: This study provides new insights into experiences reported by web-based users regarding *hikikomori* syndrome specific to Japanese-speaking populations. Although not yet found in diagnostic manuals classifying mental disorders, the rise of web-based lifestyles as a consequence of the COVID-19 pandemic has increased the importance of discussions regarding *hikikomori* syndrome in web-based spaces. The results indicate that social media platforms may represent a web-based space for those experiencing *hikikomori* syndrome to engage in social interaction, advocacy against stigmatization, and participation in a community that can be maintained through a web-based barrier and minimized sense of social anxiety.

KEYWORDS

hikikomori; social withdrawal; hikikomori syndrome; mental health; social isolation

Introduction

Background

Hikikomori syndrome, a form of severe social withdrawal largely characterized as experienced among adolescents and young adults in Japan, has recently gained increased attention as a global mental health concern [1]. Importantly, variability in reported *hikikomori* prevalence in countries and regions such as China, Hong Kong, South Korea, Singapore, Nigeria, the United States, and Taiwan may reflect different cultural distinctions of *hikikomori* inclusion criteria, study-specific assessments, and study-specific enrollment methods [2,3]. Nevertheless, increasing prevalence continues to challenge the notion that *hikikomori* is specific to the Japanese context and provides emerging evidence that this phenomenon is widespread cross-nationally [2,4]. Importantly, this form of extreme and persistent social isolation and withdrawal can be viewed as a complex sociocultural mental health phenomenon influenced by a variety of factors, such as economic and employment conditions, social norms and expectations, technology access and use, and changing attitudes toward acceptable social interaction (such as changes in interpersonal dynamics caused by the social isolation experienced during the COVID-19 pandemic) [5,6].

Hikikomori (derived from the verb *hik* [引き], which means to withdraw, and *komori* [籠り], which means to be inside) was originally coined by Japanese psychologist Tamaki Saito in 1998. The term was originally operationalized to refer to an individual who has stopped going to school (*futoukou* [不登校]) or work (*neeto* [ニート]) and has remained at home for a duration of >6 months [7]. A consensus on a standardized definition of *hikikomori* has not been reached, contributing to challenges in measuring the phenomenon, but a commonly used set of criteria was created in 2003 by the Japanese Ministry of Health, Labor, and Welfare (JMHLW) [1,4]. The JMHLW criteria have since been updated with the most recent 2010 definition, which describes *hikikomori* as a result of various factors, such as avoiding social participation (such as schooling, including compulsory education; employment, including part-time jobs; and other interactions outside the home), which in principle has continued under the condition of being housebound for a period of >6 months (this may include leaving the home while still avoiding interactions with others [8]). A later definition in 2020 by Kato et al [9] proposed updated diagnostic criteria for *hikikomori* as a pathological social withdrawal or social isolation in which the essential feature is physical isolation in one's home and for which the person needs to meet the criteria of (1) marked social isolation in one's home, (2) duration of continuous social isolation of at least 6 months, and (3) significant functional impairment or distress associated with the social isolation. Furthermore, many studies have found that patients with *hikikomori* syndrome often had experiences with bullying, peer rejection, or dysfunctional family life and were prone to internet addiction [10,11].

However, until recently, *hikikomori* was understood as a culture-bound phenomenon unique to Japan, reported to affect an estimated 1.2% of the population and over a quarter of students based on household survey data [2,12,13]. Although the causes and risk factors for *hikikomori* are not completely known, many studies have highlighted aspects of Japanese society and culture that enable *hikikomori* features and may account for the especially high number of *hikikomori* cases reported in Japan. Sociocultural factors such as *amae* (甘え), the Japanese term for codependency in parent-child relationships; the tendency of overprotection and indulgence of children by parents; the high-pressure environment created by the Japanese educational system; the need to conform to others and norms; and the challenging job search process for young adults often leading to identity distress have all been hypothesized to be causes of or risk factors for *hikikomori* [14-16]. Furthermore, the idea of isolation has been prominent in Japanese society for centuries. It has been seen as a way of life commonly represented in history with tales of mysterious mountain recluses and hermits [17]. However, numerous *hikikomori*-like situations and the lack of standardized diagnostic methods have made identifying *hikikomori* challenging in Japan [1].

Previous studies have attempted to carry out clinical interviews with families or study individuals who have sought help from public health centers for *hikikomori* syndrome, but the underlining challenges of social reclusion have also made *hikikomori* research and recruitment difficult [12]. Those who experience social and geographic isolation often feel unable to discuss mental illness openly due to the fears of stigma and may feel more comfortable sharing their experiences on the web [18,19]. In response, researchers have leveraged social media platforms as a source of self-reported health information that can be analyzed for stigmatizing issues and topics discussed among hard-to-reach populations, including generating insights specific to certain demographics and geographies [20,21]. Despite this possible application to *hikikomori* research, existing studies using web-based sources of data are limited and have primarily focused on exploring *hikikomori* through Western tweets outside of Japan and tweets in Japanese with limited keywords or have studied *hikikomori* alongside other mental health phenomena [22-24].

Objectives

Importantly, *hikikomori* has evolved since its introduction and original classification in 2003. While initially classified as a cultural syndrome in the 2019 version of the *Diagnostic and Statistical Manual of Mental Disorders*, it has since been included in the appendix of the 2022 *Diagnostic and Statistical Manual of Mental Disorders*, indicating that it will become a formal addition to the volume [25]. These changes may be a result of increasing public awareness, increased willingness to discuss mental health topics, and destigmatization yet can cause an expansion or inflation of the clinical meaning of *hikikomori* [26]. In response, this exploratory study sought to expand knowledge on *hikikomori* syndrome with a focus on

XSL•FO
RenderX

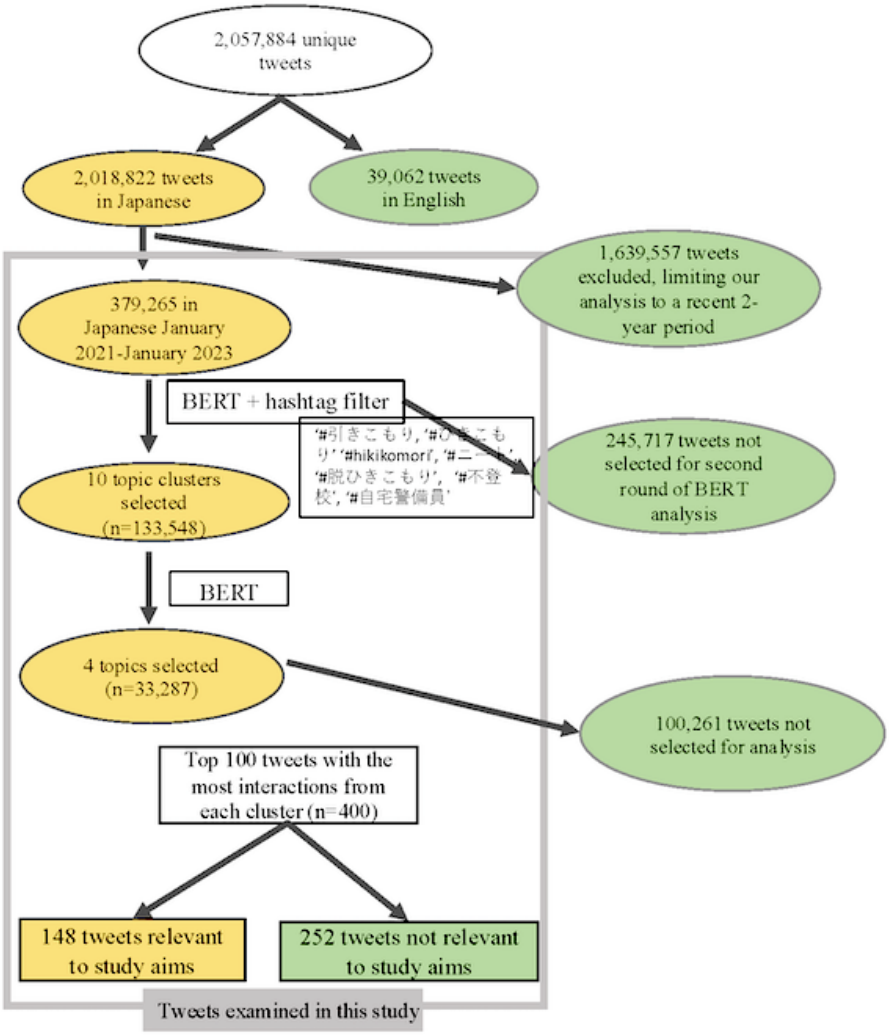
Japanese-language social media posts from Twitter (now known as X), a platform that is popular among Japanese web-based users. Furthermore, no study, to the best of our knowledge, has examined *hikikomori*-related data after 2020 (the start of the COVID-19 pandemic) despite the pandemic contributing to a rise in social isolation due to public health measures mediated by increased use of social media for social interactions [27,28]. We also sought to source more diverse data and web-based discussions by including additional keywords in Japanese, such as more casual terms, closely related words, and synonyms related to *hikikomori*. Finally, this study focused on firsthand and secondhand experiences self-reported by Twitter users and how those experiencing or who have had experience with *hikikomori* interact on the platform. The results of this study can provide insights into how the Japanese *hikikomori* population and their caregivers use social media to discuss this condition and promote a better understanding of primary concerns and behaviors that can help destigmatize this growing condition.

Methods

Data Collection

We first conducted manual searches of *hikikomori* posts on Twitter to identify keywords and hashtags associated with *hikikomori* conversations and mentions in the Japanese language. From this initial search, we identified a set of *hikikomori* keywords that Japanese-language Twitter users commonly used in web-based discussions regarding *hikikomori* syndrome (Multimedia Appendix 1). This initial set of keywords included nonspecific *hikikomori* keywords such as stopping going to school (*futoukou* [“不登校”]) or work (*neeto* [“ニート”]) and staying at home (“自宅警備員”), all terms that are considered a similar social phenomenon to *hikikomori* and often exhibit similar characteristics of social isolation as those included in the definition of *hikikomori* by the JMHLW. This approach was also supplemented by conducting an analysis of Google Trends data for related topics and queries associated with the Japanese-language spelling of *hikikomori* (“引きこもり”) from 2004 to the present, which identified additional related topic keywords used in this study.

After the study keywords were finalized, the Twitter application programming interface (API) was used to collect all Twitter posts (ie, tweets) in 50 languages, including Japanese and English. We then limited the data to the Japanese language only (ie, filtered data in the JSON language field *LANG* for the *JA* [Japanese] attribute); removed all retweets; and only included data over a 2-year time frame from January 1, 2021, to January 1, 2023. For the academic API data collection, the API had a limit of 300 queries per a 15-minute window, so the *next_token* feature was used to collect data continually between all queries to ensure that all available data in the given period were collected based on the API settings. The Twitter data field categories analyzed for this study primarily consisted of text, including the following fields: text, link, ID associated with the tweet, username (deidentified and not disclosed in this study), user link, author ID, API type, geolocation (latitude and longitude, if available), and tweet creation time and date. Data collection took place in June 2023.



Topic Modeling

Before topic modeling, any retweeted tweets were removed, and only unique tweets with a unique Twitter ID were analyzed. Due to the relatively large volume of data collected, we applied a natural language processing approach to group tweets into relevant thematic clusters. For this corpus of tweets, we used BERTopic, which is a topic modeling technique that leverages Bidirectional Encoder Representations From Transformers (BERT), and class-based term frequency–inverse document frequency, a statistical measure of the importance of words to a particular group of text, to create dense clusters allowing for easily interpretable topics while keeping important words in the topic descriptions. BERTopic then produced an output of data using the k-means algorithm, which includes the sum of the posts into a predetermined number of *k* clusters (*k*=10) based on the posts’ semantic similarities and groups text containing the same word-related themes into the same clusters. BERTopic was selected due to its use in previous work that has analyzed large-scale Twitter data, its general utility in analyzing unexplored themes that lack existing training data, and utility for the overall exploratory nature of this study’s aims [29,30]. Importantly, when compared against other traditional topic models, BERTopic has resulted in a better performance on both topic coherence and topic diversity on Twitter data [31]. Hence, BERTopic methodically has better utility to group tweets that are specifically relevant to *hikikomori* while reducing the potential for noise in selected clusters by providing more accurate and contextually relevant tweet conversational groupings. This study used BERTopic version 0.6.0 with Python version 3.7 (Python Software Foundation).

For the purposes of analyzing tweets specific to the aims of this study, BERTopic was executed in 2 phases: an initial round on the full dataset after data cleaning followed by a second round of focused analysis on relevant, selected topics. Data cleaning performed before the BERTopic analysis included removing punctuation and stop words in posts for optimized BERTopic grouping output. For the initial BERTopic analysis, we ran both 1- and 2-gram analyses on the same dataset to obtain the most visibility of content in our dataset. From both results, we selected 10 clusters in total for review. From those 10 clusters, we limited the data to the following hashtags—“#引きこもり” (“*hikikomori*”), “#hikikomori,” “#ニート” (“*neeto*”), “#脱ひきこもり” (“stopping *hikikomori* lifestyle”), “#不登校” (“prolonged absence from school”), and “#自宅警備員” (“home security guard”)—to further reduce the data size (see Figure 1 for a summary of the study methodology). With results from these data, a second round of BERTopic analysis was run on the initial 10 topics using a 2-gram BERTopic analysis, and the output topic clusters were reviewed for a final set of 4 clusters that were selected due to their high relevance to *hikikomori* topics. Before manual annotation, we reverted the cleaned posts to their original text with punctuation and stop words to ensure complete comprehension of each post as initially posted. The top 100 tweets with the most interactions from users within the 4 relevant clusters were then selected for manual annotation.

XSL•FO
RenderX

Figure 1. Inclusion criteria and study methodology. BERT: Bidirectional Encoder Representations From Transformers.

Qualitative Content Analysis

The objective of this study was to conduct an in-depth analysis of themes associated with self-reported firsthand and secondhand experiences with *hikikomori* as expressed by Japanese-language Twitter users. For the purpose of study analysis, we relied solely on self-reported *hikikomori* experiences perceived by users and those who observed or interacted with individuals who perceived that they were experiencing *hikikomori* rather than reported verified clinical diagnoses. Hence, there may be variation in the clinical definition of *hikikomori* and self-reported *hikikomori* experiences detected in this study. Our content analysis focused on detecting themes related to firsthand or secondhand knowledge, attitudes, and experiences related to *hikikomori* syndrome or associated characteristics of severe social withdrawal. To classify the content of the collected tweets following topic modeling and topic cluster selection, 2 coders who were native Japanese speakers (the first and second authors, MAU and HB) first independently used a binary coding approach to identify tweets that were relevant to the study aims and excluded tweets that did not fall under the criteria of *hikikomori* syndrome knowledge, attitudes, or experiences self-reported by Twitter users (eg, discussions related to other health or psychological conditions, news articles, statistics or opinions about *hikikomori*, and other topics that used the *hikikomori* term but were not related to the syndrome, hereinafter referred to as *noise*). The primary focus of this study was to identify tweets that met the following conditions: (1) were posted by a Twitter account that appeared to be an individual account (eg, not an organizational, news, or botlike account); (2) self-reported firsthand knowledge of, attitudes toward, or experiences with *hikikomori* syndrome; or (3) self-reported secondhand knowledge of a friend, family member, caregiver, or other social contact that experienced *hikikomori* syndrome.

Discussion of *hikikomori* syndrome or related topics (such as “不登校” or “ニート,” which translate to prolonged absence from school or work in English) in the post content, along with pronouns (such as “僕,” “私,” and “俺,” which translate to *I* or first-person pronouns in English, or “彼,” “彼女,” and “あの子/子供,” which translate to *him* or *her*, *that* or *my child*, or second-person pronouns in English) or other form of reference to the user themselves, signaled relevance as a firsthand or secondhand account. After applying this binary coding scheme for inclusion and exclusion, we then used a general inductive coding approach to conduct in-depth qualitative coding of all relevant tweets selected (hereinafter referred to as *signal tweets*). First, a sample of signal tweets were inductively coded by MAU

XSL•FO
RenderX

and HB, and notes were taken on the general themes of posts, from which an initial code list was created focusing on specific *hikikomori* experiences, behaviors, and societal factors associated with *hikikomori* syndrome. Next, formal coding of all signal tweets was conducted using refined codes and developed subcodes. Finally, MAU and HB reviewed the final coded dataset, and the authors reconciled differences in code definitions and application with senior author TKM, also a native Japanese speaker. MAU and HB coded all posts independently and achieved high intercoder reliability for Twitter thematic classification (Cohen κ=0.95).

On the basis of the content of the collected tweets, all detected themes were classified into three major themes: (1) clinical symptoms, with anxiety (“不安障害” and “パニック障害”), social isolation (“社会的孤立” and “ぼっち”), depression (“うつ病”), self-harm (“死にたい,” “リスカ,” and “自殺”), and developmental and learning disorders (“発達障害” and “学習障害”) as subthemes; (2) social determinants, with school (“不登校”) and work (“ニート”) as subthemes; and (3) awareness, with 1 subtheme detected, education. Descriptive statistics of data characteristics and distribution of the volume of topics coded were also carried out.

Topic Interaction Analysis

To further analyze the levels of user interactivity with different topics related to *hikikomori* experiences self-reported by Japanese-speaking Twitter users, we also examined the volume of users’ interaction behavior for all signal tweets. The interactivity with tweets was determined using the number of likes, retweets, comments, and favorites for the tweets analyzed.

Ethical Considerations

This study was exempt from institutional review board approval in accordance with the Common Rule as all data were publicly available and any user-generated data did not include individually identifiable information, and the results are paraphrased and deidentified.

Results

Overview

A total of 2,057,884 tweets were collected from Twitter from February 13, 2009, to June 23, 2023 (n=2,018,822, 98.1% tweets in Japanese and n=39,062, 1.9% tweets in English), based on the method of data collection used. After the exclusion of English-language tweets and limiting our analysis to a recent 2-year period (to examine the more recent discourse concerning *hikikomori* and discussions centered on the general time frame of the COVID-19 pandemic), 18.43% (379,265/2,057,884) of the tweets in Japanese from January 2021 to January 2023 were included for full analysis. Our results are organized into a description of the output topics selected and the qualitative content analysis of specific tweets in each selected cluster.

Topic Selection and Features

The initial 10 topics selected after the first round of BERT analysis all had overlapping themes of mental health and withdrawal from society and high frequency of *hikikomori*-related terms. Frequently mentioned terms included a variation of the term *hikikomori* (“ひきこもり” or “引きこもり”); words associated with mental health conditions such as depression (“うつ病”); and other related terms associated with being socially isolated, such as not being able to go to school (“不登校”) or work (“ニート”), which provided a preliminary indication that the cluster included conversational groupings related to *hikikomori* behavior and user perceptions. Other terms identified included *hikikomori*-related services or lifestyle, such as unconventional schooling methods (“free school” [“フリースクール”]), or topics such as gaming, gaming livestreams (“ゲーム 実況”), or web-based platforms (eg, “YouTube”) that were suspected as also indicating a *hikikomori* lifestyle. In addition, the presence of more colloquial or casual terms was thought to be more associated with firsthand and secondhand accounts. Following the second round of BERTopic analysis, all *hikikomori*-related themes appeared to be categorized into 1 of the 4 topic clusters selected for the final analysis (topic 1, topic 7, topic 11, and topic 14).

Final Topics for Manual Annotation

The first topic selected as output using BERTopic (topic 1) was selected due the frequency of words such as “お悩み相談” (“consulting for advice”), “話したい” (“want to talk”), and “不登校さんとがりたい” (“seeking connection with someone unable to go to school”), which indicate that tweets in the cluster had a focus on seeking help or connections within the community of those with similar experiences. Phrases such as “必ず返信します” (“I will definitely reply”) suggest the practical uses of Twitter as a platform to encourage and facilitate user interaction. Words such as “フリースクール” (schools dedicated to children who fail to fit into conventional school systems in Japan) and “カウンセリング” (“counseling” or “therapy”) allude to discussion of the services that are available for those experiencing *hikikomori*, including “精神疾患” (“psychological disorder”) and “発達障害” (“developmental disorder”), which further suggests that there is discussion of related disorders and *hikikomori*’s associated impacts. Although there were many possible subtopics in the cluster, there was an overall emphasis on seeking help and exchange of information about the syndrome.

Our second topic selected (topic 7) was focused on mental health, containing topics such as depression (“うつ病”) and suicide (“‘死にたい”), as well as other words or ideas that are closely related, such as bullying (“いじめ”) or feelings of uncertainty or mental instability (“不安”). Words in the cluster were collectively pessimistic or had negative connotations. Phrases such as “どうでもいい報告をする” (“will report something of no use”) may indicate that Twitter users in this cluster of tweets feel as if their words have little impact or may be meaningless, which is in concordance with the overall topic of depression and mental health. This cluster contained tweets related to escaping reality and searching for a place to cope, which indicates that platforms such as Twitter may serve as a conversation space for those who are experiencing *hikikomori* syndrome and other related mental health disorders.

The third topic selected (topic 11) centered on secondhand accounts of *hikikomori* experience, most of which came from parents or guardians of youths or minors experiencing “不登校

XSL•FO
RenderX

の親” (“parents of child unable to go to school or hikikomori”). Words in the cluster such as “いじめ” (“bullying”) and “子育て” (“raising children”) indicate caregivers’ concerns about their children regarding their experiences. This cluster is also characterized by a large portion of keywords related to an unwillingness of youth experiencing *hikikomori* to go to school (“学校行きたくない”), which aligns with the social isolation factor that characterizes *hikikomori* syndrome, suggesting the very closely interlinked ideas of *hikikomori* syndrome and “不登校” (“inability to go to school”). More general terms such as “中学生” (“middle schooler”) or “小学生” (“elementary schooler”) that were included in the cluster suggest that education and school are main topics of discussion and indicate at what grade levels children may be first experiencing *hikikomori* syndrome.

The final topic selected (topic 14) was similar to topic 11 in that it also had a focus on caregivers of youth experiencing *hikikomori*. Many similar words, such as “不登校の親” (“parent of a child unable to go to school”) and “子育て” (“raising children”), were also included in this cluster. However, topic 14 had a more specific focus on solutions to struggles, including alternatives to public school—indicated by words such as “フリースクール” (schools dedicated to children who fail to fit into conventional school systems in Japan) and “家庭教師” (“home or private tutoring”). In addition, words such as “メンタルヘルス” (“mental health”) suggested more discussion and awareness associated with *hikikomori* syndrome. Overall, this cluster highlighted the caregivers’ crucial role as the connection between those with *hikikomori* syndrome and the outside world through platforms such as Twitter, discussion and advocacy, and seeking of opportunities for support and services.

Content Analysis

After the initial round of BERTopic analysis, 10 topic clusters (n=133,548 tweets) were selected as relevant to the study aims and underwent an additional round of BERTopic analysis. Following the second round of running BERTopic, 4 topic clusters (n=33,287 tweets from 6403 unique users) were determined to be relevant to the study aims. From these, the top 100 tweets with the most engagement (measured using the sum of the likes, comments, and retweets) from each of the relevant 4 topics (n=400) were extracted and manually annotated for inclusion or exclusion, of which 37% (148/400) of tweets from 89 unique users were identified as relevant to *hikikomori* experiences. Of these 148 relevant tweets, 71 (48%) were identified as firsthand accounts (eg, individuals who currently had or had recently had direct experience with *hikikomori* syndrome), and 77 (52%) were identified as secondhand accounts (eg, parents or guardians of individuals with *hikikomori* syndrome who often lived in the same household). Our qualitative analysis and inductive coding approach derived 8 topics based on our 3 parent categories. All the detected topics were first classified into the 3 parent domains: clinical symptoms (58/148, 39.2%), social determinants (111/148, 75%), and awareness (33/148, 22.3%; see Table 1 for a description and example tweets of the themes and subthemes).

Posts identified within the clinical symptoms domain were characterized by discussions related to explicit or implicit descriptions or mentions of mental health conditions or symptoms related to *hikikomori* syndrome, including both firsthand accounts (52/58, 90%) and secondhand accounts (6/58, 10%). Within this parent domain, frequently discussed symptoms included anxiety (2/58, 3%), social isolation (32/58, 55%), and depression (24/58, 41%). These subthemes represent symptomology most commonly associated with *hikikomori* syndrome. However, additional subthemes within this domain included self-harm (7/58, 12%) and developmental and learning disorders (3/58, 5%) mentioned and discussed alongside *hikikomori* syndrome, suggesting that these other disorders and symptoms may be additional or emerging symptoms associated with *hikikomori*. Frequent examples of posts within the social isolation subtheme included a stated desire for community support, friends, or others with similar experiences on the platform alongside mentions of their physical and social isolation (eg, isolating within their home). For example, users sought friendships with like-minded individuals, often asking to connect with those within a specific age range (eg, “中学生” [“middle schooler”]) or someone with a particular experience (eg, “不登校” [“someone unable to go to school”]). Within the subtheme of depression, individuals often used the platform to rant or openly vent about their depressive symptoms and as a place of expression. Tweets within this subtheme were more of a snapshot of an individual’s emotions rather than a recollection of an event or informational content. These tweets often included the hashtag “#うつ病” (“depression”). Self-harm had overlap with our depression subtheme but diverged in its explicit mentions of self-harm through suicide or wrist cutting. Tweets frequently included the hashtag “#死にたい” (“want to die”). Our final subtheme, developmental and learning disorders, was frequently mentioned specifically by caregivers. Disorders were cited as factors that led to the *hikikomori* lifestyle or the inability to go to school as conditions accompanying *hikikomori* syndrome or as hindrances to daily life. Other disorders that are diagnostically unrelated were also mentioned alongside *hikikomori* syndrome. Tweets within this subtheme frequently included the hashtags “＃発達障害” (“developmental disorder”) and “#学習障害” (“learning disability”).

Table 1. Explanation and paraphrased examples of the identified hikikomori parent domains and topic subcodes detected on Twitter generated from content analysis (N=148).

Parent domain and subtheme	Subtheme description	Example tweet (original+translation)	Tweets, n (%)
Clinical symptoms			58 (39.2)
Anxiety	Content that describes anxious tendencies or uses terms that relate to them (ie, 不安 or "anxious")	• 不安が増す。("Anxious thoughts are increasing.") • 何に追われてるのかわからないが、 • お金、将来、健康 ("I don't know what is stressing me out, but money, future, health") • 家にじっとしているともういてもたってもいられなくなる。。("If I stay at home, I won't be able to sit still.") • 読書やテレビを観ても頭に入らない。("I can't focus when I read or watch TV.") • 参ってます。("I'm exhausted.") • #鬱 #うつ病 #適応障害 #パニック障害 #不安障害 #不安 #人間関係 #心療内科 #孤独 #ひきこもり #休職 #会社関係 ("#Depressed #Depression #Adjustment disorder #Panic disorder #Anxiety disorder #Anxiety #Human relations #Psychotherapy #Loneliness #Hikikomori #Leave of employment #Co-worker relations")	2 (1.4)
Social isolation	Content that describes social isolation as part of the user's lifestyle	• 休職して孤独な年末年始を目前に("Taking a leave of absence and facing the lonely New Year holidays") • 家のものを断捨離した ("I got rid of things at home") • 少しスッキリした社宅の中 ("Inside the slightly empty company housing") • 少し気分が晴れた ("I feel a little better")	32 (21.6)
Depression	Content that displays depressive thoughts or episodes that reflect a nonprogressive and pessimistic mindset of the user	• 買いたいもの、欲しいものなんて買えないし、バイトする気力は無いし、そもそも生きたい理由もないから、何もできない。("I can't buy anything I want, I don't have the energy to work part-time, and I have no reason to want to live in the first place, so I can't do anything.") • 生きているだけで惨めな思いをする。("Just being alive makes me feel miserable.") • 頑張れないし、苦しいし、生きていても迷惑かけるだけだから死にたいって思うのは「甘え」なのだろうか。("Am I acting like a spoiled child to think that I want to die because I can't do my best, it's painful, and even if I live I'll only cause trouble?") • #ニート #ひきこもり #死にたい ("#Not in Education, Employment, or Training (NEET) #Hikikomori #Want to die")	24 (16.2)
Self-harm	Content that includes mentions or descriptions of self-harm and suicide	• 新品のカミソリ気持ちよすぎだろ ("The brand-new razor blade feels so good ") • 新品しか勝たん. ("New blades for the win .") • #自傷行為 #不登校 #od ("#Self-harm #Not going to school #od") • #不登校と繋がりたい ("#I want to connect with school truants") • #リスカ #アムカ #レグカ ("#Wrist cutting #Arm cutting #Leg cutting") • #病み垢 #病み垢女子 ("#Account characterized by mental sickness #Girl with account characterized by mental sickness") • #病み垢女子さんと繋がりたい ("#Want to connect with girls with accounts characterized by mental sickness") • #病み垢さんと繋がりたい ("#Want to connect with people with accounts characterized by mental sickness")	7 (4.7)
Developmental and learning disorders	Content that includes the mention of other developmental and learning disorders alongside "hikikomori" syndrome	• #不登校 なのにも動じないで普通に接してくれるのはとても有難いんだけど #非同期発達 の事は、特に勉強面に関しては言い辛いから一寸困る。こちらは正直に話しても良いんだけどホントに時々態度急変する人が居るから面倒臭くて試す気にはなれない。 • "I'm very grateful that you don't get upset and treat me normally even though I'm not going to school, but it's a bit difficult to talk about #asynchronous development, especially when it comes to studying. I can be honest about this, but there are some people whose behavior changes suddenly after finding out, so I find it annoying and I don't feel like risking it."	3 (2)

Parent domain and subtheme	Subtheme description	Example tweet (original+translation)	Tweets, n (%)
Social determinants			111 (75)
School	Content that includes mentions of school and education, often through the act of missing school or unconventional alternatives to public school	• 娘がチャレンジの問題でつまずいて癇癪。学校行ってる子達と比べたら圧倒的に解いてる問題数が違うからすぐにつまずく。適室での勉強も家庭教師も拒否。今自室で『自分だけの力でやってみせる』ってヤケになって勉強しに行った。もう限界でしょうよ. どうすりゃいいの. (“My daughter stumbles over a challenging problem and has a tantrum. Compared to kids who go to school, the number of problems she solves is greatly less, so it’s easy to get stuck. She refuses to study in a proper room or have a private tutor. She just said, ‘I’ll do it on my own’ and went to study in her room. It’s probably at its limit. What should I do.”) • #不登校 #不登校の親 (“#Not going to school #Parents of children not going to school”)	103 (69.6)
Work	Content that includes mentions of work, often through the act of missing or quitting work	• 親から「ウーバーイーツでも何でもやれ」「死に物狂いでやるしかないだろう」と言われた。(“My parents told me, ‘Find a job, work for Uber Eats if you need to’ and ‘Work as if your life depends on it.’”) • 仕事するために”死に物狂い”になる必要がある状況って何だろう。(“In what situation would you need to be ‘desperate’ to do your job”) • 仕事するために生きているわけでもないし。(“I don’t live to work.”) • 親から何か言われるたび、死んだほうがマシだとしか思えない。(“Every time my parents say something to me, all I can think is that I would be better off dead.”) • #ニート #ひきこもり #死にたい (“#NEET #hikikomori #Want to die”)	8 (5.4)
Awareness			33 (22.3)
Education	Content that includes active forms of providing education about “hikikomori” syndrome to the public or active advocacy	• #不登校#ひきこもり #ニート 今振り返れば。今の自分なら。そう言えるくらいに全部の経験が今に繋がる。今どこかで悩んでいるおかあさんへ。当事者さんへ。あなたは大丈夫。ひとりじゃない。あなたはあなた。他の誰かは他の誰か。みんな違っていいんだよ。 • “#Not going to school #Hikikomori #NEET Looking back now, I can say that all of my experiences have led me to where I am today. Dear mothers and other people who are worried right now. You are ok. You are not alone. You are you. Someone else is someone else. It’s okay for everyone to be different.”	3 (2)

The social determinants parent domain was mentioned in 75% (111/148) of the tweets relevant to *hikikomori* experiences. Mentions of school or being “不登校” (“not going to school”) were common (103/111, 92.8%), reflecting the younger demographic of those posting about or experiencing *hikikomori* syndrome on Twitter. Although the age of users is difficult to determine, many individuals who sought out a human connection or social interaction on the platform requested relationships within an age range (eg, middle schoolers or high schoolers). Topics such as the lack of friendship due to their isolated lifestyle or their inability to go to school were discussed. Caregivers on Twitter discussing *hikikomori* syndrome were mainly parents of youth who were also “不登校” (“not going to school”). In addition, these caregivers displayed a sense of responsibility to improve their children’s lives or ease their difficulties and pain, observed through their active participation in seeking help. As a result, there were many secondhand experiences or caregiver community users detected in these tweets (71/111, 64%). Topics discussed included alternative education opportunities (eg, “フリースクール” [schools dedicated to children who fail to fit into conventional school systems in Japan] or “家庭教師” [“home or private tutoring”]), parenting philosophies, and specific experiences and advice regarding *hikikomori* syndrome. Less common were mentions of work and *hikikomori* (8/111, 7.2%). Tweets identified within this subtheme expressed an even greater disconnect from society and personal accounts of struggling to come to terms with lack of financial independence. Overall, within this parent domain, we found that *hikikomori* syndrome is heavily intertwined with the ideas of “ニート” (“not going to work”) and “不登校” (“not going to school”) in Japanese society. Even when tweet content alluded to a *hikikomori* lifestyle, many preferred the terms “ニート” and “不登校” (“not going to work” and “not going to school”) when self-identifying over explicitly identifying

XSL•FO
RenderX

themselves as having *hikikomori* syndrome. The hashtags "#ニート" and "#不登校" were observed frequently with or even synonymously to *hikikomori* ("#引きこもり" or "#ひきこもり").

Within the awareness parent domain, individuals sought to reduce stigma regarding *hikikomori* syndrome by spreading awareness about the condition (33/148, 22.3%). Users spread awareness through Twitter primarily in 2 ways. Some tweets portrayed the syndrome positively by clearing misconceptions that previously created apprehensiveness toward *hikikomori* syndrome or by drawing attention to the benefits of the lifestyle (eg, having less disputes between family members and, consequently, having a more peaceful and connected family life in certain circumstances). Other tweets highlighted the negative attitudes toward the syndrome and aimed to reduce stigma by portraying stigmatization of *hikikomori* in a negative context (eg, explaining how a friend's negative comments were morally unacceptable). This was frequently observed through users recalling an experience in which an individual experiencing *hikikomori* syndrome or their caregivers faced shame for their condition. Tweets were not always targeted toward the public and, instead, aimed to reduce internal shame of the syndrome by addressing users with similar experiences. Tweets within the education subtheme (3/33, 9%) were characterized by users providing knowledge to the public through digital flyers, meetings, or other active forms of creating awareness, directly addressing their audience in the process. Tweets within this subtheme were only posted by caregivers and in secondhand accounts as explicit advocacy and education often requires contact with the public. Although it was uncommon, some caregivers used the platform to educate and act in the role of mediator between the isolated population and the uninformed public.

In general, those experiencing *hikikomori* and their caregivers used Twitter to either share experiences and opinions with the public through 1-way communication (personal anecdotes, emotional ranting, and advocacy) or increase social interaction and discussion through 2-way communication (seeking social support and seeking and giving advice). Through 1-way communication, those experiencing *hikikomori* disclosed important and often personal information on their lifestyle or used the platform as a means to discuss and cope with their struggles. Caregivers often shared their own experiences with family members with *hikikomori* syndrome and also worked to directly reduce stigma. Through 2-way communication, those experiencing *hikikomori* found like-minded individuals on the web to connect with. Caregivers also exchanged advice and information to better support individuals experiencing *hikikomori*. We found more 1-way communication (53/71, 75% of firsthand accounts and 54/77, 70% of secondhand accounts) than 2-way communication in the tweets analyzed. However, the audience and motive of the tweets were often unspecified.

Discussion

Principal Findings

This study collected and analyzed 2,018,822 tweets with terms related to *hikikomori* syndrome, a form of severe social withdrawal prevalent in Japan, and after conducting data filtering for more recent posts posted between January 2021 and January 2023 and topic modeling for detection of prevalent themes, we found both first- and secondhand experiences reported among Japanese-language tweets (148/2,018,822, 0.01%) from 89 unique users. Among our sample, we found that 48% (71/148) of tweets discussing their experiences with *hikikomori* syndrome were firsthand accounts of the challenges associated with their daily lives, whereas 52% (77/148) were identified as secondhand accounts mainly from caregivers. Within both first- and secondhand reports, the parent categories identified were clinical symptoms, social determinants, and awareness.

Within the 3 parent domains, we found 8 subthemes, which included users describing firsthand and secondhand experiences with *hikikomori* symptoms, including anxiety, depression, social isolation, self-harm, and developmental disorders, as well as discussion related to missing school or work, a commonly reported manifestation of *hikikomori* [1]. Twitter users in this study also shared advocacy and educational awareness related to the syndrome and sought out connections with other web-based users. Similarly to previous research, this study found a variety of topics. Common use of personal anecdotes and other detected topics such as social support, exchange of advice, and stigma are in line with and further support existing research findings, emphasizing the potential value of social listening–related *hikikomori* discourse on social media platforms where *hikikomori* communities interact [22]. Our findings provide additional novel context by focusing on first- and secondhand experiences of the syndrome to better characterize lived experiences with *hikikomori*. Previous studies have identified topics such as marketing, employment and educational opportunities, and medical and science topics related to the syndrome, which were excluded from this study [22,23].

This study provides additional context to the *hikikomori* literature and provides the first social media–based study to characterize web-based discussions from both the first- and secondhand perspectives in the Japanese language, specifically following the COVID-19 pandemic. Of the social media studies that have characterized lived experiences with *hikikomori*, some have focused on *hikikomori* in Western societies, including European countries, in which individuals who directly experience *hikikomori* were the most active users, in contrast to this study, in which secondhand posts were the most commonly detected overall (eg, caregivers or friends of those with *hikikomori* syndrome) [32]. While COVID-19 restrictions resulted in mandated social isolation to different degrees for people worldwide, there may have been more visibility of *hikikomori* symptoms by caregivers that may not have been otherwise observed before many of the public health restrictions during the pandemic. In turn, caregivers may have turned to social media to connect with others, seek advice about *hikikomori*, or spread awareness of the syndrome.

While our study found more secondhand experiences with *hikikomori* overall, within our clinical symptoms parent topic, we found an overwhelming majority of firsthand reporting of *hikikomori* (52/58, 90%). These findings may indicate that, when an individual is struggling with *hikikomori*, they are more likely to self-report their struggles with the syndrome and its

XSL•FO
RenderX

associated symptoms on the web. Concerningly, as detected in this study, individuals may take to web-based platforms to report more severe symptoms and mental health struggles, such as suicidal ideation [33]. However, social media has increasingly represented a valuable way to detect depression and suicidal ideation and can provide rapid data for policy-level decisions, especially given the rise of mental health conditions during and after the pandemic [33]. As such, this finding may also represent shifting ideas and definitions regarding *hikikomori*, especially after the COVID-19 pandemic, a period characterized by social isolation, remote education, and increasing mental health concerns [26]. Furthermore, firsthand users detected in this study may take to web-based platforms as a way to discuss their own experiences and self-report *hikikomori*-related symptoms but appear to engage in less education, advocacy, or awareness raising compared to those with secondhand experiences based on our observations.

Platforms such as Twitter may be an advantageous and comfortable way for those with *hikikomori* syndrome to interact with others while in a lifestyle that lacks social interaction, especially during the mandated social distancing measures that aligned with the study period. Simultaneously, the results provide updated insights into the lives of those with *hikikomori* syndrome and others who support them, as well as into direct advocacy by those who are affected. The findings indicate that access to information on this syndrome through social media platforms can increase access to other individuals and broader online communities experiencing the syndrome, possibly facilitated by semianonymous and web-based conversations, which may otherwise be inhibited by physical barriers due to the isolating nature of *hikikomori*. By leveraging platforms such as Twitter, greater interactions within the community can potentially reduce internal stigma and shame, whereas greater interactions with the public can reduce external stigma toward the syndrome as a whole [34]. In addition, open discussion about experiences and resources available, both within the community and through interactions with the public, could lead to greater accessibility to those resources and more awareness and acceptance.

Limitations

This study has certain limitations. First, it only evaluated data from publicly available content on Twitter and limited the analysis to Japanese-language tweets and tweets that were in both Japanese and English, which is not representative of general social media *hikikomori*-related discourse, including that occurring on other platforms such as Facebook, Reddit, TikTok, and Instagram. Hence, this study may fail to capture posts from individuals who have additional privacy settings or engage in conversations via private or direct messages due to the stigmatization of mental health issues. Furthermore, this study only analyzed tweets posted by users and not comments or other interactions between Twitter users in response to a tweet, which could have yielded additional discussion related to *hikikomori*. In addition, our period of data collection and analysis coincided with the COVID-19 pandemic, which significantly impacted individuals' way of life and required social isolation. Hence, the volume and nature of *hikikomori* discussions on the web may have also been driven by the COVID-19 restrictions during the study period. This study likely underreported the total amount of *hikikomori*-related content within the dataset as we only coded tweets that were the most highly engaged with within selected topic clusters. This approach streamlines manual coding and allows for more efficient detection of relevant conversations but may exclude tweets that have low engagement. Furthermore, this study may have oversampled what is considered clinical *hikikomori* discussions due to variation in the colloquial meaning of *hikikomori*, the potential expansion of *hikikomori* to refer to less severe symptoms, and the reliance on self-reported accounts from web-based users and their perception of their or someone else's experience with *hikikomori*. Hence, it is crucial to acknowledge that this study's findings are specific to a subset of *hikikomori* accounts and content—those who consider themselves as experiencing *hikikomori* first- or secondhand. As such, it may not capture the diversity of *hikikomori* behaviors and attitudes and lacks generalizability to the overall population of those who experience it. In addition, although Twitter offers users a significant degree of anonymity through features such as customizable usernames and the option to create throwaway accounts for sensitive discussions, self-reported measures remain susceptible to recall bias and social desirability bias, which could lead to over- or underreporting of behaviors. Thus, tweets coded as *hikikomori* may in some instances be less representative of the clinical condition and more associated with the casual use of the term to describe non-*hikikomori* symptoms or may more broadly reflect the collective understanding of *hikikomori* as a concept in Japanese culture by those who do not actually have the condition from a clinical context. Future studies should explore multi-platform analysis for *hikikomori*-related discussions, combine social media data with other data sources (eg, focus groups and surveys), and use other data science approaches (eg, supervised machine learning and large language models) to better characterize *hikikomori* changes over a longer period both before and after the pandemic.

Conclusions

Understanding culturally specific self-reported symptomology through social media studies may offer insights into the convergence and divergence of cross-national *hikikomori* experiences. In addition, commonalities in experiences and rhetoric provide insights into the Japanese public's view of *hikikomori* and its prevalence in Japanese society. The findings of this study also have potential clinical implications. As *hikikomori* is increasingly recognized as a global concern, clinicians may look to web-based platforms and discussion forums to understand modern manifestations of the syndrome and the collective understanding of the concept in different cultural contexts (both in Japan and other cultures experiencing *hikikomori*), especially as a standardized definition and criteria are evolving [4]. This study may also provide additional evidence that online support groups may be well received among those with *hikikomori* and could provide clues on how to help relieve adverse experiences associated with social withdrawal as well as provide social support for those caring for someone with *hikikomori* [32]. These results may also justify the need to increase telehealth consultations in the post–COVID-19 era regarding *hikikomori* screening and possible diagnosis. However, increasing participation in digital care and support

XSL•FO
RenderX

opportunities for patients with *hikikomori* syndrome should be afforded careful consideration to ensure that that same technology does not facilitate further social isolation if not used correctly or in a culturally appropriate manner [35,36].

Abstract

Background: The advent of the internet has transformed the landscape of health information acquisition and sharing. Reddit has become a hub for such activities, such as the subreddit r/medical_advice, affecting patients' knowledge and decision-making. While the popularity of these platforms is recognized, research into the interactions and content within these communities remains sparse. Understanding the dynamics of these platforms is crucial for improving online health information quality.

Objective: This study aims to quantitatively analyze the subreddit r/medical_advice to characterize the medical questions posed and the demographics of individuals providing answers. Insights into the subreddit's user engagement, information-seeking behavior, and the quality of shared information will contribute to the existing body of literature on health information seeking in the digital era.

Methods: A cross-sectional study was conducted, examining all posts and top comments from r/medical_advice since its creation on October 1, 2011. Data were collected on March 2, 2023, from pushhift.io, and the analysis included post and author flairs, scores, and engagement metrics. Statistical analyses were performed using RStudio and GraphPad Prism 9.0.

Results: From October 2011 to March 2023, a total of 201,680 posts and 721,882 comments were analyzed. After excluding autogenerated posts and comments, 194,678 posts and 528,383 comments remained for analysis. A total of 41% (77,529/194,678) of posts had no user flairs, while only 0.1% (108/194,678) of posts were made by verified medical professionals. The average engagement per post was a score of 2 (SD 7.03) and 3.32 (SD 4.89) comments. In period 2, urgent questions and those with level-10 pain reported higher engagement, with significant differences in scores and comments based on flair type (P<.001). Period 3 saw the highest engagement in posts related to pregnancy and the lowest in posts about bones, joints, or ligaments. Media inclusion significantly increased engagement, with video posts receiving the highest interaction (P<.001).

Conclusions: The study reveals a significant engagement with r/medical_advice, with user interactions influenced by the type of query and the inclusion of visual media. High engagement with posts about pregnancy and urgent medical queries reflects a focused public interest and the subreddit's role as a preliminary health information resource. The predominance of nonverified medical professionals providing information highlights a shift toward community-based knowledge exchange, though it raises questions about the reliability of the information. Future research should explore cross-platform behaviors and the impact of misinformation on public health. Effective moderation and the involvement of verified medical professionals are recommended to enhance the subreddit's role as a reliable health information resource.

(JMIR Infodemiology 2025;5:e56116) doi:10.2196/56116

KEYWORDS

online health information; medical advice; Reddit; r/medical_advice; health information–seeking behavior; user-generated content; subreddits; patient education; virtual environments; information quality; social media; medical problem; quantitative analyses; cross-sectional study; user interactions; online health; decision-making; social news; health information

XSL•FO

Introduction

The internet has significantly impacted how individuals access and share health-related information. Online health information–seeking behavior has been a growing area of interest in the medical literature, given its potential impact on patient knowledge, decision-making, and outcomes [1]. As a result, the quality and accuracy of health information shared on the internet have been the subject of numerous studies, which have identified both benefits and risks for users [2,3].

Reddit, a social news forum and discussion website, has emerged as a popular platform for health information sharing [4]. Among its topic-specific communities called "subreddits," r/medical_advice has become a prominent online community where users seek and provide advice related to medical conditions, symptoms, and treatments [5]. r/medical_advice stands out not only for its popularity but also for its extensive user engagement compared with other similar online communities. Despite its popularity, there has been limited research examining the content and user interactions within this online community [6]. As the demand for patient education in internet-based environments continues to grow, it is essential to understand the topics discussed on this subreddit to assess the quality of the information provided, as well as the challenges associated with providing accurate and reliable health information in online spaces.

We define information-seeking behavior as the deliberate pursuit of health-related knowledge by individuals, which differs from information sharing (actively providing knowledge to others) and more general health communication (exchanging health-related messages with various purposes). By focusing on r/medical_advice, we specifically examine users seeking preliminary guidance or reassurance before consulting health care professionals. This study addresses three main research questions: (1) What types of medical questions are asked on r/medical_advice? (2) How do different post flairs, pain levels, and inclusion of media relate to user engagement? and (3) How do verified and nonverified medical professionals contribute to the information ecology of r/medical_advice? The findings of this study will contribute to the growing body of literature on health information–seeking behavior in the digital age and help inform potential strategies for improving the quality and utility of online health information.

Methods

Study Design and Data Collection

This cross-sectional study systematically characterized all posts and their top comments from the r/medical_advice subreddit since its inception on October 1, 2011. Data for this investigation were collected on March 2, 2023, using a public resource created by Jason Baumgartner of pushshift.io [7]. Metadata fields collected for posts included subreddit, post ID, title, self-text, post flair, comment score, post score, author, author flair, URL, image, time stamp, and date (Table 1). Flairs are a feature that allows users to add a label or tag to their posts or usernames. Post flairs categorize post content, while user flairs (also referred to as author flairs) can indicate qualifications or expertise in a specific subject. For comments, the collected metadata fields included subreddit, comment content, score, author, author flair, post ID, URL, image, time stamp, and date. Before analysis, we applied data cleaning steps to remove non–user-generated content and posts that did not represent genuine user inquiries such as automated moderation posts, duplicate entries, or advertisements. We used similar criteria for comments to ensure that both posts and comments represented organic user activity.

Table 1. Definition of metadata fields. This table provides definitions for the common metadata fields encountered in the pushshift.io database.

Metadata field	Definition
Subreddit	The name of the specific Reddit community where the post is made
Post ID	A unique identifier assigned to each post in a subreddit
Title	The heading or title of the Reddit post
Self-text	The main body text of the Reddit post
Post flair	A category or tag assigned to a post to indicate its content or topic
Comment score	A numerical value representing the net upvotes and downvotes a comment receives
Post score	A numerical value representing the net upvotes and downvotes a post receives
Author	The username of the individual who created the post
Author flair	A tag or label next to a user's name that indicates their role, expertise, or affiliation
URL	A direct link to the specific Reddit post
Image	Visual content (photo or graphic) attached to a Reddit post
Time stamp	The exact date and time when the post or comment was made
Date	The date when the post was made, formatted as year-month-day

XSL•FO
RenderX

Subreddit Time Periods and Flair Analysis

The analysis of posts was divided into 3 distinct time periods: October 1, 2011, to March 5, 2019 (period 1); March 6, 2019, to July 31, 2022 (period 2); and August 1, 2022, to March 2, 2023 (period 3). This categorization was necessary due to the varying availability of flairs during these periods. Period 1 had no available flairs, whereas period 2 offered flair options based on pain level or question type. In period 3, flairs were organized using a systems-based approach.

The analysis of author flairs was conducted between May 7, 2019, and March 2, 2023, which corresponds to the implementation of author flairs. Throughout the entire time period, user flair options remained consistent. Flairs related to each post, the account that submitted the post, and comments were analyzed.

Definition of Scores

Scores were defined as the net result of upvotes subtracted by downvotes, with a lower limit set at 0. Upvotes and downvotes on Reddit signify agreement, relevance, or perceived quality of a post or comment. A higher score typically indicates greater community acceptance.

Statistical Analysis and Data Visualization

RStudio (Posit) was used for all statistical analyses, while data visualization was conducted using GraphPad Prism 9.0 (Insight Partners).

Data Analysis

The data analysis process involved the calculation of averages and SDs for posts across the 3 time periods. To comprehensively examine the engagement of the subreddit community with the posts, the study considered several factors, including post flair; the presence of images, galleries (multiple images), or videos; and the combined engagement, which was defined as the sum of scores and comments.

A detailed examination of post flair engagement was conducted, comparing engagement across flairs in periods 2 and 3. The Kruskal-Wallis test was initially applied to assess differences in combined engagement, followed by the Dunn test for pairwise comparisons. During period 2, the analysis was segregated into question type (general, urgent, or other) and pain level (no pain, 1-3, 4-6, 7-9, and 10). Since each post could only be assigned a single flair, posts were exclusively categorized based on either question type or pain level.

In period 3, a similar statistical approach was used to compare combined engagement by the type of medical problem. The analysis in this period focused on the systems-based categorization of post flairs, enabling a more targeted investigation of engagement patterns.

Ethical Considerations

Project data were collected from a publicly accessible online forum. No direct interaction with users occurred, and no personally identifiable information was included in the dataset. In accordance with ethical guidelines for internet research, efforts were made to ensure privacy and confidentiality by excluding usernames and any personally identifiable content from the analysis. The use of Reddit data complies with the platform's terms of service, which allow the analysis of public content for research purposes. Institutional review board approval was not required, as this study exclusively analyzed publicly available, anonymized data and did not involve human participant interventions.

Results

Demographics and Flair Distribution

A total of 201,680 posts (Figure 1A) and 721,882 comments (Figure 1B) were collected from October 2011, the inception of the subreddit, through March 2023. After data cleaning to remove nonmedical inquiries and responses, 194,678 posts and 528,383 comments remained for analysis. The top flairs of periods 2 and 3 are shown in Tables 2 and 3, respectively.

Figure 1. Quarterly trends in posts and comments in r/medical_advice. This bar graph displays the (A) number of posts and (B) comments in the r/medical_advice subreddit over time, with each bar representing a quarter of a year on the x-axis. Qtr: quarter.

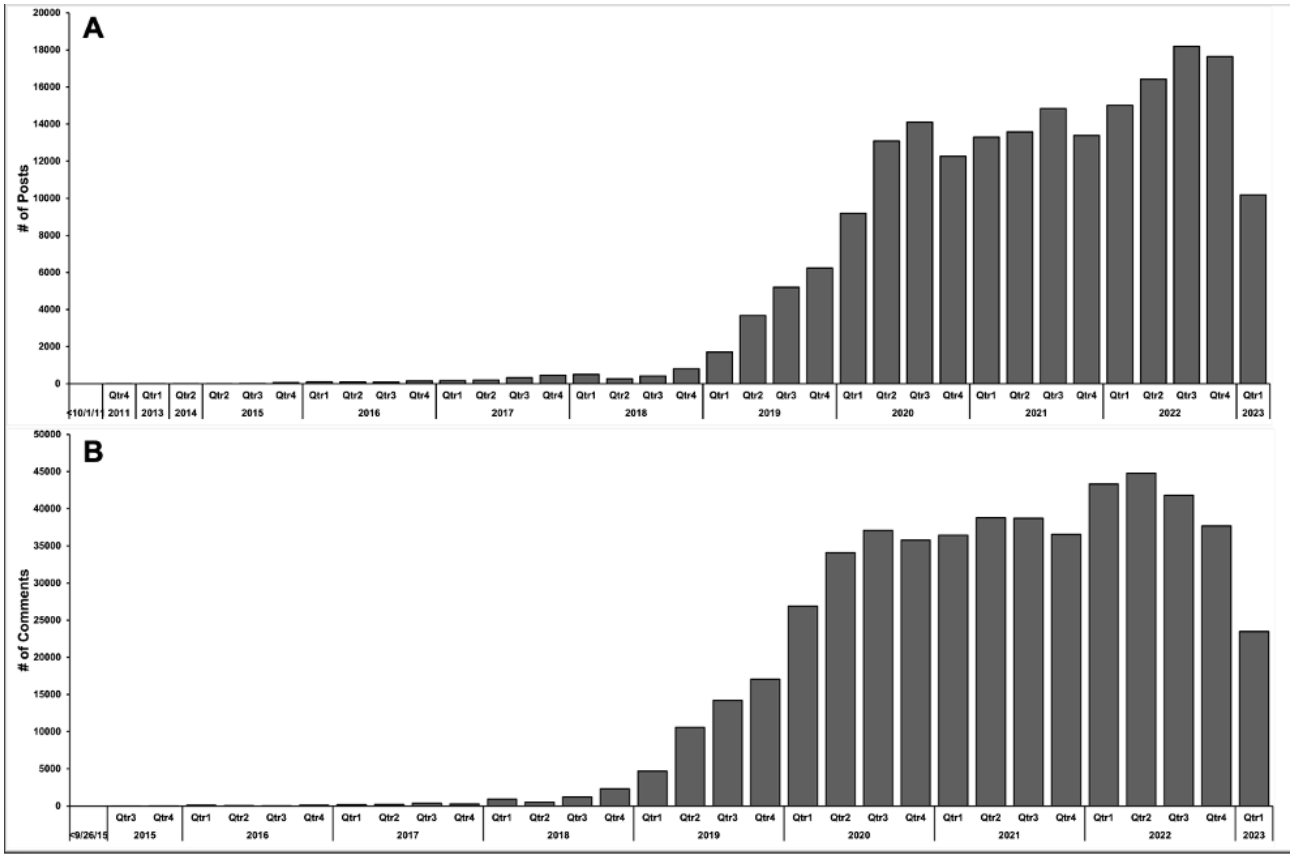

Table 2. Distribution of post flairs in period 2. The table shows the frequency and percentage of post flairs categorized by question type and pain level, illustrating the prevalence of various types of medical questions and reported pain levels in the subreddit during this period.

Post flair type	Post flairs (n=136,486), n (%)
Question type	
General question	50,671 (37.4)
Urgent question	17,739 (13.1)
Other question	6612 (4.9)
Pain level	
No pain	23,844 (17.6)
Levels 1-3	18,337 (13.5)
Levels 4-6	12,252 (9)
Levels 7-9	6055 (4.5)
Level 10	976 (0.7)

XSL•FO
RenderX

Table 3. Distribution of post flairs in period 3. This table presents the frequency and percentage of post flairs across different medical topics during period 3, highlighting the most discussed health issues in the subreddit during this period.

Post flair	Values (n=27,661), n (%)
Skin issues or rashes or freckles or moles	6505 (23.5)
Mouth or gums or throat or cheeks	2648 (9.6)
Genitalia	2486 (9)
Injury	2447 (8.8)
Bones or joints or ligaments	2198 (7.9)
Digestion or stomach or bowels	2179 (7.9)
Illness	2033 (7.3)
Wound care	2015 (7.3)
Medication	1758 (6.4)
Cardiac	1230 (4.4)
Eyes	903 (3.3)
Mental health	741 (2.7)
Parasite concern	264 (1)
Pregnancy	254 (0.9)

User Flair Analysis

Across all time periods, 41% (77,529/194,678) of posts were made by users without user flairs, 42% (81,607/194,678) of posts were made by users who were not verified medical professionals, 18% (35,434/194,678) of posts were made by users who were not verified, and 0.1% (108/194,678) of posts were made by verified medical professionals. The verification process on the subreddit requires the user to upload a picture of their employment badge next to their handwritten username. In other words, 99.9% (194,886/194,691) of the posts were made by Redditors who were not verified medical professionals.

With respect to comments across all three periods, 50% (232,274/528,383) of the comments were made by users tagged "Not a Verified Medical Professional," 39% (183,470/528,383) of the comments were made by users tagged "Users Not Verified," and 12% (55,296/528,383) of the comments were made by medical professionals. Table 4 illustrates the breakdown of medical professionals by profession.

Table 4. Breakdown of medical professionals in comments.

Medical profession	Values (n=55,296), n (%)
Nurses[a]	29,838 (54)
Physicians	11,204 (20.3)
Students[b]	6615 (12)
Emergency medical services personnel[c]	1496 (2.7)
Allied health professionals[d]	962 (1.7)
Medical assistants	468 (0.8)
Midlevel providers[e]	215 (0.4)
Nursing support staff[f]	89 (0.2)
Other (moderators, etc)	4409 (8)

[a]Nurses encompass registered nurses, licensed practical nurses, and licensed vocational nurses.

[b]Students involve medical, nursing, and allied health students.

[c]Emergency medical services personnel consist of paramedics and emergency medical technicians.

[d]Allied health professionals include roles such as respiratory therapists, occupational therapists, physical therapists, and radiologic technologists.

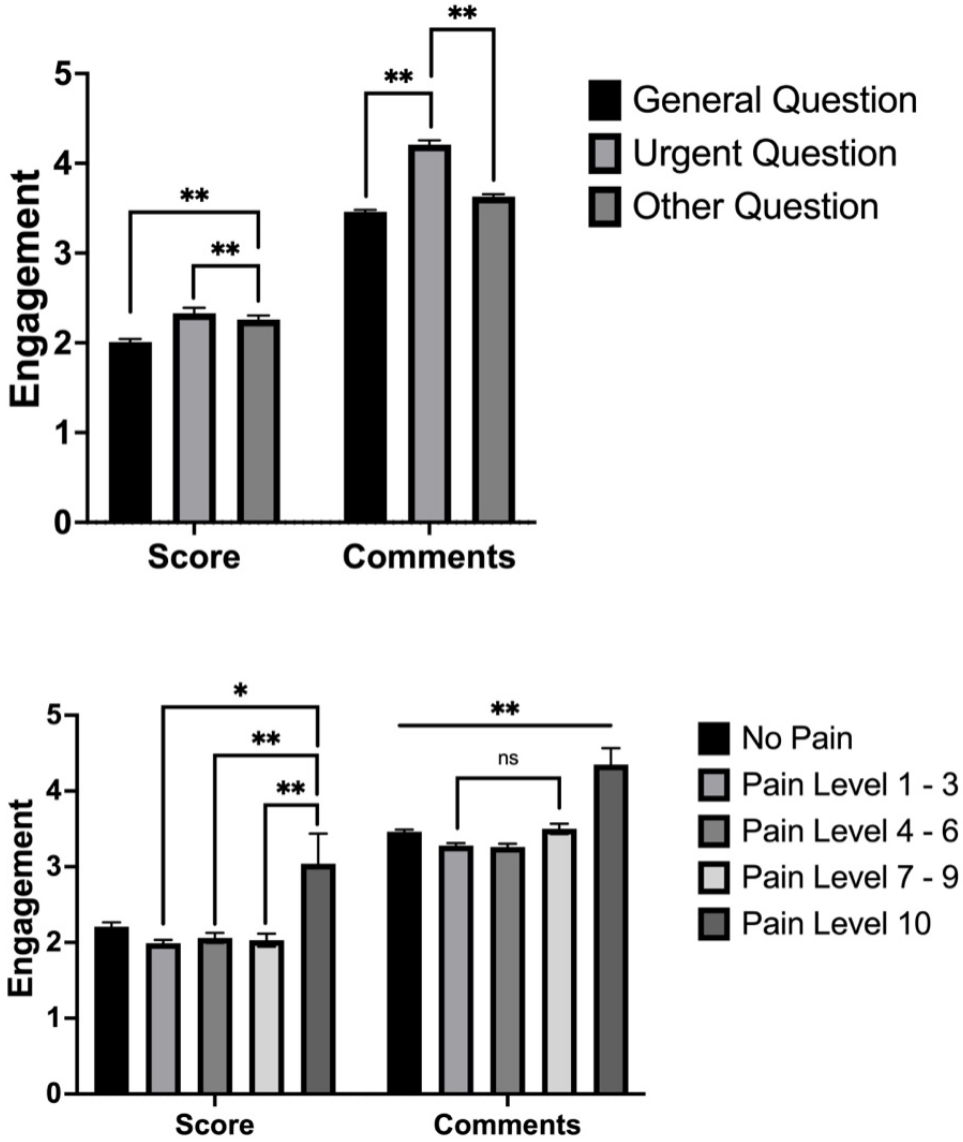
[e]Midlevel providers include nurse practitioners and physician assistants.

[f]Nursing support staff includes certified nursing assistants.

XSL•FO
RenderX

Engagement Analysis

Across all posts and time periods on the subreddit, on average, each post received a score of 2 (SD 7.03; range 0-687) and 3.32 (SD 4.89; range: 0-338) comments. To account for the total engagement level of the subreddit over time, the following averages were calculated for each period: (1) score of 1.38 (SD 0.98) and 2.17 (SD 2.87) comments in period 1; (2) score of 2.14 (SD 7.71) and 3.56 (SD 5.05) comments in period 2; and (3) score of 1.48 (SD 3.83) and 2.50 (SD 4.30) comments in period 3.



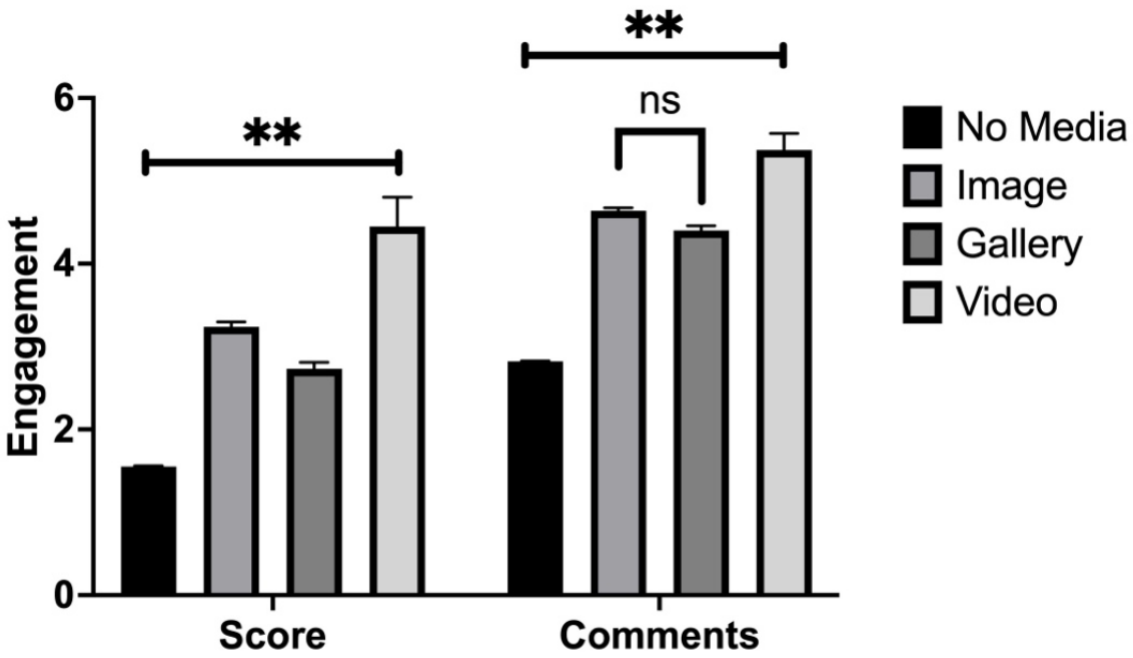
In period 3, posts were divided into system-based flairs. A total of 11,772 posts were removed from the analysis due to the lack of problem-based flairs, leaving 27,661 posts for flair analysis. Engagement, broken down by flair for period 3 is highlighted, is given in Table 5. Posts related to pregnancy had the highest engagement in period 3, while those about bones, joints, or ligaments had the lowest engagement (Figure 2). This pattern was reflected when examining both scores and comments.

Table 5. Engagement by post flair in period 3. This table presents the mean (SD) values of combined engagement (score and comments) for each post flair category during period 3, highlighting the varying levels of engagement across different medical topics within the r/medical_advice subreddit.

Post flair	Combined engagement, mean (SD)	Score, mean (SD)	Comments, mean (SD)
Pregnancy	6.16 (9.18)	1.93 (4.34)	4.23 (5.9)
Wound care	4.60 (9.12)	1.74 (5.53)	2.86 (4.59)
Injury	4.59 (9.97)	1.88 (5.86)	2.71 (5.1)
Parasite concern	4.36 (6.31)	1.51 (2.93)	2.85 (4.23)
Skin issues, rashes, freckles, or moles	4.17 (8.93)	1.60 (4.89)	2.57 (4.58)
Genitalia	4.05 (6.89)	1.42 (3.18)	2.63 (4.32)
Cardiac	3.86 (6.65)	1.34 (2.03)	2.53 (5.01)
Mouth, gums, throat, or cheeks	3.86 (8.13)	1.47 (3.98)	2.40 (4.62)
Illness	3.80 (6.67)	1.39 (2.89)	2.41 (4.46)
Eyes	3.76 (7.41)	1.48 (3.62)	2.28 (4.28)
Mental health	3.65 (5.25)	1.35 (2.66)	2.30 (3.33)
Medication	3.58 (5.09)	1.28 (2.71)	2.30 (3.06)
Digestion, stomach, or bowels	3.45 (4.73)	1.24 (1.97)	2.21 (3.34)
Bones, joints, or ligaments	3.13 (4.34)	1.25 (1.90)	1.88 (2.85)

XSL•FO
RenderX

Figure 2. Engagement analysis by question type and pain level in period 2. This figure presents two separate bar graphs, illustrating the engagement patterns in r/medical_advice during period 2. The top graph displays the engagement by question type, including general question, urgent question, and other question, while the bottom graph shows the engagement by pain level categories (no pain, levels 1-3, levels 4-6, levels 7-9, and level 10). Error bars represent the SEM. Asterisks indicate the level of statistical significance (*P<.05 and **P<.01), with all comparisons in the bottom graph being significant except for the one marked as nonsignificant. These graphs highlight the differences in engagement across various question types and pain levels, shedding light on the patterns of user interaction in the subreddit during period 2. ns: nonsignificant.



Engagement by Media Inclusion

A total of 28% (56,533/201,904) of posts contained media in the form of images or videos. Of these, 20% (39,776/198,830) included a single image, 8% (15,149/189,363) included multiple images, 0.8% (1608) included a video, and 72% (145,147/201,000) did not include any media. Posts that included a single image received, on average, a score of 3.24 (SD 12.03) and 4.64 (SD 6.91) comments. Posts with multiple images received, on average, a score of 2.73 (SD 9.18) and 4.40 (SD 6.80) comments. Posts with a video received, on average, a score of 4.45 (SD 14.10) and 5.37 (SD 7.98) comments (Figure 3).

XSL•FO
RenderX

Figure 3. Engagement by inclusion of media. This bar graph illustrates the engagement of posts based on the type of media the posts include in r/medical_advice during all periods. Gallery means multiple images are included as part of the post. Error bars represent the SEM. Asterisks indicate the level of statistical significance (*P<.05 and **P<.01). ns: nonsignificant.

Posts with any media received, on average, a score of 3.14 (SD 11.41) and 4.60 (SD 6.92) comments, compared with a score 1.55 (SD 4.15) and 2.82 (SD 3.70) comments for posts without any media. Compared with posts without media, those with media received higher engagement (Dunn test; scores P<.001, comments P<.001). There was a significant difference between engagement of videos, multiple images, and a single image (Dunn test; scores P<.001; comments P<.001). Posts with videos received the highest engagement, followed by posts with images, and posts with no media received the least. Furthermore, posts with multiple images received lower scores (P<.001) but a greater number of comments (P<.001) compared with posts with a single image.

Discussion

Principal Findings

Our study provides an in-depth examination of user dynamics within the subreddit r/medical_advice, illuminating the intricacies of online health information–seeking behaviors. Our findings align with established medical literature on online medical information seeking. Online health forums have been shown to frequently serve as primary sources for addressing nonurgent and less severe medical concerns [8]. The high volume of posts on noncritical health issues suggests a common use of these platforms. It is reasonable to think that users are seeking preliminary advice, or perhaps just reassurance, before consulting a health care professional due to the ease of access to online medical information. Of note, the high level of engagement with pregnancy-related posts is a trend mirroring other online health communities [9], highlighting a consistent public interest in reproductive health.

In addition, our study explored the engagement dynamics of posts containing visual media, an area of study that is lacking in current medical literature. Our results show that posts featuring images or videos, especially concerning dermatological issues such as skin rashes or moles, have attracted higher levels of engagement. This observation not only underscores the effectiveness of visual aids in communicating complex medical information but also hints at a growing user preference for multimedia content [10]. With the rise of telemedicine and digital health communication in the post–COVID-19 era, the importance of visual aids in enhancing both diagnosis and patient understanding cannot be overstated.

Another intriguing aspect of our study is the significant contribution of nonverified medical professionals in providing advice. Our results show that r/medical_advice relies heavily on contributions from laypersons. This may be due to the lack of a robust verification process on the platform as it relies on the user to self-identify. This trend reflects a broader shift in the digital health information landscape, where community-based knowledge exchange is becoming increasingly predominant over traditional expert-driven models. While this democratization of health information has its advantages, it also inevitably raises concerns about the accuracy and reliability of the advice shared—challenges that have been extensively documented [11].

A key limitation of this study is that 41% of posts lacked user flairs, which leaves a significant portion of users' backgrounds unclear. We acknowledge this as a potential source of bias and recommend future investigations using natural language processing or other linguistic analysis methods to characterize these flairless users, which could enhance our understanding of their information-seeking patterns. In addition, by focusing solely on a single subreddit, we acknowledge that our findings

XSL•FO
RenderX

may not fully represent online health-seeking behaviors across various platforms and communities. The unique characteristics of r/medical_advice—including its user demographics, content moderation practices, and engagement patterns—may not perfectly mirror those of other online health forums. Furthermore, the study's reliance on user-generated categorizations for post flairs and the self-identification of medical professionals introduces potential biases and inaccuracies, which could affect our interpretation of the data [12].

In terms of future directions, numerous opportunities for further research present themselves. Comparative studies across various social media platforms could examine unique trends and user behaviors, offering a more comprehensive picture of online health-seeking patterns. Further investigation into the truthfulness and impact of advice provided by online users remains a critical area of exploration [13]. In addition, understanding the motivations behind patients turning to social media for medical advice, and the consequences of acting on potentially incorrect information, is important to assess these platforms' impact on public health and health care costs.

Conclusion

Our investigation into r/medical_advice uncovers a complex and evolving landscape where online platforms serve as significant avenues for medical inquiry and information exchange. This study highlights the role of both professional and nonprofessional users in shaping these interactions and emphasizes the value they bring. While these platforms may offer invaluable opportunities for information sharing and support, the variable quality and reliability of the advice provided require careful consideration from the professional medical community. There is a clear need for increased participation from verified medical professionals and the implementation of effective moderation policies to ensure that online health forums function as reliable and supportive communities for individuals seeking medical guidance. Such measures are vital to mitigate the risks of misinformation and foster a safer, more informed online health ecosystem.

Abstract

Background: High blood pressure (≥140/90 mm Hg) is the most prominent mortality risk factor worldwide. Home blood pressure measurement (HBPM) is recommended for blood pressure (BP) management. HBPM is most effective to improve BP management when delivered with patient education. It is unknown whether web-based resources are appropriate for patient education for HBPM. Patient education should provide accurate, evidence-based information, communicate at an eighth grade reading level, and involve end users in development to meet the needs of adults of all health literacy levels. Using these criteria, this study aimed to determine the appropriateness of web-based HBPM resources.

Objective: This study aimed to determine whether web-based resources are appropriate for HBPM education based on three research questions: (1) Do web-based resources provide evidence-based information that aligns with guideline recommendations? (2) Do they communicate at an appropriate reading level? (3) Do they involve end users in their development?

Methods: An environmental scan of web-based resources for HBPM was conducted on Google (October 2022) using search terms developed with consumers (n=6). Resources were included if they were identified on the first page of the search findings, not paywalled, and in English. Resource appropriateness was appraised based on three criteria: (1) alignment of resource content to 23 recommendations for HBPM from 6 international guidelines, (2) being at an appropriate grade reading level as determined by a health literacy assessment software, and (3) having evidence of end user involvement in resource development.

Results: None of the identified resources (n=24) aligned with all 23 of the guideline recommendations. All resources aligned with the recommendation to measure BP when seated, while few aligned with the recommendation to use a validated BP device (n=9, 38%). All resources exceeded the recommended eighth grade reading level (mean 11.8, range 8.8-17.0) and none reported evidence of patient end user involvement in development.

Conclusions: None of the web-based resources met the criteria for appropriate education to support adults to measure BP at home. Resources should be developed with end users using health literacy tools and multimodal communication methods to ensure they are appropriate to meet the needs of patients.

KEYWORDS

readability; online resources; blood pressure guidelines; end user; home blood pressure measurement; patient education; educational resource; self-education; hypertension

Introduction

High blood pressure (BP; hypertension: BP≥140/90 mm Hg) is the leading risk factor for death worldwide [1,2]. High BP can be controlled (<140/90 mm Hg) via medication and lifestyle changes to reduce the risk of heart attack and stroke [3]. Home BP measurement (HBPM) is widely recommended to inform hypertension diagnosis and to monitor the control and ongoing management of BP [4-7]. HBPM provides accurate, standardized BP readings, which have greater prognostic value for cardiovascular disease when performed according to guideline recommendations [8]. Adults who measure BP at home are more engaged in BP management and achieve greater BP control [9]. Further, several studies, including a recent meta-analysis, highlight that HBPM is only effective for improving BP management when accompanied by appropriate patient education on how to measure HBPM accurately and act on BP readings [7,10,11]. However, there is a lack of guidance and standardized resources to provide effective education for HBPM in clinical settings [11,12].

In the absence of effective in-clinic education and with the increased use of telehealth, web-based resources are commonly used by adults who seek health-related information for self-education [13]. In addition, recent work in Australia has shown that >35% of adults would prefer to access information about high BP on the web [14]. With this evolution of health care and patient education delivery, government bodies have emphasized the need for web-based resources to provide health information that is evidence-based and understandable [15]. More specifically, several systematic reviews on eHealth, mobile health, and other digital strategies to improve BP management also suggest a growing need to ensure that appropriate education is available on the web to support adults to undertake HBPM [16-18].

Web-based educational resources that are appropriate to support adults to perform HBPM should deliver evidence-based information in a manner that meets the health literacy and learning needs of most adults. To do this, information should be presented at an eighth grade reading level, with the use of visual aids such as graphics to support understandability [19,20]. The use of co-design methods involving target end users during resource development is an effective method to ensure that resources meet the needs of end users for effective patient education [21-24]. However, previous research has shown that web-based educational resources for cardiovascular disease risk management do not provide appropriate information or meet the usability or readability needs of adults [18,25-29], and co-design involving end users (such as community members and medical professionals) is an underused method during resource development [24]. Due to the importance of patient education for HBPM to achieve improved BP control and patient self-efficacy in BP management, patient education resources for HBPM should be appropriate for use by adults who self-monitor BP.

The aim of this study was to determine whether web-based resources are appropriate for HBPM patient education based on three research questions: (1) Do web-based resources provide evidence-based information that aligns with guideline recommendations? (2) Do they communicate at an appropriate reading level? (3) Do they involve end users in their development?

Methods

Study Design

An environmental scan of web-based resources on HBPM was conducted through a Google search designed to emulate the approach taken by adults with lived experience of HBPM when seeking web-based material about HBPM [27]. The resources were characterized according to basic identifying features such as publishing organization and year. Resources were assessed for alignment with 23 recommendations common across 6 international guidelines that encompass HBPM activities including acquiring the BP measurement device, scheduling and preparing for HBPM, selecting and fitting the cuff, BP measurement conditions, and recording and reporting BP readings (Textbox 1 and Multimedia Appendix 1) [6,30-34]. The grade reading level of the content of the resources was determined using the health literacy assessment software Sydney Health Literacy Lab Editor (SHeLL Editor) [19,35,36]. The recommended reading level for maximum comprehension for adults is eighth grade or below [19]. Involvement of community member and/or medical professional end users in resource development was assessed according to whether this was reported within each resource. Data extraction and resource appraisal were undertaken by 2 independent researchers (EC and SC) using a coding framework hosted on the secure web-based platform REDCap (Research Electronic Data Capture; Vanderbilt University) [37].

Textbox 1. Twenty-three key guideline recommendations for home blood pressure measurement.

Acquiring the blood pressure (BP) measurement device:

- Use a validated BP measurement device for home BP measurement (HBPM).
- Finger cuff BP measurement devices should not be used for HBPM.

Scheduling HBPM:

- On a day that HBPM is being conducted, BP should be measured in the morning and the evening.

Preparing for HBPM:

- Do not measure BP if uncomfortable, stressed, or in pain.
- Measure BP before medication.
- Measure BP before eating or 30 minutes or 2 hours after eating.
- Measure BP after emptying the bladder.
- Measure BP before exercise or 30 minutes after exercise.
- Measure BP before consuming caffeine or after 30 minutes or 1 hour of consuming caffeine.
- Measure BP before smoking or 30 minutes or 1 hour after smoking.
- Have 5 minutes, or at least 5 minutes, of seated rest before measuring BP.

Selecting and fitting the cuff:

- Use an appropriately sized arm cuff for HBPM.
- The arm cuff should fit the arm within the accepted range indicated on the cuff.
- Fit the upper arm BP cuff to a bare arm.

Measurement conditions:

- Measure BP in a room at a comfortable temperature.
- Measure BP with the arm fitted with the cuff supported or supported at the heart level.
- Measure BP in a seated position.
- Measure BP with both feet flat on the floor.
- Measure BP with legs uncrossed.
- Measure BP with back supported.
- Take 2 readings 1 minute apart at each HBPM sitting.

Recording and reporting BP:

- Average the BP readings taken over a 7-day period, discarding the first day.
- Take a copy of home BP readings to a doctor.

Search Strategy

The search engine Google Australia was used to identify web-based resources addressing HBPM. Seven search terms were developed with trained research consumer advisors who have lived experience of BP management and using Google Trends (Multimedia Appendix 2). Consumer advisors (n=6) identified the search engine and the top 5 search terms they would use to find information about HBPM on the web. Google Trends was used to identify the search queries related to the term "home blood pressure measurement," which had the highest probability of use worldwide on Google from January 1, 2012, to October 7, 2022. Search terms suggested by consumer advisors, which also had high probability of use on Google according to Google Trends and were relevant to HBPM were used. Search terms included the following: "How to take your blood pressure," "How to check blood pressure at home," "How to take blood pressure at home," "Home blood pressure monitoring," "How to measure blood pressure at home," "How to monitor blood pressure at home," and "Home blood pressure measurement."

Data Extraction From Web-Based Resources

Data extraction was undertaken independently by 2 investigators (EC and SC) on October 17, 2022 (duplicate search). To avoid potential bias attached to the reviewers' Google history, each reviewer conducted the search using default Google search settings within the incognito browser of Google Chrome and cleared the cache before each search. The results obtained with each search term, which were present on the first page of the

XSL•FO
RenderX

search findings on Google, were exported, excluding advertisements. After completing all searches, the resources extracted by each reviewer across all search terms were combined, and duplicate resources were removed (ie, resources identified across >1 search term).

Inclusion Criteria for Web-Based Resources

HBPM resources were included if they met the following inclusion criteria: (1) they were free to access by the public (eg, no paywalls), (2) they were available in English, and (3) they contained content relevant to HBPM (eg, resource mentions "home blood pressure measurement" or "self-measured blood pressure"; Multimedia Appendix 3). The resources extracted from Google were independently analyzed against inclusion criteria by EC and SC, and discrepancies were resolved by third and fourth independent reviewers based on the same criteria (NC and DP). All resources that met the inclusion criteria were included for analysis. Resources were not excluded due to criteria regarding publication date, publication location, or resource format (ie, video, graphic, or blog).

Appraisal of Web-Based Resources

A coding framework hosted on REDCap was used by EC and SC to independently and systematically appraise resources according to three criteria: (1) alignment of resource information with HBPM guideline recommendations, (2) grade reading level of the content of the resources, and (3) end user involvement in resource development. The REDCap appraisal framework captured resource characteristics (type of publishing organization, authorship, year of publication or last review, and location of publication and languages), communication methods used (categorized as written text, visual, video, or audio), the alignment of resource content against HBPM recommendations, and the grade reading level of the content of the resources (Multimedia Appendix 3). Independent reviewers were trained on how to undertake the search, extract data, and appraise resources. During training, the appraisal data of a subset of resources (n=3) were compared to ensure that the correct process was undertaken by both independent reviewers. All data were captured in a framework housed on REDCap. All content (including audio, text, video, and graphical content) included within each HBPM resource was appraised according to 3 main criteria detailed below. Any discrepancies in appraisal were resolved in adjudication sessions where blinded discrepancies were presented to adjudicators (NC and DP) and resolved via discussion until consensus was reached.

Alignment of Resource Information With HBPM Guideline Recommendations

Twenty-three recommendations that encompass activities for HBPM from 6 international guidelines were used to determine the alignment of resource content to the guidelines (Textbox 1) [6,30-34]. Resource content was marked against each recommendation and categorized as "aligned with" if the resource correctly stated the recommendation, "incorrectly stated" if the resource incorrectly or incompletely stated the recommendation, or "not mentioned" if the resource did not include the recommendation (Multimedia Appendix 3). Where resources "incorrectly stated" a guideline recommendation, the incorrect information provided by the resource was recorded on REDCap (Multimedia Appendix 4).

Grade Reading Level of Resource Text

The grade reading level of each resource was calculated using the SHeLL Editor, which is a health literacy assessment tool that calculates the school grade reading score of text according to the Simple Measure of Gobbledygook, and reports other measures such as complex language, uncommon English words, and the use of passive voice [19,35,36]. All text presented within each resource (including written text, image captions, and audio and video transcripts when available) was entered into the SHeLL Editor and the grade reading level, and associated measures were recorded in the REDCap framework (Multimedia Appendix 3).

End User Involvement in Resource Development

End user involvement in resource development was recorded in the REDCap framework as stated within the resource. End users were defined as adults who seek information to measure BP at home (eg, patient, health consumer, service user, carer, or community advisor) or medical professionals due to their role in delivering education for HBPM to adults or directing adults to educational resources for HBPM [38,39].

Data Analysis

Data were analyzed using Stata (version 17; StataCorp). Resources were assigned an identifying number for analysis and the presentation of results (Multimedia Appendix 5). Categorical data are presented as n (%) values.

Results

Resource Characteristics

Twenty-four resources were included in the study (Multimedia Appendices 5 and 6). Not-for-profit organizations (such as the National Heart Foundation) were the most common type of publishing organization (n=6, 25%) followed by websites (such as Healthline), academic journals, and scientific societies (Table 1). Most resources were communicated via a combination of written text, visual (eg, images), and audio and video communication methods (n=17, 71%), and the remaining resources were communicated by written text only (n=7, 29%; Table 1). Most resources were published in Australia (n=10, 42%) or North America (n=9, 38%), and only 3 (13%) were available in languages other than English.

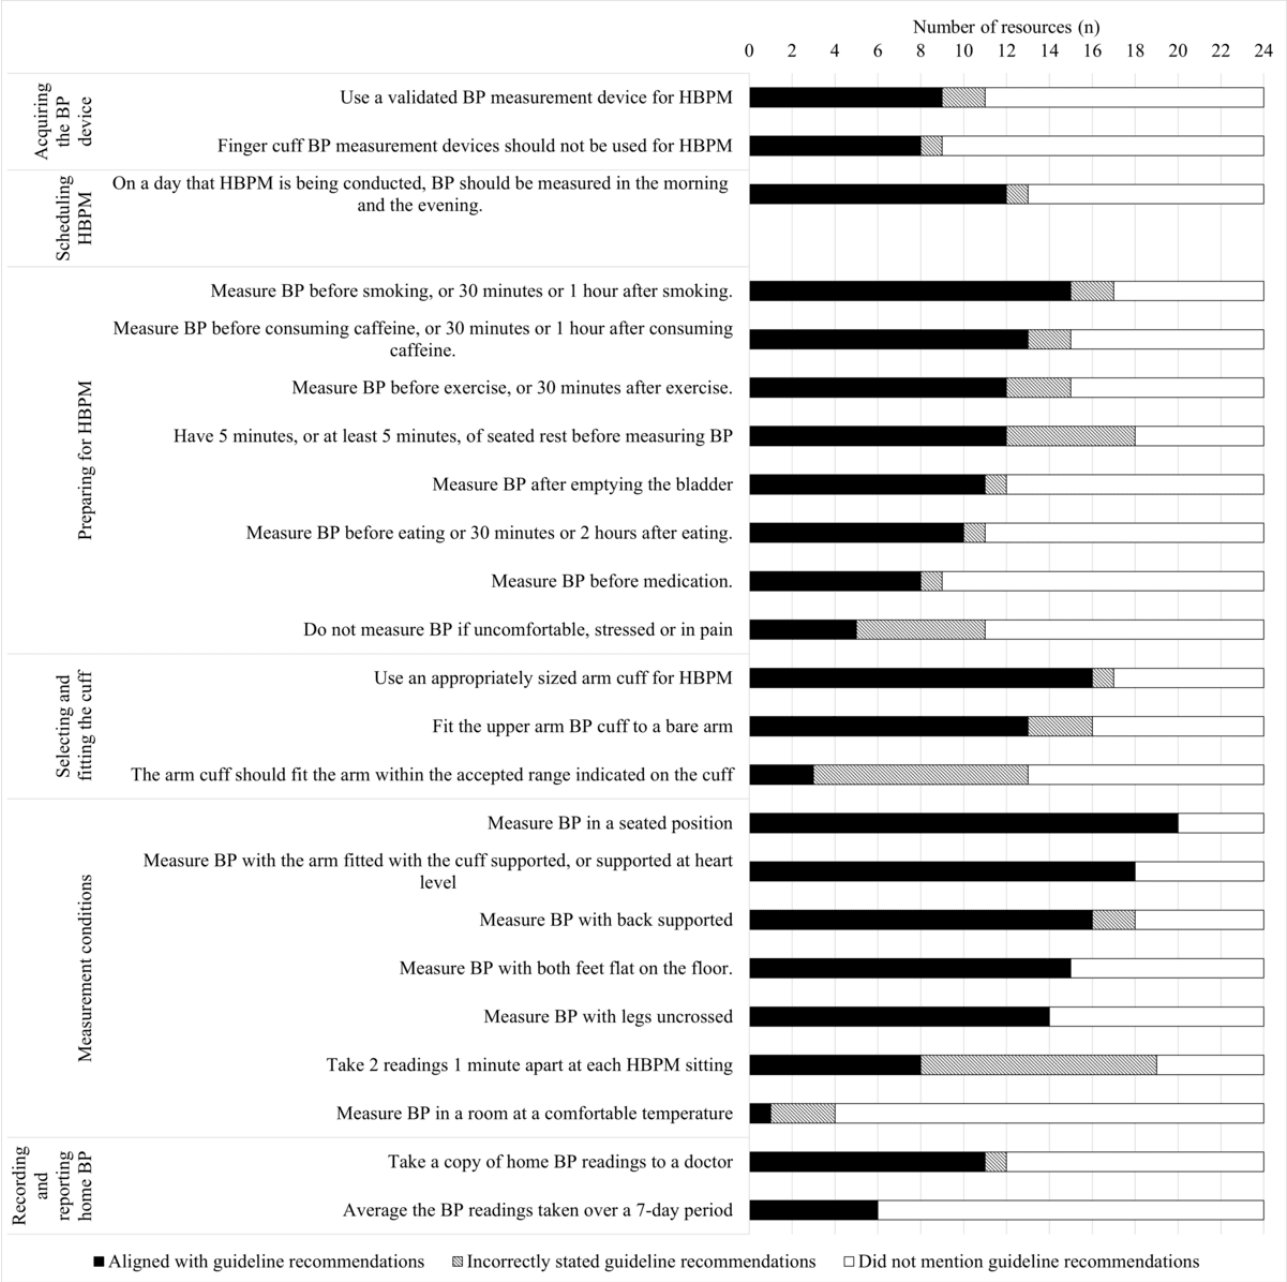
Resource Alignment With HBPM Guideline Recommendations

As shown in Figure 1, none of the resources aligned with all 23 guideline recommendations for HBPM. Almost all (n=22, 92%) of the resources incorrectly stated at least one guideline recommendation. Two (8%) resources did not align with any of the 23 guideline recommendations for HBPM. The alignment of resources with each guideline recommendation is shown in Figure 2, indicating whether the recommendation was “aligned with,” “incorrectly stated,” and “not mentioned” in each resource. Time- or frequency-bound recommendations were often incorrect within resources. For example, to rest for 5 minutes before measuring BP was incorrectly stated in 25% (n=6) of resources and to take 2 BP readings 1 minute apart at each sitting was incorrect in 46% (n=11) of resources (Figure 2).

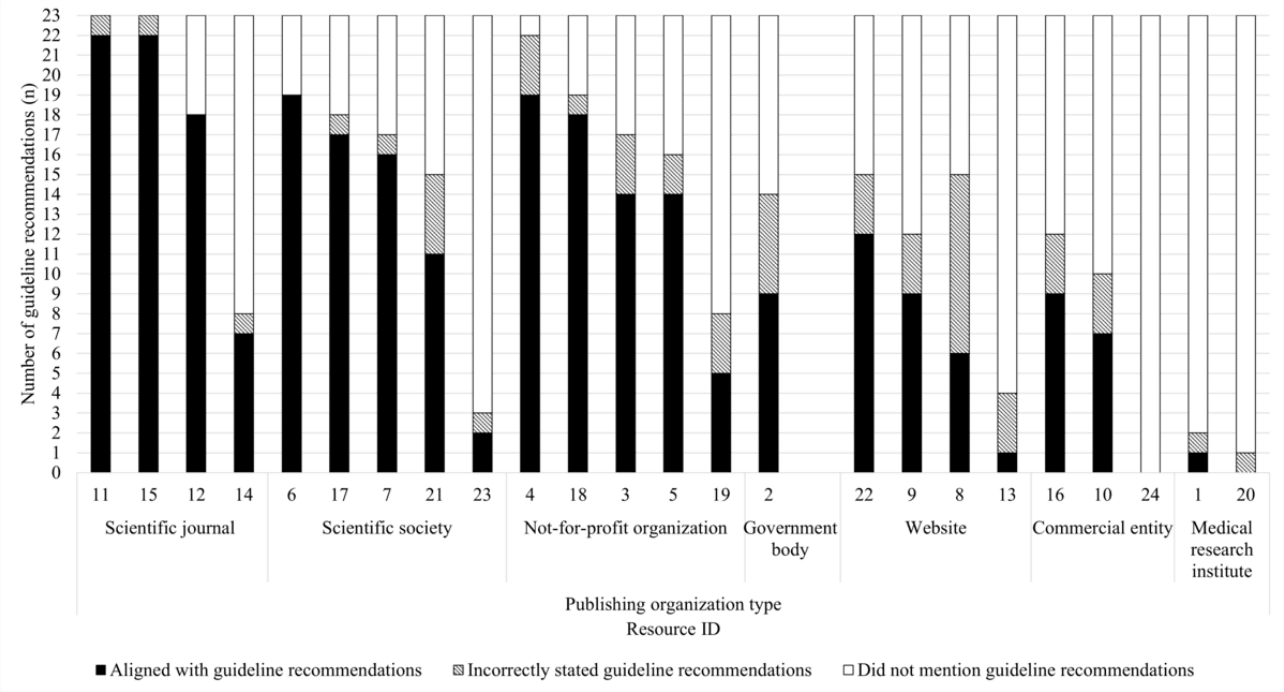
XSL•FO
RenderX

Figure 1. Alignment of each resource to 23 guideline recommendations for home blood pressure measurement. Resource content either "aligned with" the HBPM guideline recommendations (black bars), "incorrectly stated" the guideline recommendations (patterned bars), or "did not mention" the guideline recommendations (white bars). The y-axis indicates each of the 23 guideline recommendations, and the x-axis indicates the number of resources (n=24 resources).



Resources incorrectly stated guideline recommendations because their content was not specific enough to capture the meaning of the guideline recommendation, provided contradictory advice, or stated an alternate rest period, number of measurements, frequency, duration, or other numeric parameters to the guideline recommendations (Multimedia Appendix 4). For example, rather than stating the recommendation to “have five minutes [or at least five minutes] of seated rest before measuring BP,” resources that incorrectly stated this recommendation said to “rest for 15 minutes” (resource ID 10) or “rest quietly and wait about one to two minutes before taking another measurement” (resource ID 19). In addition, rather than stating the recommendation to “take two readings one minute apart at each HBPM sitting,” a resource that incorrectly stated this recommendation said “if you get a reading that is slightly or moderately higher than normal, take your blood pressure a few more times” (resource ID 6).

Resource alignment to guideline recommendations according to the publishing organization is outlined in Figure 3. Resources published by scientific journals, scientific societies, and not-for-profit organizations aligned with a higher number of HBPM guideline recommendations (14 resources; median 16.5, range 2-22 recommendations) than resources published by websites, commercial entities, and medical research institutes (9 resources; median 6.5, range 0-12 recommendations; Figure 3).



XSL•FO
RenderX

Figure 2. Alignment of all resources to each of the 23 guideline recommendations for key home blood pressure measurement (HBPM) activities. Resource content either "aligned with" the HBPM guideline recommendations (black bars), "incorrectly stated" the guideline recommendations (patterned bars), or "did not mention" the guideline recommendations (white bars). The x-axis indicates the number of HBPM resources. BP: blood pressure.

XSL•FO
RenderX

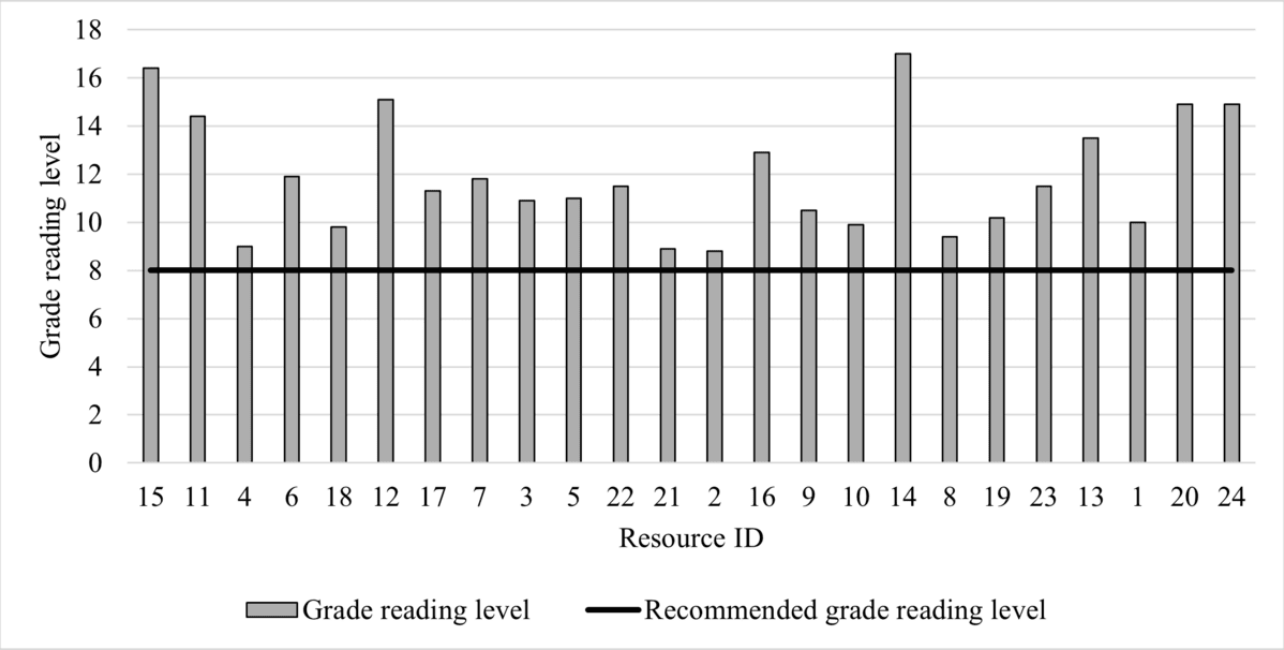


Figure 3. Resource alignment to home blood pressure measurement (HBPM) guideline recommendations according to the type of publishing organization. Resource alignment was determined by appraising resource content against 23 guideline recommendations of core HBPM activities. Resource content either "aligned with" the HBPM guideline recommendations (black bars), "incorrectly stated" the guideline recommendations (patterned bars), or "did not mention" the guideline recommendations (white bars).

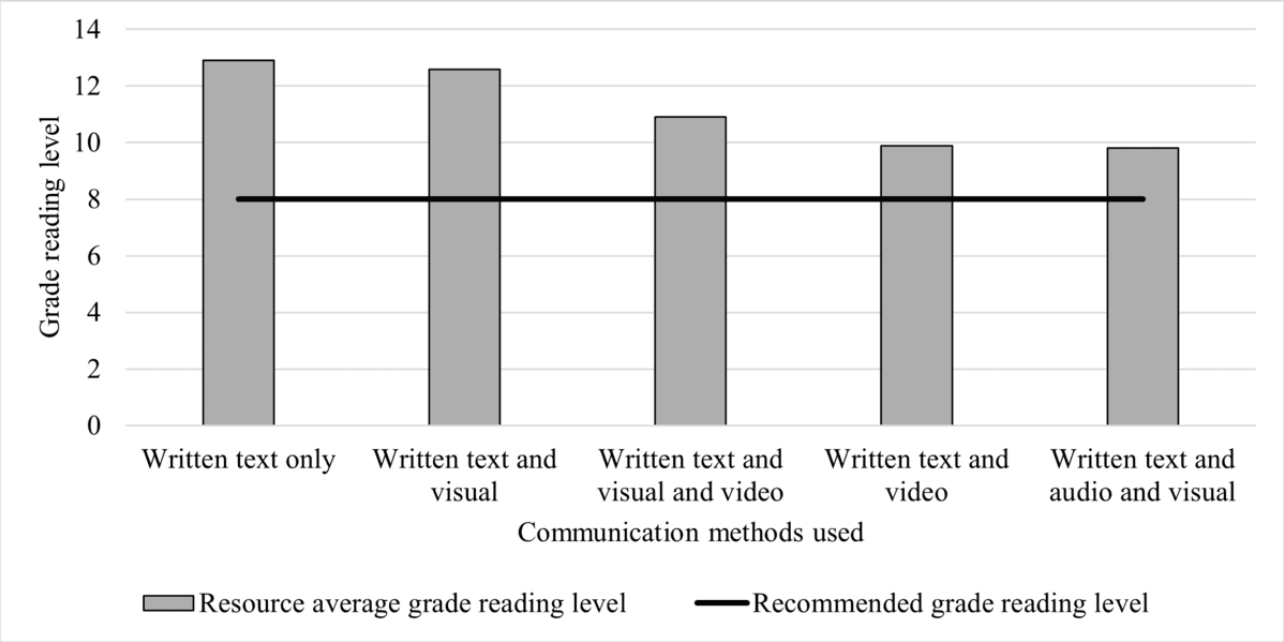
Grade Reading Level of Resource Text

All resources exceeded the recommended eighth grade reading level (grade reading level: mean 11.8, range: 8.8-17.0; Figure 4). The grade reading level of resources did not differ according to the level of alignment with HBPM guideline recommendations or communication methods used (Figures 4 and 5). Resources presented through written text only (n=7) had the highest average grade reading level (grade reading level: mean 12.9, range 10.5-16.4; Figure 5). Resources published by scientific journals had the highest average grade reading level (n=4; grade reading level: mean 16.5, range 11.9-17), compared to government bodies (n=1; grade reading level: mean 8.8) and not-for-profit organizations (n=5; grade reading level: mean 10.2, range 9-10.9; Figure 6), which had the lowest average grade reading levels. Multimedia Appendix 7 shows the characteristics of the resource text that contributed to the grade reading level score.

Figure 4. Grade reading level of web-based home blood pressure measurement (HBPM) resources. Resource grade reading level (y-axis) is presented in the order of resources from the highest (left) to the lowest alignment (right) with HBPM guideline recommendations. The grade reading level (y-axis) of resource content was calculated by inputting all resource content into the Sydney Health Literacy Lab Editor.

XSL•FO
RenderX

Figure 5. Resource grade reading level according to the communication method. The average grade reading level (y-axis) of resources according to communication methods used in the resource (x-axis). The grade reading level (y-axis) of resource content was calculated by inputting all resource content into the Sydney Health Literacy Lab Editor.



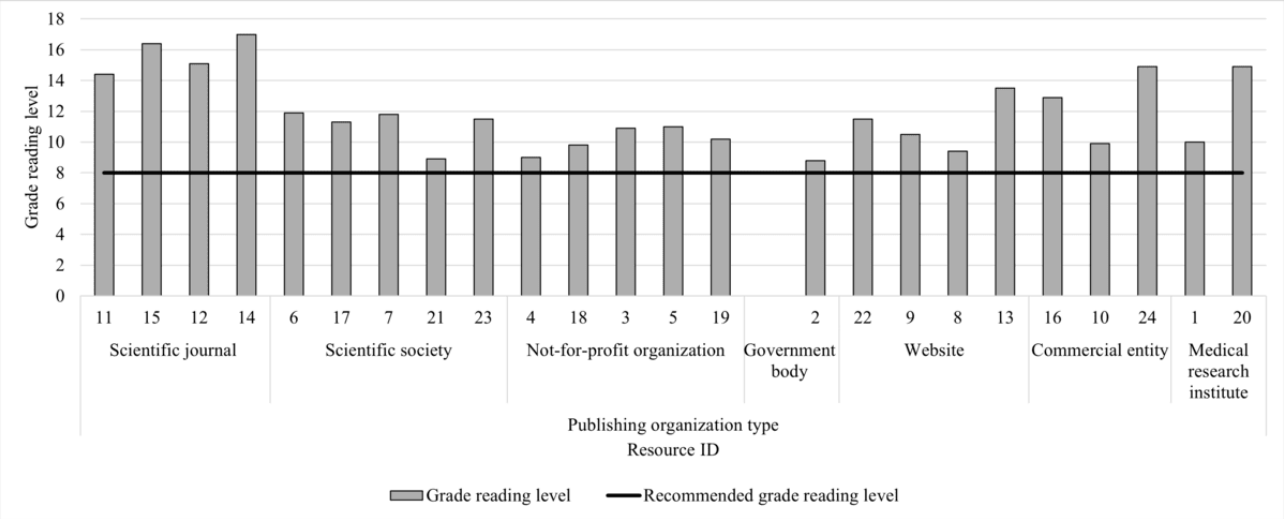


Figure 6. Resource grade reading level according to the type of publishing organization. Grade reading level was calculated by inputting all resource content into the Sydney Health Literacy Lab Editor.

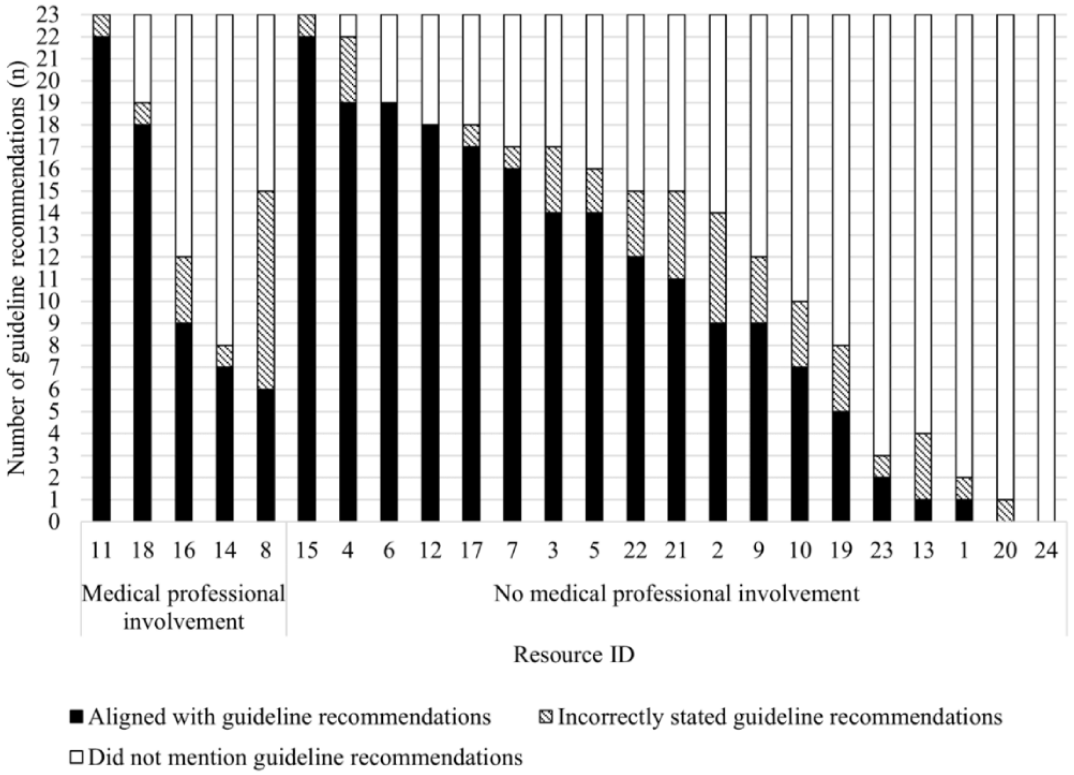
End User Involvement in Resource Development

None of the resources reported involving adults (such as patients, health consumers, or carers) during resource development. Medical professional involvement was reported in 5 (21%) resources. Resources with and those without medical professional involvement during development had similar alignment with HBPM guideline recommendations and grade reading levels (Figures 7 and 8).

XSL•FO
RenderX

Figure 7. Resource alignment to guideline home blood pressure measurement (HBPM) recommendations according to medical professional involvement during resource development. Resource alignment was determined by appraising resource content against 23 guideline recommendations of core HBPM activities. Resource content either "aligned with" the HBPM guideline recommendations (black bars), "incorrectly stated" the guideline recommendations (patterned bars), or "did not mention" the guideline recommendations (white bars).



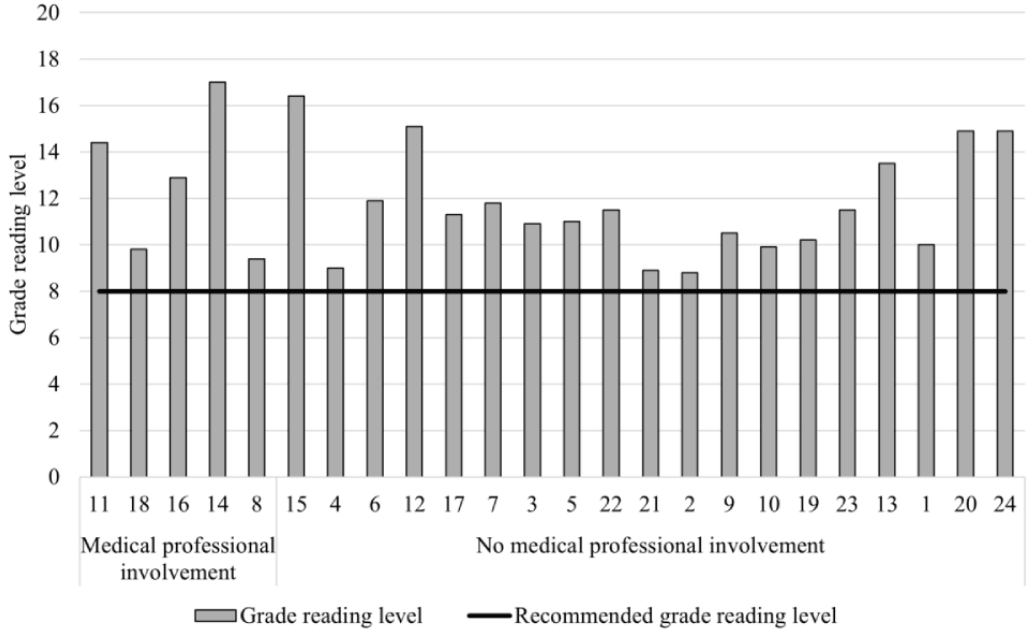


Figure 8. Resource grade reading level according to medical professional involvement during resource development. Grade reading level was calculated by inputting all resource content into the Sydney Health Literacy Lab Editor. Resources are presented in order of the highest (left) to the lowest alignment (right) to home blood pressure measurement guideline recommendations.

Discussion

Principal Findings

This study has demonstrated that web-based resources may not be appropriate to fully support adults to undertake high-quality HBPM because none of them provided sufficient guideline information or communicated at an appropriate reading level. Using methodology that emulated the search strategy of adults with lived experience of HBPM to identify web-based resources, we identified that none of the resources correctly stated all key guideline recommendations for HBPM, and most resources included information that was incorrect according to guideline

XSL•FO
RenderX

recommendations due to incorrectly stating time- and frequency-bound recommendations. The findings of this study highlight the need to design educational materials for key BP management behaviors such as HBPM, which are appropriate for adults who self-monitor BP.

Calls to action on hypertension in the United States and Australia highlight the importance of empowering patients who perform HBPM to improve and monitor BP control [40,41]. At a global level, the World Heart Federation Hypertension Roadmap highlighted that appropriate patient education is an important strategy to improve BP control [20]. Existing research supports this by illustrating that patient education delivered with HBPM improves BP control outcomes [10] and adherence to recommendations for HBPM [11,42]. However, the results of this study suggest that web-based resources may not be appropriate to educate adults about HBPM as the identified resources did not provide guideline aligning information required to support HBPM in a manner that met adult reading needs.

This study found that time- and frequency-based HBPM recommendations, such as the number of BP measurements to take per sitting and the associated rest periods, were incorrectly stated within the most resources, while the recommendation to measure BP when seated was accurately communicated in the most resources. Interestingly, a recent study on BP guideline recommendations followed by adults who measure BP at home found that time-bound recommendations were adhered to by the lowest number of adults, while the recommendation to measure BP when seated was performed by the highest number of adults. Additionally, adults who reported to have previously sought information to support HBPM did so via web-based sources; however, these adults did not perform higher-quality HBPM than those who had not used web-based information to support HBPM [43]. Altogether, these findings highlight that current educational resources are not appropriate to support adults to measure BP at home as recommended by guidelines and illustrate a possible synergy between the inaccurate information delivered within web-based HBPM resources and the practice of adults when measuring BP at home. This emphasizes the need for web-based HBPM resources to accurately and clearly deliver guideline recommendations to enable proper HBPM practice among adults, which is an important behavior for BP management.

This study found that resources published in scientific journals, scientific societies, and not-for-profit organizations stated more guideline recommendations correctly than resources published by websites, commercial entities, and medical research institutes. This suggests that some organizations and resource developers may have low awareness of or access to guideline recommendations for HBPM and may not recognize the importance of standardized BP measurement practices for achieving and maintaining BP control. International BP guidelines should consider the importance of using consistent, unambiguous, and plain language for HBPM recommendations to support the accurate translation of recommendations into educational resources for HBPM. To ensure that guideline information is disseminated to the general public, guideline developers should share guidelines with organizations that publish health information on the web and partner with peak organizations to enable resource developers from outside of the scientific and clinical community to create guideline-informed, evidence-based resources.

Apart from correctly delivering evidence-based guideline information, HBPM resources must deliver information in a format accessible for adults to achieve effective education. Previous evidence has shown that web-based health information is not appropriate to inform patient decisions surrounding cardiovascular disease because the reading level is too high and the information is not adapted to meet the learning needs of adult patients [17,26,27,44]. This is consistent with the findings of our study where all resources were at a reading level that was too high (≥8 grade) for adult comprehension and over a quarter (n=7, 29%) of resources only presented information via written text only.

Strategies to deliver patient education that meet the literacy levels of adult patients should be implemented to ensure that educational resources can support adults to perform key cardiovascular disease risk management behaviors such as HBPM. As highlighted by the World Heart Federation Hypertension Roadmap, the delivery of education via graphical means is a more appropriate communication method to meet the needs of those with lower health literacy levels [20]. This is supported by the findings of this study, where web-based resources with multimodal communication methods achieved a lower average grade reading level than those that communicated via written text alone. Supporting audiovisuals, such as graphs, diagrams, images, videos, and the read-aloud function should be used to aid understandability, comprehensibility, and actionability of web-based health information. Additionally, the use of readability and grammar editing tools when developing resources may help to ensure that resource information is presented at a grade reading level that is appropriate to all adults, and resources such as the Agency for Healthcare Research and Quality's Health Literacy Universal Precautions Toolkit may provide actionable methods to maximize the understandability of patient education strategies [45]. Finally, artificial intelligence (AI) could be used to tailor web-based information to meet patient literacy needs, selectively deliver information most relevant to the unique information needs of patients, and support chat box functions enabling adults to ask clarifying questions [46]. However, although AI-generated content is accurate and retains key meaning, caution should be exercised to ensure that information used by AI generators is sourced from guidelines.

Direct end user involvement in resource development is an increasingly well-recognized strategy to ensure that health products and services, including health information, meet end user needs to deliver quality care and education [21-24]. However, end user involvement is not commonplace in resource development [24], which is consistent with the findings of our study. Although some resources of this study involved medical professionals in their development, this did not improve the resource grade reading level or the number of correctly stated guideline recommendations. While medical professionals play a central role in patient education, they may not be aware or have sufficient resources to meet the health literacy needs of

XSL•FO
RenderX

all patients [47-49]. Additionally, some medical professionals have general distrust in BP guidelines [50] and do not use current guidelines recommendations for HBPM in clinical practice, such as the recommendation to use different cutoffs for a hypertension diagnosis using in-clinic versus at-home BP readings [12,51]. This further highlights the need for adults with lived experience of BP management to be involved in resource development to identify unfamiliar medical jargon, recommend culturally and linguistically sensitive adaptations, and advise on the appropriate use of images. For existing resources, such as those identified in this study, adults could be involved in appraising these resources to identify how they could better meet the needs of adults seeking information on HBPM. Implementing the strategies suggested would ensure that information provided by web-based resources is suitable for use by all end users to support high-quality HBPM among adults.

Strengths and Limitations

A strength of this study was the involvement of consumer advisors in the development of the search strategy to emulate the experience of adults seeking information for HBPM. In addition, a rigorous framework analysis approach was used by 2 independent researchers for resource identification and appraisal. This study was strengthened by the guideline-informed appraisal process; however, guideline recommendations included in this analysis were not exhaustive of all recommendations for HBPM due to inconsistency in recommendations across guidelines. The incognito mode was used to eliminate the impact of cookies and search history unique to the reviewer. However, as a result of using default Google search engine settings and including only the first page of search results, some web-based HBPM resources would have been missed. The location at which this study was conducted has likely impacted the search results, as 42% of included resources were from Australia. This suggests that the resources that an adult seeking HBPM information is exposed to depends on the location from which the search is conducted. This method should be replicated in other locations to assess resources that may not have been identified in this study. The scope of this study was narrow, with highly specific appraisal criteria used to evaluate resources. Other important considerations of web-based resources such as ease of access and usability should be included in future studies for a more complete understanding of resource appropriateness to support HBPM. Further, given the proliferation in use of AI, mobile health, and eHealth for health interventions and patient education, HBPM resources found on these information sources should also be appraised for appropriateness.

Conclusion

This study found that the web-based resources identified herein are not appropriate to fully support adults to measure their BP at home according to HBPM guideline recommendations. None of the resources identified provided sufficient guideline information to support adults to perform high-quality HBPM, were presented at an appropriate reading level, or involved end users in their design. Resources that deliver health information should use strategies such as the use of multimodal communication methods, literacy editor tools, and co-design methods with adult end users to ensure that the information delivered is appropriate to support adults. Due to the recognized importance of effective education in achieving standardized HBPM and improving BP control, creating appropriate educational resources for key BP management behaviors such as HBPM should be considered a priority.

Acknowledgments

We sincerely thank John Stevens, Carol Batt, Michael Whittle, Josephine Castillo, Lesley Hall, and Heather Thurstans for their contributions to this work as consumer advisors with lived experience. NC was supported by an Australian Heart Foundation Postdoctoral Research Fellowship for the duration of this work. CB was supported by a Heart Foundation Future Leader Fellowship. DP was supported by a National Health and Medical Research Council Investigator Grant (GNT2018077) and was an Honorary Future Leader Fellow of the Heart Foundation of Australia (106618).

Data Availability

The data that support the findings of this study are available from the corresponding author (NC) upon reasonable request. NC had full access to all data in the study and takes responsibility for its integrity and the data analysis.

Conflicts of Interest

CB is a director of Health Literacy Solutions, a company set up to fund the future development of the SHeLL Editor.

Abstract

Background: Social media has been extensively used by the public to seek information and share views on health issues. Recently, the proper and off-label use of semaglutide drugs for weight loss has attracted huge media attention and led to temporary supply shortages.

Objective: The aim of this study was to perform a content analysis on English YouTube (Google) videos related to semaglutide.

Methods: YouTube was searched with the words semaglutide, Ozempic, Wegovy, and Rybelsus. The first 30 full-length videos (videos without a time limit) and 30 shorts (videos that are no longer than 1 minute) resulting from each search word were recorded. After discounting duplicates resulting from multiple searches, a total of 96 full-length videos and 93 shorts were analyzed. Video content was evaluated by 3 tools, that is, a custom checklist, a Global Quality Score (GQS), and Modified DISCERN. Readability and sentiment of the transcripts were also assessed.

Results: There was no significant difference in the mean number of views between full-length videos and shorts (mean 288,563.1, SD 513,598.3 vs mean 188,465.2, SD 780,376.2, P=.30). The former had better content quality in terms of GQS, Modified DISCERN, and the number of mentioned points from the custom checklist (all P<.001). The transcript readability of both types of videos was at a fairly easy level and mainly had a neutral tone. Full-length videos from health sources had a higher content quality in terms of GQS and Modified DISCERN (both P<.001) than their counterparts.

Conclusions: The analyzed videos lacked coverage of several important aspects, including the lack of long-term data, the persistence of side effects due to the long half-life of semaglutide, and the risk of counterfeit drugs. It is crucial for the public to be aware that videos cannot replace consultations with physicians.

YouTube; semaglutide; social media; Ozempic; Wegovy; Rybelsus; safety; knowledge exchange; side effects; online information; online; videos; health issues; drugs; weight loss; assessment; long-term data; consultation

Introduction

Public health information has traditionally been disseminated through printed media. However, with the rise of online social media platforms [1], the internet has become increasingly influential in spreading information and misinformation, notably during the COVID-19 pandemic [2-5]. Safety concerns in health care are frequently discussed on social media platforms such as YouTube (Google) [2,6].

Currently, obesity and being overweight are urgent health issues that reduce quality of life and increase the risk of cardiovascular diseases, type 2 diabetes mellitus, cancers, and reproductive system disorders, among others [7]. While lifestyle changes are essential for managing obesity, many people struggle with adherence [8]. Consequently, medical organizations are developing clinical guidelines for the long-term use of pharmacological therapy for obesity in adults. For instance, the American Gastroenterological Association recommends the use of pharmacological agents (strong recommendation, moderate certainty evidence) for adults with obesity or overweight who have insufficient results from lifestyle changes [8].

Unfortunately, some patients take their own antiobesity medication based on social media information, which can be dangerous without professional guidance. In particular, many people have watched YouTube videos on weight loss. It was found that the 98 most viewed weight loss videos on YouTube were viewed more than 365 million times in total [9]. In recent years, the injectable antidiabetic drug with weight loss property, branded Ozempic, has gained significant attention on platforms such as TikTok (ByteDance) and YouTube. Between 2018 and 2023, online searches for Ozempic surged in the United States [10]. Celebrity endorsements have driven its popularity, with 100 TikTok videos garnering over 70 million views [11]. However, this trend is concerning as many social media posts focused on the off-label use of Ozempic for weight loss, ignoring the potential health hazards [12]. Analyses of Reddit posts and social media comments have revealed discussions about off-label uses, struggles with insurance coverage, interest in compounded formulations, and unwanted side effects such as insomnia, anxiety, and depression [13,14].

Semaglutide, the active ingredient in Ozempic, was developed in 2012 to treat type 2 diabetes [15]. It is a glucagon-like peptide-1 (GLP-1) receptor agonist. GLP-1 receptors are expressed in many organs (pancreas, gastrointestinal tract, heart, brain, kidneys, lungs, and thyroid). This is associated with the pleiotropy and benefits of semaglutide in type 2 diabetes mellitus, weight loss, and cardioprotection. It can lower blood sugar levels through numerous means, including increasing insulin production, inhibiting glucagon secretion, and slowing gastric emptying [16]. Semaglutide is marketed as Ozempic and Rybelsus for treating diabetes and as Wegovy for chronic weight management. Ozempic and Wegovy are injectable, whereas Rybelsus is an oral tablet.

In 2017, the SUSTAIN (Semaglutide Unabated Sustainability in Treatment of Type 2 Diabetes) 1 trial demonstrated that weekly injections of semaglutide significantly improved body weight as well as glycated hemoglobin (HbA_{1c}) levels in type 2 diabetes patients [17]. The STEP (Semaglutide Treatment Effect in People with obesity) 1 trial published in 2021 showed that semaglutide, combined with lifestyle changes, significantly reduced body weight in overweight or obese nondiabetic patients [18]. These trials and their subsequent trials facilitated the United States Food and Drug Administration (FDA) to approve injectable semaglutide for treating diabetes and weight management. Besides, semaglutide was also approved in Europe [19]. Meanwhile, the PIONEER (Peptide Innovation for Early Diabetes Treatment) 1 trial published in 2019 found that daily oral semaglutide, versus placebo, significantly improved HbA_{1c} levels in type 2 diabetes patients managed by diet and exercise [20]. This supported the FDA approval of oral semaglutide to treat diabetes.

During the development of semaglutide (*la semaine* in translation from French, “week”), researchers sought to increase its duration of action. The half-life of oral semaglutide is approximately 1 week [21]. Ozempic (in strengths of 2 mg/1.5 mL, 2 mg/3 mL, 4 mg/3 mL, and 8 mg/3 mL), Rybelsus (3, 7, and 14 mg), and Wegovy (0.25 mg/0.5 mL, 0.5 mg/0.5 mL, 1 mg/0.5 mL, 1.7 mg/0.75 mL, and 2.4 mg/0.75 mL) have different dosages depending on the treatment purposes and patient characteristics. Ozempic, Rybelsus, and Wegovy are prescription medicines [22]. Common side effects include a slowdown in the digestive process from the stomach, nausea, and vomiting, which can be mitigated by gradually increasing the dose. Semaglutide is associated with increased risks of pancreatitis, gallbladder disease, and retinopathy, including vitreous hemorrhage and vision loss [8,23]. Besides, the rapid decrease in glucose levels can also worsen retinopathy in type 1 diabetes patients. Semaglutide is contraindicated in patients with a personal or family history of medullary or multiple thyroid cancer or endocrine neoplasia syndrome type 2. Serious side effects include abdominal pain, constipation, diarrhea, nausea, vomiting, dizziness, cholelithiasis, cholecystitis, acute myocardial infarction, gastroenteritis, and suicidal ideation [8].

The use of semaglutide, particularly the famous Ozempic, by nonsevere overweight individuals might pose safety issues [24]. Off-label drug use is legal and common, though it means a drug is being used for an unapproved indication or population, at an unapproved dosage, or via an unapproved route of administration [24,25]. Off-label users may have a higher safety risk if they obtain semaglutide via online vendors or beauty spas without a proper medical consultation [26]. With this background, this study aimed to investigate whether YouTube videos mentioned or discussed the side effects and safety concerns of semaglutide. It was hypothesized that full-length videos should be more informative than shorts (limited to 1 minute) and that full-length videos uploaded by YouTube-verified health source channels should be more informative than their counterparts. For readers’

XSL•FO
RenderX

information, a video coming from YouTube-verified health source channels would have an information panel underneath the video stating that it comes "from a channel with a licensed doctor (or health professional)" in a particular country, such as the United States.

Methods

Data Source and Search Strategy

On January 5, 2024, a search was performed on YouTube for semaglutide videos in English. Using Google Chrome with Incognito mode, YouTube was searched with the words semaglutide, Ozempic, Wegovy, and Rybelsus, respectively. For each search word, the first 30 full-length videos (videos without a time limit) and 30 shorts (videos that are no longer than 1 minute) resulting from the search, sorted by relevance, were recorded. The number of 30 videos was chosen according to a recent study, which claimed that very few YouTube users searched beyond the 33rd video [27]. After discounting duplicates and excluding unsuitable videos, a total of 96 full-length videos and 93 shorts were analyzed.

Outcome Measures

We recorded the basic video metrics, such as the duration, number of views, number of comments, number of likes, number of channel subscribers, and the age of the video since upload (number of days until March 14, 2024). The readability and sentiment of the video transcripts were assessed. The quality of video content was evaluated. Further details are described in further sections.

Data Extraction

To evaluate the readability and overall sentiment, video transcripts were generated and analyzed. To evaluate the quality of video content, the entire videos were watched and analyzed.

The video transcripts were generated by Whisper (with the "large" version, edition 20231117), an artificial intelligence automatic speech recognition system developed by OpenAI [28]. It has been used in previous research to transcribe educational videos [29] and had the best performance compared with similar automatic transcription tools [30]. The readability of the transcripts was evaluated by the Flesch Reading Ease (FRE) score [31], calculated via an online platform (Readability Formulas website). In brief, the score ranged from 0 to 100, with 90 to 100 being very easy, 0 to 29 being very difficult, and 60 to 69 being standard. Meanwhile, the sentiment of the transcripts was evaluated by ChatGPT 3.5, an artificial intelligence large language model developed by OpenAI that has been demonstrated to be very effective in sentiment analysis across multiple languages [32]. Referring to the method by Fu et al [32], the prompt was set as "Is the sentiment of this text positive, neutral, or negative? Respond with the sentiment label only." The "temperature" of the ChatGPT model was set at 0 to ensure the consistency of the answers with the least creativity. Temperature is a variable that changes the degree of randomness of the output generated by the model [33].

Next, the quality of video content was evaluated by 3 tools, Global Quality Score (GQS) [34], Modified DISCERN [35], and a custom checklist. Manual evaluations were independently performed by two authors (AWKY and AGA). Disagreements were resolved through mutual discussion. During these evaluations, the overall audiovisual content of the videos, not merely limited to verbal narrative, was examined. The GQS is a 5-point Likert scale designed to evaluate online health information. A score of 1 means "poor quality, poor flow, most information missing, not at all useful for patients," whereas a score of 5 means excellence and high usefulness for patients [34]. Meanwhile, the Modified DISCERN contains 5 evaluative items and gives 1 point for every positive answer and 0 points for negative answer. It was designed to evaluate YouTube videos on health care information [35]. The 5 items are as follows: (1) Are the aims clear and achieved? (2) Are reliable sources of information used? (3) Is the information presented balanced and unbiased? (4) Are additional sources of information listed for patient reference? (5) Are areas of uncertainty mentioned? For readers' information, the Modified DISCERN is based on an original version of DISCERN, which was designed to evaluate written health information and used a 5-point Likert scale to answer 15 questions plus an overall rating [36]. Since GQS and Modified DISCERN could only give a more general evaluation of the videos, a custom 12-point checklist was devised to evaluate the video content based on some specific aspects of side effects and safety concerns related specifically to semaglutide.

The custom 12-point checklist was compiled by the authors' team with reference to Smits and Van Raalte [37]. It recorded whether the following contents were mentioned in the videos or not: (1) form of application (injection, exception: oral for Rybelsus); (2) safe dosage; (3) need for long-term usage, or change in lifestyle and eating habits to avoid rebound back to original weight after drug cessation; (4) serious side effects (eg, retinopathy and pancreatitis); (5) gastrointestinal symptoms (eg, nausea, diarrhea, vomiting, gastric reflux, and gastritis); (6) prevalence or frequency of such side effects; (7) increased risk of aspiration during the induction of anesthesia; (8) contraindications; (9) long half-life (7 days) so that potential side effects persist for multiple days after drug cessation; (10) lack of long-term data; (11) potential alternatives (eg, diet and bariatric surgery); and (12) risk of counterfeit drugs.

Statistical Analysis

Following descriptive analysis of the video contents, 2-sample t tests were performed were performed to evaluate if there were significant differences between the full-length videos and shorts in terms of the mean FRE, GQS, and Modified DISCERN scores, as well as the mean number of mentioned points from the custom checklist. To supplement, the same tests were performed among the full-length videos, to evaluate if there were differences between those uploaded by YouTube-verified health source channels and those without this verification.

Ethical Considerations

Ethical approval was not applicable, as this study only analyzed publicly available data from existing datasets, and results were presented in aggregate that did not contain any identifiable information.

RenderX

Results

The viewing metrics and content quality between full-length videos and shorts are compared in Table 1. All 189 videos (Figure 1) were collectively viewed 45,040,855 times. There was no significant difference in the mean number of views between full-length videos and shorts (288,563.1 vs 188,465.2, *P*=.30). However, full-length videos received thrice the number of comments than shorts on average (669.6 vs 200.4, *P*=.003). Full-length videos were usually older (ie, uploaded earlier) than shorts (468.0 vs 350.0, *P*=.01). The former had better content quality in terms of GQS, Modified DISCERN, and number of mentioned points from the custom checklist than the latter (all *P*<.001). The readability of the transcripts of the 2 types of videos did not significantly differ and both were at the fairly easy level. Meanwhile, 1 full-length video did not have a narration, whereas 16 shorts played music without a narration (Figure 2). Besides, sentiment analysis showed that full-length videos mainly had a neutral tone (n=59), followed by positive (n=24) and negative (n=12) tones. One full-length video did not have a verbal narrative. Meanwhile, shorts mainly had a neutral tone (n=40), rather than positive (n=19) and negative (n=18) tones. There were 16 shorts without a verbal narrative.

Among the full-length videos, those from YouTube-verified health source channels had a higher average view count than their counterparts (Table 2), though the difference did not reach statistical significance (401,867.2 vs 258,746.3, *P*=.41). Readability analysis suggested that the transcripts from health source videos were generally less readable than their counterparts (63.7 vs 73.8, ie, standard vs fairly easy, *P*<.001). However, health source videos had a higher content quality in terms of GQS and Modified DISCERN (both *P*<.001). On average, they also contained a larger number of mentioned points from the custom checklist than their counterparts, though that difference was not significant (3.5 vs 2.7, *P*=.17)

Next, the reporting of the points from the custom checklist was examined. As stated in previous sections, full-length videos were generally more informative than the shorts. Gastrointestinal symptoms and form of application were the 2 mostly reported points among the full-length videos as well as the shorts (Figure 3). Among full-length videos, the most deficient aspect was the lack of mention about an increased risk of aspiration during the induction of anesthesia associated with the use of semaglutide. Only 1 full-length video (1/96) warned the audience about this potential side-effect. Less neglected aspects were the persistence of side effects due to the long half-life of semaglutide (4/96, 4%) and the risk of counterfeit drugs (4/96, 4%). On the other hand, the shorts had generally omitted several important aspects. Apart from the increased risk of aspiration during the induction of anesthesia (1/93), none of the shorts mentioned the prevalence or frequency of side effects, persistence of side effects due to the long half-life, lack of long-term data, and risk of counterfeit drugs.

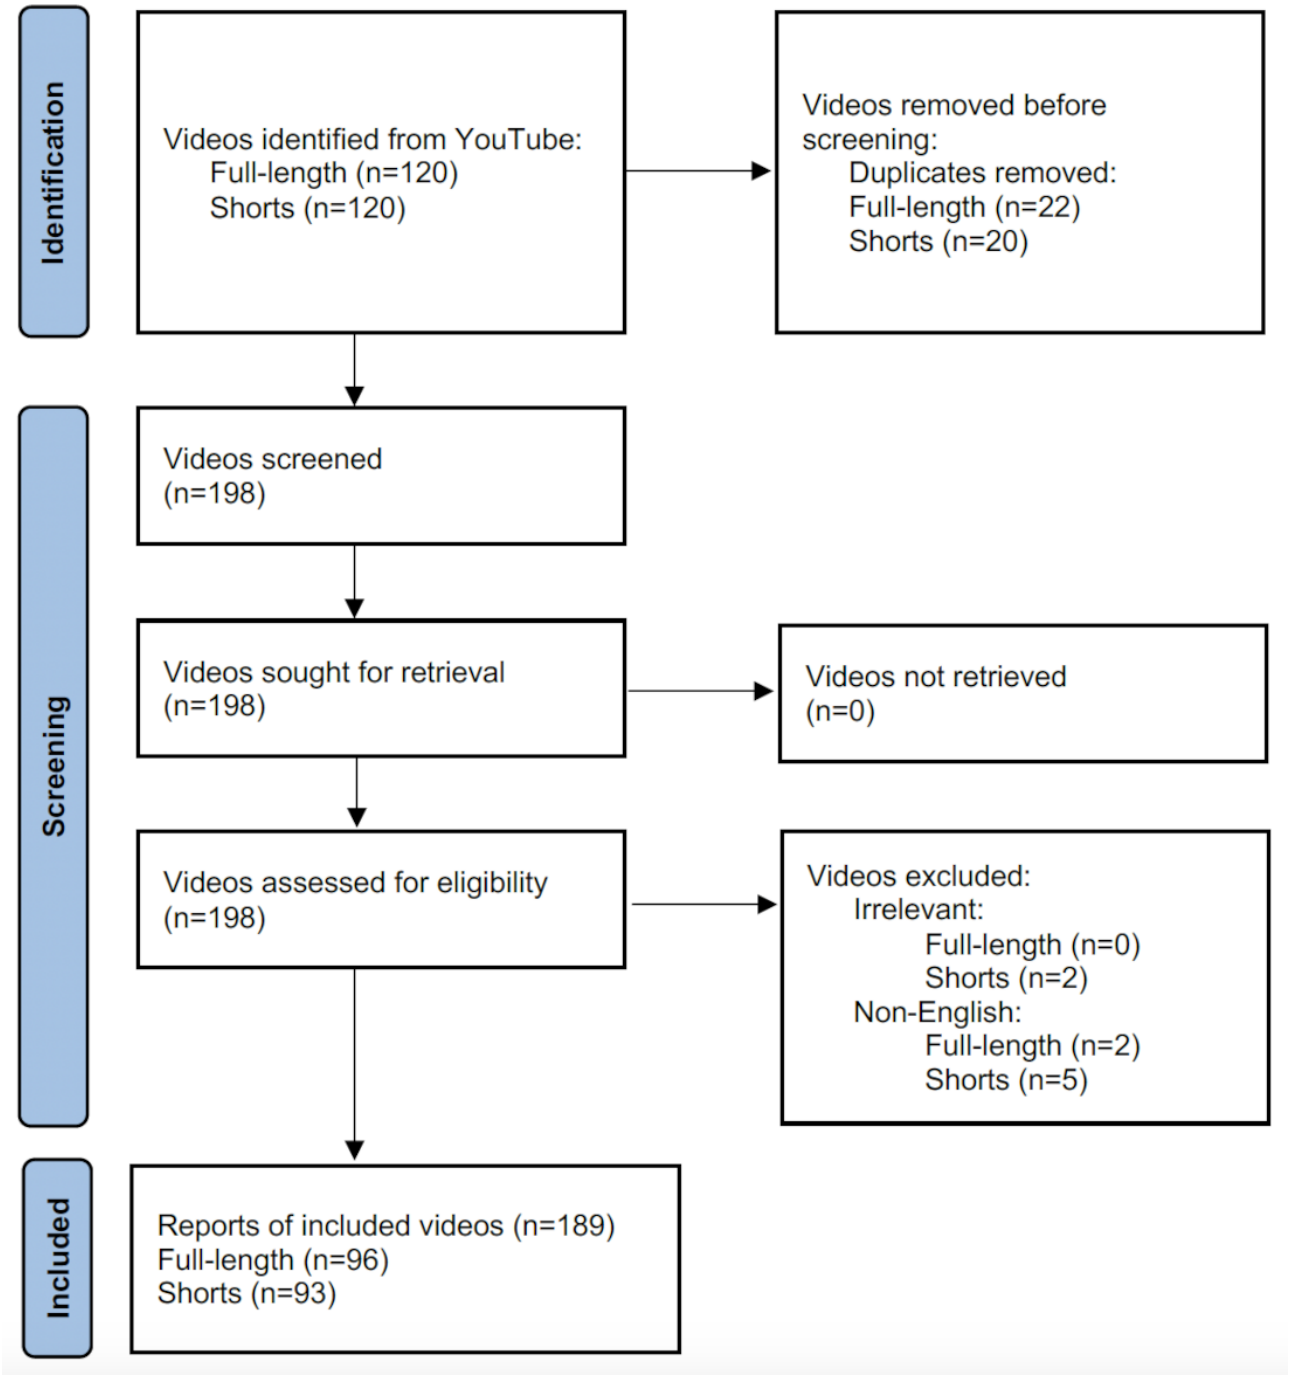

Table 1. Viewing metrics and content quality between full-length videos and shorts.

Metric	Mean (SD)		*P* value
	Full-length videos	Shorts	
Duration (s)	610.5 (542.6)	39.0 (17.2)	<.001
View count	288,563.1 (513,598.3)	188,465.2 (780,376.2)	.30
Comment count	669.6 (1281.0)	200.4 (571.4)	.003
Like count	5363.2 (11,842.7)	7412.4 (39,692.8)	.63
Channel subscriber count	1,721,826.1 (3,500,160.1)	531,761.7 (1,783,695.8)	.004
Video age (days)	468.0 (411.4)	350.0 (152.4)	.01
Flesch Reading Ease score	71.7 (11.6)	72.9 (14.3)	.54
GQS[a] score	2.6 (0.8)	1.1 (0.4)	<.001

Discussion

Principal Findings

This study found that semaglutide videos on YouTube have reached a broad audience. The 189 analyzed videos had a total view count of over 45 million. For comparison, the 98 most viewed YouTube videos on diabetic retinopathy were collectively viewed 1 million times [38]. It implied that these videos might potentially affect the perception and even health care decisions of the general public regarding the use of semaglutide. As expected, full-length videos were generally more informative than shorts. For patient education, shorts would serve better to grab the attention of the patients or make them aware of 1 or 2 particular issues related to semaglutide; whereas selected full-length videos might be more suitable to be incorporated as part of a panel discussion or public forum.

Alarmingly, the videos seldom covered the risk of counterfeit drugs. For instance, the antidiabetic drug, Ozempic, contains semaglutide that is synthesized by yeast fermentation and subsequent synthetic modification [39]. Without proper quality control of the synthetic processes, some falsified Ozempic products were found to contain contaminants such as glass particles and filler substances [39]. Meanwhile, some pharmacies would produce compounded versions of semaglutide to circumvent the patent issue. The high demand, high cost, and limited supply have led to a period of time when some patients and drug providers switched to compounded semaglutide [10]. Subsequently, the FDA stated that the compounded drugs, such as semaglutide sodium and semaglutide acetate, do not have their approval due to lack of testing, may not possess the same drug effect as semaglutide, and may even cause adverse effects (unspecified) [40,41]. Another safety issue of using compounded semaglutide is an increased risk of overdose due to suboptimal drug packaging. A recent case series reported that compounded semaglutide might be dispensed in vials instead of prefilled manufactured injection pens such as those by Ozempic and Wegovy [42]. Vials that contain large volumes of semaglutide and vials dispensed together with subpar syringes might allow for overdose much more easily during self-administration [42]. There seemed to be yet a case series on the overdose of oral semaglutide, but it would be reasoned that compounded semaglutide in the form of tablets for oral intake could have the same increased risk if each tablet did not conform to the amount of semaglutide contained in approved branded semaglutide products such as Rybelsus.

Another not uncommon risk of taking semaglutide that was often neglected by the videos was the risk of aspiration during the induction of anesthesia. One effect of semaglutide is gastroparesis, that is, reduced bowel motility and gastric emptying without any physical obstruction. This would increase the gastric volume and increase the risk of regurgitation and pulmonary aspiration of gastric contents even with the usual recommended fasting time before anesthesia [43,44]. According to a recent study, aspiration of gastric contents accounted for 5% of closed anesthesia malpractice claims in the United States during 2000-2014 [45]. Among these claim cases related to aspiration, 57% (66/115) of patients died and another 14% (16/115) suffered from permanent severe injury [45]. It implied that aspiration during anesthesia was not uncommon, and it could lead to very serious consequences. While medical organizations develop recommendations regarding the use of GLP-1 receptor agonists before operations, the optimal approach to patient data management is still being specified [46,47]. Hence, it is important for researchers and clinicians to conduct subsequent studies to optimize the fasting time and airway management strategy for patients on semaglutide who need to undergo anesthesia.

Although there have been many clinical trials on the efficacy and safety of semaglutide, most of them (if not all) had a study period of up to 2 years (104 weeks) only, such as the STEP, SUSTAIN, and PIONEER trials [37,48]. Since the use of semaglutide could last beyond 2 years and there could be a possibility of life-long usage, a lack of long-term data could mean potential risks yet to be elucidated, such as the discovery of more side effects, and potential development of drug dependence or drug resistance [49,50]. The COVID-19 vaccines

XSL•FO
RenderX

may illustrate the situation of lack of long-term data. After the COVID-19 pandemic began near the end of 2019, pharmaceutical companies put huge efforts into creating vaccines that could lower the infection rate and reduce the symptoms or morbidity. By the end of 2020, at least 10 vaccines have already been introduced into the global market and authorized by governments for emergency use [51]. After several years in use, millions of people vaccinated and billions of doses administered, data have accumulated. By analyzing the retrospective data, researchers have recently found 2 new rare but potentially severe side effects of COVID-19 vaccines, namely acute disseminated encephalomyelitis and transverse myelitis [52]. This new finding may influence the decision-making of some people in the public on whether they should be vaccinated, take a booster, or choose which type of available vaccines to use. In the case of semaglutide, more data besides its weight loss and antidiabetic properties would facilitate better-informed decisions from clinicians and patients. For instance, there were cases reported on the development or recurrence of depression 1 month after taking semaglutide, which was subsequently relieved after discontinuing the drug [53]. On the other hand, a retrospective study that covered over 1.5 million patient records reported that semaglutide users had a lower risk of incident and recurrent suicidal ideation [54]. At the same time, an analysis of over 40,000 user comments posted on social media platforms has found that users of GLP-1 receptor agonists (including semaglutide) felt that the drugs have mixed effects on their mood, anxiety, and insomnia conditions [14]. Patients should be aware of the fact that many weight-loss drugs, mainly appetite suppressants, were withdrawn from the market in the past due to adverse drug reactions [55]. Therefore, in the future when long-term data become available, the safety and side effects of semaglutide could be better assessed and established.

Findings from this study echoed previous studies on Reddit content on Ozempic or semaglutide, in the sense that there is generally a lack of discussion or elaboration on the potential health risks and hazards associated with the use of Ozempic, not to mention its off-label use [12,13]. However, the risks and hazards indeed exist, such as concerns with depression and anxiety raised by social media users on YouTube and TikTok [14]. Therefore, actionable recommendations included better public health awareness campaigns to educate the public on the proper use of Ozempic or semaglutide including the potential side effects and how to manage them. Pharmaceutical companies, governments, and health authorities can organize exhibitions in shopping malls, provide easy-to-understand information on their web pages, and develop user-friendly mobile apps to engage members of the public who are interested. Future research should evaluate the effects of such activities on the knowledge level of the public on semaglutide.

This study has several limitations. First, only the first 30 full-length videos and 30 shorts were initially screened for each search word, rendering a final analysis of 189 videos. This might only represent a small proportion of the entire relevant video collection. Second, only videos in English were analyzed. The themes and foci could be different for videos produced in other languages. Third, errors might exist during computational and manual evaluations. Besides, there was not a detailed analysis of video sources, which might further enhance the findings, for example, whether videos produced by clinicians were more informative than those from general influencers. It was said that there was a tendency for the YouTube algorithm to place more "reliable" videos at the top of the search results [56], hence the presented results in this study might be biased.

Conclusions

The 189 analyzed YouTube videos on semaglutide have attracted more than 45 million views. Full-length videos were much more informative than shorts in terms of side effects and safety issues. The analyzed videos lacked coverage of several important aspects, including the increased risk of aspiration during the induction of anesthesia, the persistence of side effects due to the long half-life of semaglutide, the risk of counterfeit drugs, and the lack of long-term data. Patients should be aware that these videos may not be comprehensive enough even if they were uploaded by YouTube-verified health source channels, and hence cannot replace the consultation from the physician, who may make tailor-made recommendations and treatment plans for each patient.

Abstract

Background: Social media holds an increasingly significant position in contemporary society, wherein evolving public perspectives are mirrored by changing information. However, there remains a lack of comprehensive analysis regarding the nature and evolution of dental health care information on Chinese social media platforms (SMPs) despite extensive user engagement and voluminous content.

Objective: This study aimed to probe into the nature and evolution of dental health care information on Chinese SMPs from 2018 to 2022, providing valuable insights into the evolving digital public perception of dental health for dental practitioners, investigators, and educators.

Methods: This study was conducted on 3 major Chinese SMPs: Weibo, WeChat, and Zhihu. Data from March 1 to 31 in 2018, 2020, and 2022 were sampled to construct a social media original database (ODB), from which the most popular long-text posts (N=180) were selected to create an analysis database (ADB). Natural language processing (NLP) tools were used to assist tracking topic trends, and word frequencies were analyzed. The DISCERN health information quality assessment questionnaire was used for information quality evaluation.

Results: The number of Weibo posts in the ODB increased approximately fourfold during the observation period, with discussion of orthodontic topics showing the fastest growth, surpassing that of general dentistry after 2020. In the ADB, the engagement of content on Weibo and Zhihu also displayed an upward trend. The overall information quality of long-text posts on the 3 platforms was moderate or low. Of the long-text posts, 143 (79.4%) were written by nonprofessionals, and 105 (58.3%) shared personal medical experiences. On Weibo and WeChat, long-text posts authored by health care professionals had higher DISCERN scores (Weibo *P*=.04; WeChat *P*=.02), but there was a negative correlation between engagement and DISCERN scores (Weibo tau-b [τb]=–0.45, *P*=.01; WeChat τb=–0.30, *P*=.02).

Conclusions: There was a significant increase in the dissemination and evolution of public interest in dental health care information on Chinese social media during 2018-2022. However, the quality of the most popular long-text posts was rated as moderate or low, which may mislead patients and the public.

Introduction

Social media usage has been extensively integrated into modern life. As of early April 2024, there were 5.1 billion social media users around the world, equating to 62.6% of the worldwide population [1]. As for Mainland China, active social media users numbered approximately 1.1 billion in January 2024, constituting 74.2% of its total population [2]. Social media provides a platform for everyone to disseminate health knowledge, demonstrate cases, and promote themselves [3]. The general public, especially patients, increasingly turns to social media to obtain health information and join communities that exchange medical experiences [4]. A survey conducted in China revealed that 71.9% of participants obtained health education through the internet, with 30.0% of them frequently seeking health information online [5]. The internet is the most important source of information for patients with cancer, and 80% of them use social media to communicate with others about their condition [6]. The content related to health on social media creates a rich repository of information, dynamically reflecting the public's health perceptions in real time.

The growing reliance on social media for health information is a double-edged sword. On the one hand, social media offers a wealth of readily accessible information and a platform for sharing experiences, enhancing public knowledge and communication. On the other hand, studies have shown that the quality of health information on these platforms is highly variable, which may mislead the public, including patients, and potentially cause adverse outcomes [7,8]. The National Institutes of Health explicitly encourages medical professionals to share accurate health information and curb the spread of misinformation online [9].

Social media as a library for real-world studies has garnered attention from academia. Existing studies have focused on tracking topic trends, analyzing group emotions [10,11], searching for health care development directions, predicting disease spread [12], evaluating network information quality, and highlighting the harm of misinformation dissemination [13,14].

Despite the extensive user engagement and voluminous content in Chinese social media, there remains a conspicuous gap in methodical investigations into dental health care information. This gap is particularly pronounced, given China's unique digital landscape, which is dominated by platforms such as Weibo, WeChat, and Douyin (TikTok) [8,15]. Investigating the information on these platforms could fill this void and provide Eastern insights into contemporary public perceptions and concerns regarding dental health. Although a few studies have surveyed COVID-19–related dental posts on Weibo, primarily focusing on the impact of the pandemic on patients [16,17], there is a lack of comprehensive analyses of information quality and topic trends, possibly due to limitations in research tools.

The application of artificial intelligence (AI) tools has made it possible to analyze and monitor the massive amount of information on social media [18]. Among them, natural language processing (NLP), an important branch of AI, is useful for analyzing social media content for text mining purposes [19]. Another burgeoning branch, sentiment analysis tools, can be used for public opinion analysis, such as epidemic trends [20], willingness for vaccination [10], and even presidential elections [21]. Since the emergence of Chat Generative Pretrained Transformer (ChatGPT), it has also been applied to social media research, such as popular hashtag generation algorithms [22] and the construction of lexica for online pharmacovigilance [23]. AI advancements have increased the popularity of social media research in various industries and provided guidance for their development [3,12].

This study was designed to leverage AI tools to shed light upon the changing patterns and standards of dental health care information on mainstream Chinese social media platforms (SMPs). The collected data were meticulously analyzed to identify evolving trends and assess the quality of information pertaining to dental health care. Additionally, this study probed into the determinants of audience engagement and the influence of social media information, aspiring to trace the shifting contours of public perception and the demand for dental health care. The ultimate goal was to furnish dental health care professionals with actionable insights and strategies to enhance their clinical practice and the quality of doctor-patient interactions.

Methods

Data Sources

This study was conducted on 3 major text-based SMPs in China: Weibo, WeChat, and Zhihu. Data from Match 1 to 31 in 2018, 2020, and 2022 were sampled. Weibo is a microblogging website. The WeChat public platform is a self-media platform based on the short-message service application WeChat. Zhihu is a knowledge question-and-answer (Q&A) community, as well as an original content platform.

Data Extraction

To extract relevant data for this study, a social media scraping program was developed using Python's Selenium module. The inclusion criteria specifically focused on 3 key elements: platform, time, and keywords. The time periods were divided into 3 distinct intervals: March 1-31, 2018; March 1-31, 2020; and March 1-31, 2022. The search for data extraction was conducted using a series of Chinese keywords on April 1, 2023. The translated keywords are presented in Boolean logic format in Table 1 and were divided into 3 predetermined themes (general dentistry, orthodontics, and prosthodontics) based on established classifications of subspecialties within the field of dentistry. The general dentistry section included "dental

XSL•FO
RenderX

fillings," "dental cleaning," "tooth extraction," "root canal treatment," and "teeth whitening." The orthodontics section included "orthodontics," "teeth straightening," "orthodontic treatment," "braces," "dental braces," "get braces," and "retainers." The prosthodontics section included "dental crown," "overlay," "porcelain tooth," "dental implant," "implanted tooth," "tooth veneer," and "porcelain veneer." The bilingual translation table is provided in Table S1 in Multimedia Appendix 1, and the translation was based on Chinese official textbooks and the Chinese edition of authoritative English textbooks [24-26]. These keywords covered a broad spectrum of nearly all commonly used Chinese expressions related to dental practices across various specialties, ensuring that the search was comprehensive and inclusive. Notably, all posts meeting the inclusion criteria were included, irrespective of authorship or topic and without manual intervention. When a post was retrieved, it was automatically assigned to the relevant theme based on the search term. For instance, posts retrieved using the keyword "dental fillings" were classified under the general dentistry theme.

Table 1. Keywords for searching posts (translated from Chinese).

Theme	Keywords
General dentistry	"dental fillings" OR "dental cleaning" OR "tooth extraction" OR "root canal treatment" OR "teeth whitening"
Orthodontics	"orthodontics" OR "teeth straightening" OR "orthodontic treatment" OR "braces" OR "dental braces" OR "get brace" OR "retainer"
Prosthodontics	"dental crown" OR "overlay" OR "porcelain tooth" OR "dental implant" OR "implanted tooth" OR "tooth veneer" OR "porcelain veneer"

Weibo's open application programming interface (API) allowed access to all content that met the inclusion criteria. In contrast, for WeChat and Zhihu, we could rely only on the built-in search functions, which do not provide access to all the data. Zhihu required searches based on time conditions within the website. For the WeChat public platform, Sogou's WeChat search was conducted to retrieve the top 10 pages of posts based on the website's own sorting logic, representing the content that people were most likely exposed to.

The exclusion criteria were primarily based on 4 aspects. "Duplicated" content referred to posts that were entirely identical due to duplicate publication, plagiarism, or other similar reasons. Only the earliest published post was retained, and the others were removed. "Irrelevant" content referred to posts in which dental-related keywords were mentioned only briefly, while the main content focused on unrelated subjects. "Unavailable" content referred to posts where the title or abstract was accessible but the full text was no longer available, possibly due to voluntary removal or deletion by the platform. Finally, "meaningless" content included posts that were composed of incoherent or garbled text consisting of nonsensical strings of words or symbols without any thematic relevance. Upon data collection, the content from the 3 SMPs was rigorously screened according to the exclusion criteria. Posts that could potentially disrupt the integrity of the subsequent analysis were removed, and the remaining posts were included to construct a social media original database (ODB).

Database Construction

Following data collection and screening based on the inclusion and exclusion criteria, the ODB was constructed. Posts with 600 characters or more were defined as "long-text posts." Previous studies suggest that long-text posts tend to provide more comprehensive information and exhibit higher engagement levels [27]. The top 20 long-text posts with the highest level of popularity each month on the three platforms were selected to establish an analysis database (ADB) for lexical analysis with NLP tools and information quality assessment.

Evaluation Strategy

Preliminary analysis of the ODB data involved capturing author information and popularity indicators for each platform, including the number of likes or reads. The metric for popularity varied by platform. For Weibo and Zhihu, the number of likes was used. For WeChat, the number of reads was used, as WeChat users tend to use "like" functions less frequently. The top 20 long-text posts with the highest levels of popularity during each observation period were selected from each platform, totaling 180 posts constituting the ADB for text mining and information quality evaluation. The classification of author account types followed subsequently and was based primarily on usernames. Specifically, accounts with names containing medical-related terms, such as "doctor," "dentist," "hospital," or "clinic," were classified as health care professionals, whereas those without such identifiers were categorized as non–health care professionals.

Text mining analysis and information quality evaluation were conducted on the ADB. NLP tools were used for text mining analysis. Using the Jieba segmentation tool, the first step involved cleaning the text data by removing punctuation, converting all text to lowercase, and eliminating common Chinese stop words, such as "of." The cleaned text was then tokenized into individual words, or tokens, to facilitate the analysis of word frequency across the entire ADB. Python's Counter module was used to compile a frequency distribution of the keywords. The most frequently mentioned words were visualized as word clouds, and the frequencies of the top 30 words for each period or platform were visualized as heatmaps. The font size of the word cloud and the color depth of the heatmap represented the frequency of word occurrence, providing a clear representation of the prevalent topics and their temporal variation. For information quality evaluation, the DISCERN questionnaire (Multimedia Appendix 2), which is widely used in research on the quality of health material information online [28,29], was used to assess the reliability of health material and the quality of information for treatment plan selection. The DISCERN score was rated on a 5-point Likert

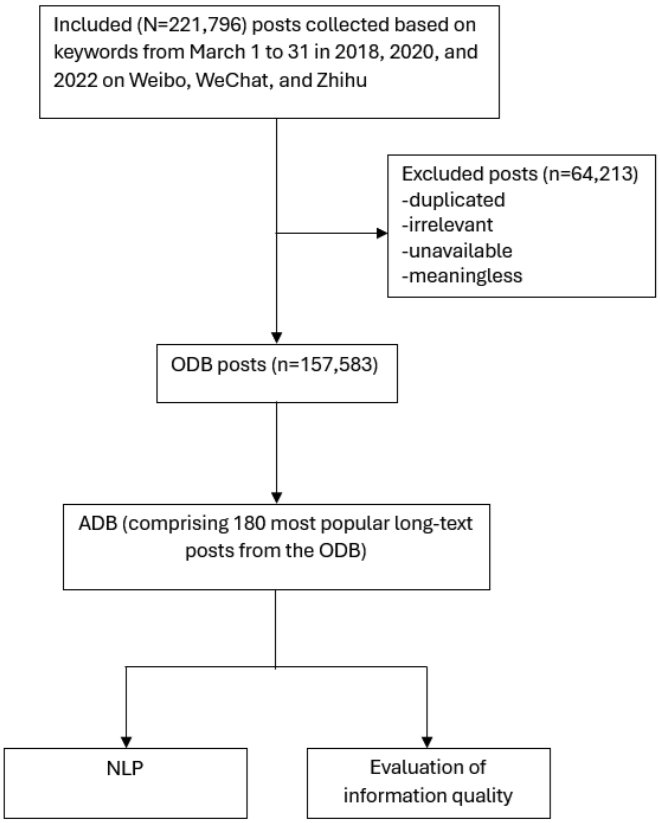
XSL•FO
RenderX

scale, with 1 indicating low quality, 5 indicating high quality, and 3 indicating moderate quality [30]. To ensure the objectivity of evaluation, all posts were anonymized during the review and quality assessment process. The determination of account type was conducted separately from the quality scoring, ensuring that the account type did not influence the quality assessment. Given the greater complexity of the DISCERN information quality assessment, this work was conducted by 2 practicing dental professionals following the Cohen kappa consistency test. Among the 180 long-text posts in the ADB, 18 (10%) were randomly selected for independent assessment by 2 evaluators, resulting in a Cohen kappa coefficient of 0.84, indicating reliable consistency between the results of the 2 evaluators.

Statistical Analysis

Statistical analysis was performed using SPSS software version 25 (IBM Corp). Descriptive results are presented as the median (25th-75th percentile) for quantitative data. The Shapiro-Wilks test and the Levene test were performed to determine the normality and homogeneity of variance, respectively. The Mann-Whitney U test and the Kruskal-Wallis test, followed by Bonferroni correction, were used to compare nonparametric data among the groups. The Kendall tau-b (τb) correlation coefficient was calculated to evaluate the potential relationships between the parameters. The significance level was set at $P<.05$.

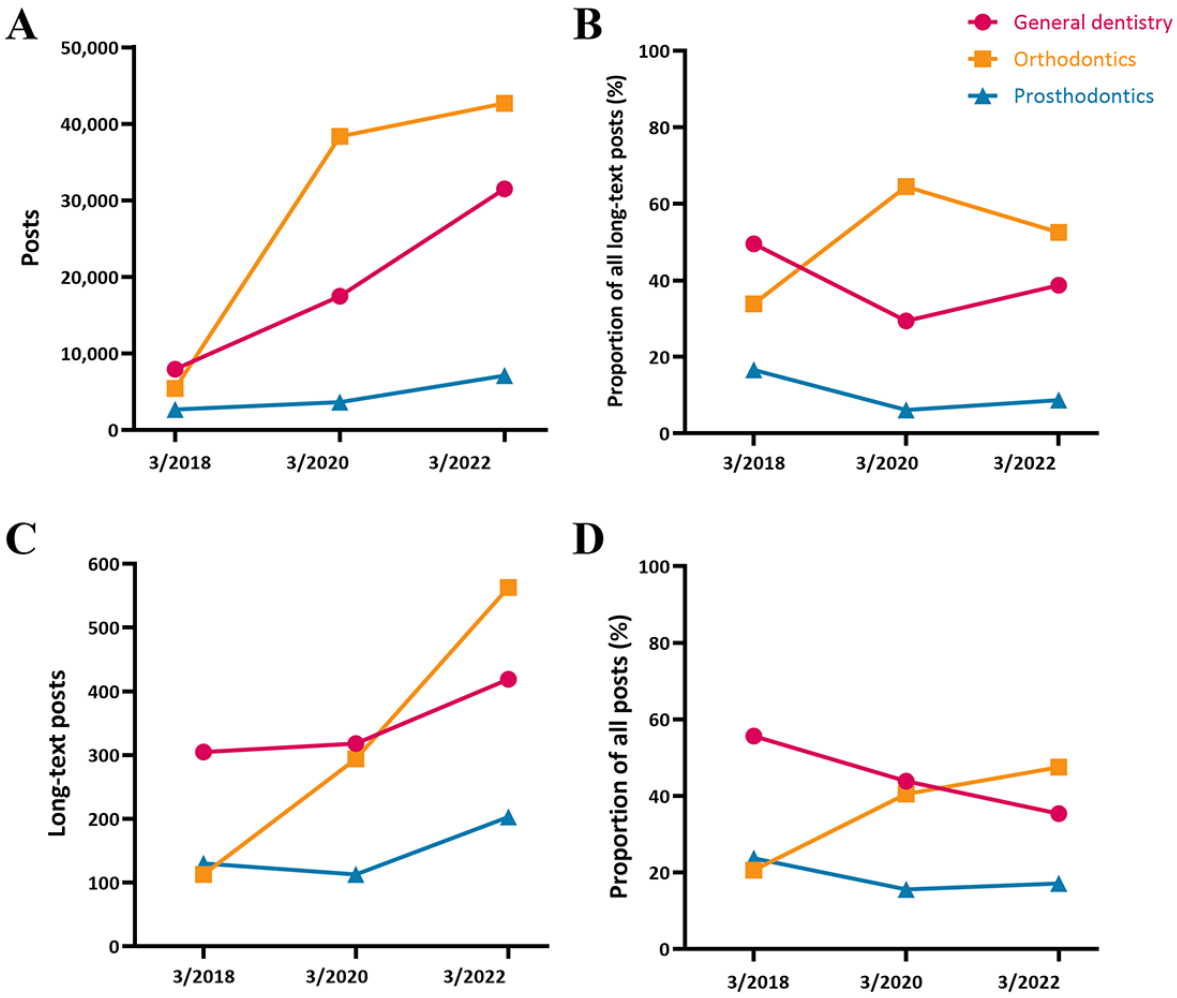
Ethical Considerations



This study did not seek ethical approval, as it exclusively analyzed publicly available data from SMPs, which were voluntarily shared by users in the public domain. All data has been deidentified; account information collected was used solely for research analysis, and relevant results are presented in aggregate to ensure that no personally identifiable information is disclosed.

Results

Post Details



The research methodology is depicted in Figure 1. According to the search keywords, we retrieved a total of 220,869 Weibo posts. After applying the exclusion criteria, 64,039 (29%) posts were deleted, and the remaining 156,830 (71%) posts were included in the ODB. Among Weibo posts, 2458 (1.6%) were long-text posts. The distribution and proportion of posts and long-text posts for each theme in each observation period are shown in Table S2 in Multimedia Appendix 1. Results showed that over time, there has been significant growth in the content related to dental health care on Weibo, with the number of posts increasing by more than 4 times (Figure 2A). In terms of themes, in 2018, there was a greater proportion of posts and long-text posts discussing general dentistry–related topics, accounting for 49.5% (n=7952) and 55.7% (n=305) of the total, respectively. In 2022, 52.5% (n=42,701) of the posts and 47.5% (n=563) of the long-text posts discussed orthodontics topics (Figure 2D), surpassing the proportion of general dentistry topics. In addition, 543 (0.34%) posts from WeChat and 210 (0.13%) posts from Zhihu were included in the ODB.

Figure 1. Overview of data-processing flowchart. ADB: analysis database; NLP: natural language processing; ODB: original database.

XSL•FO
RenderX

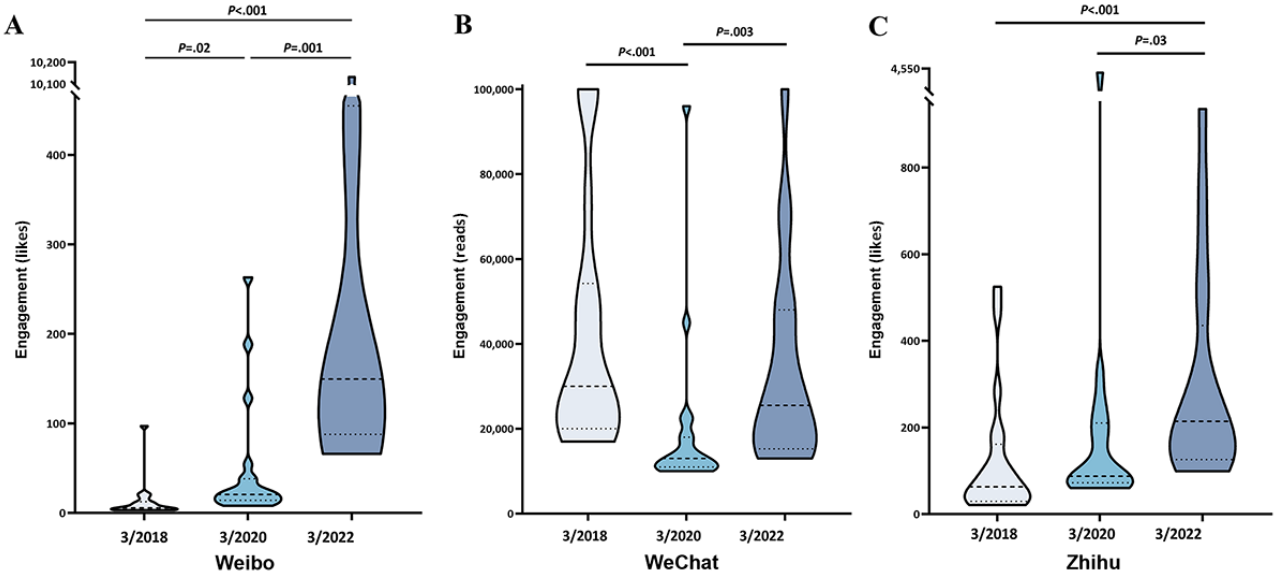
Figure 2. Numbers and proportions of Weibo posts (A, B) and long-text Weibo posts (C, D) on each theme in March 2018, 2020, and 2022.

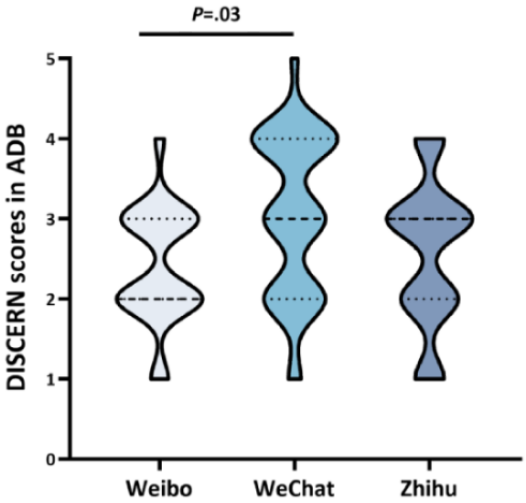
The ADB comprised 180 most popular long-text posts (n=60, 33.3%, posts from each platform) during the observation period. There were significant differences in the engagement of long-text posts published on Weibo, WeChat, and Zhihu between March 2018, 2020, and 2022 (P<.001; Figure 3 and Table S3 in Multimedia Appendix 1). The median (IQR) of likes on Weibo increased from 5.5 (IQR 3.25-12.5) in 2018 to 149.5 (IQR 87.75-454.75) in 2022. Similarly, the median number of likes on Zhihu increased from 63 (IQR 29.25-161.25) in 2018 to 214 (IQR 126-435.5) in 2022. In contrast, the median (IQR) of WeChat reads was 30,000 (IQR 20,000-54,250) in 2018, decreased to 13,000 (IQR 11,000-18,000) in 2020, and then increased to 25,500 (IQR 15,250-48,000) in 2022. Interestingly, 143 (79.4%) long-text posts were written by non–health care professionals, including patients and some medical self-media accounts. In terms of topics, there were 105 (58.3%) posts about personal medical experiences, a number significantly greater than the content of health education and popular science provided by dental health care professionals.

In the ADB, the median (IQR) of the DISCERN score for WeChat long-text posts was 3 (IQR 2-4), that for Weibo was 2 (IQR 2-3), and that for Zhihu was 2 (IQR 2-3). There was a significant difference in the DISCERN scores between WeChat and Weibo (P=.03; Figure 4 and Table S4 in Multimedia Appendix 1). The scores for each question in the DISCERN questionnaire corresponding to each platform are presented in Table S5 in Multimedia Appendix 1. Among the 180 long-text posts in the ADB, only 37 (20.6%) were authored by dental health care professionals, while the DISCERN scores of these long-text posts on Weibo and WeChat were significantly higher than those of long-text posts written by non–health care professionals. Specifically, for Weibo the median (IQR) of the DISCERN score of health care professionals' long-text posts was 3 (2.5-3.5), while that of non-health care professionals' was 2 (2-3); for WeChat the median (IQR) of the DISCERN score for health care professionals' long-text posts on WeChat was 4 (IQR 4-4), while that for non–health care professionals was 3 (IQR 2-3). The difference was statistically significant (Weibo P=.04; WeChat P=.02). Furthermore, there was a significant negative correlation between information quality (DISCERN score) and engagement (Weibo τb=–0.45, P=.01; WeChat τb=–0.30, P=.02). No similar significant negative correlation was observed for the Zhihu long-text posts.

XSL•FO
RenderX

Figure 3. Violin plots of engagement indicators for long-text posts on Weibo (A), WeChat (B), and Zhihu (C) in March 2018, 2020, and 2022.





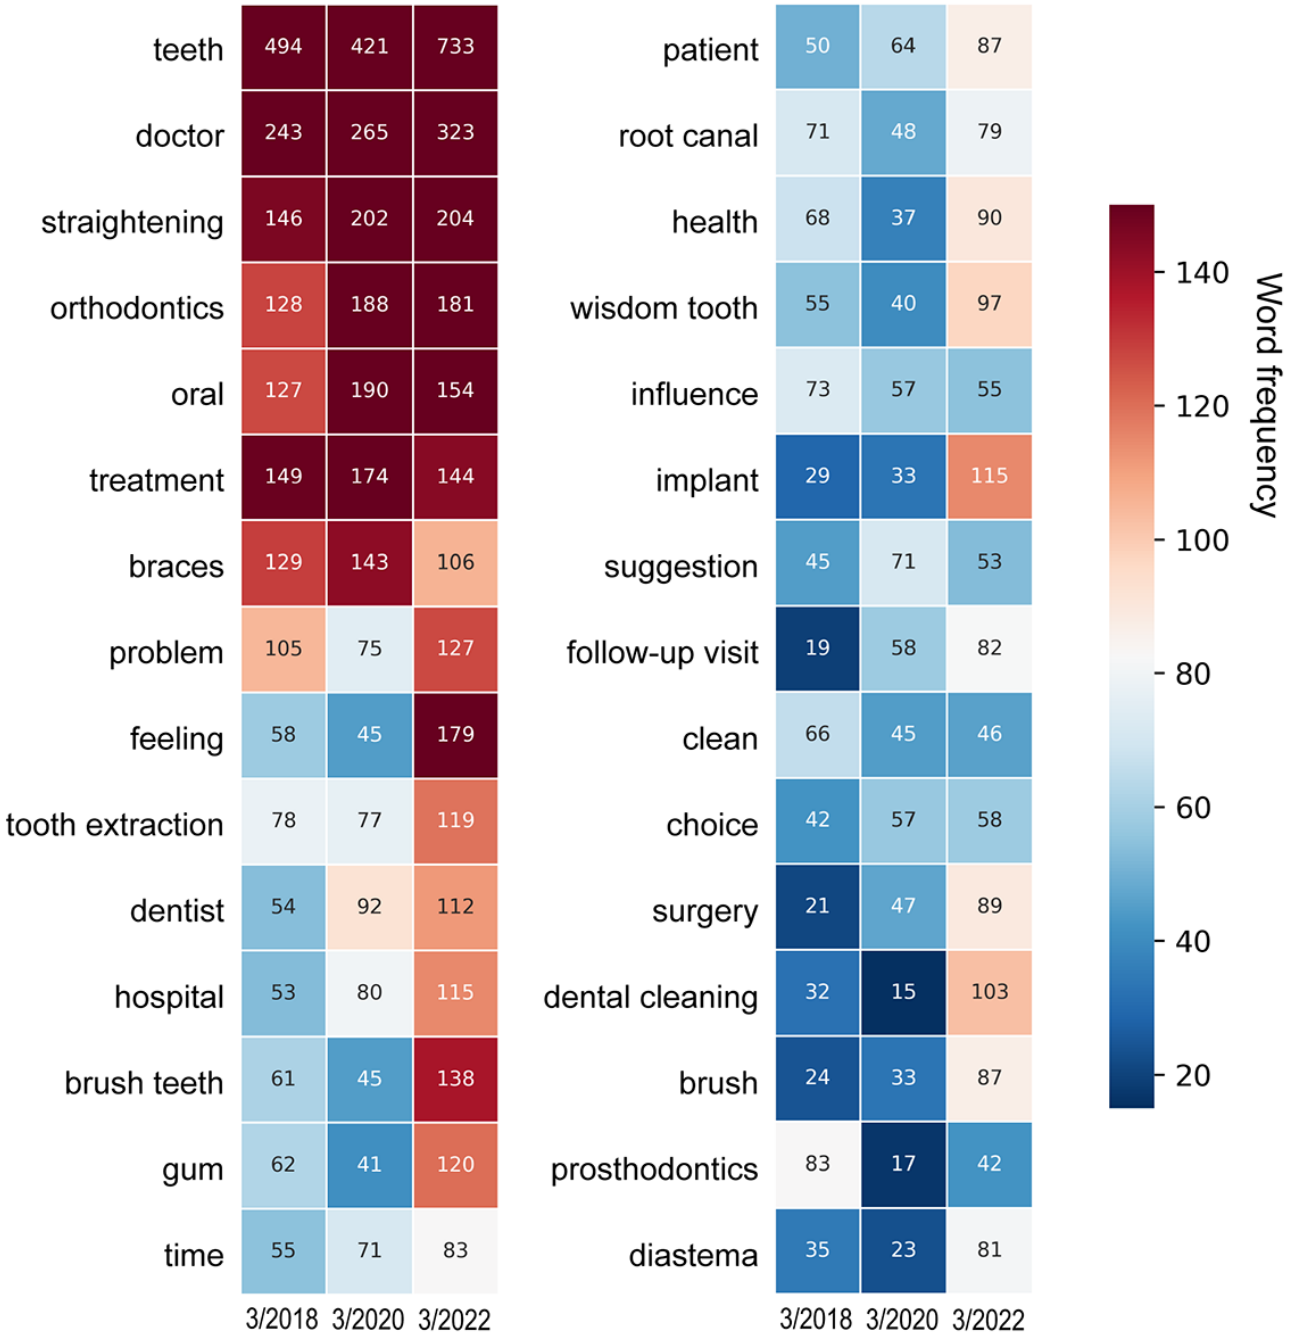


Figure 4. Violin plot of the DISCERN scores of long-text posts on the 3 SMPs in the ADB during the observation period. ADB: analysis database; SMP: social media platform.

Text mining analysis of the ADB using NLP tools was visualized as word clouds and heatmaps of the 3 observation periods (Figure 5) and the 3 platforms (Figure 6). For optimal readability, the bilingual word cloud figures are shown in Multimedia Appendices 3 and 4. The frequencies of the top 30 words in each time period and platform are presented in Tables S6 and S7, respectively, in Multimedia Appendix 1. In the word clouds, “teeth” and “doctor” were the most frequently mentioned core keywords. The most prominent terms in the 2018 word cloud were “straightening,” “braces,” “orthodontics,” “prosthodontics,” “tooth extraction,” “root canal,” “health,” and “metal” (crown). In the 2020 word cloud, the most prominent terms were “straightening,” “orthodontics,” “braces,” “tooth extraction,” “invisible,” “deciduous teeth,” “follow-up visit,” and “retention.” In the 2022 word cloud, the most prominent terms were “straightening,” “orthodontics,” “feeling,” “brush teeth,” “gums,” “tooth extraction,” “implant,” and “dental cleaning.” This trajectory suggested that over time, orthodontics and tooth extraction have consistently been the most mentioned terms in Chinese social media in regard to dental health care. However, it could be seen from the word clouds and heatmaps that there was a shift from topics such as root canal treatments and metal crown restoration, which were discussed more often in 2018, to topics such as teeth brushing, gingival health, and dental cleaning by 2022, indicating the concentration on periodontal health and early prevention of dental diseases. There was also an increase in discussions related to dental implantation and orthognathic surgery. The most prominent terms in the Weibo word cloud were “straightening,” “orthodontics,” “wisdom tooth,” “tooth extraction,” and “gum.” The most prominent terms in the WeChat word cloud were “straightening,” “brush teeth,” “health,” “deciduous teeth,” “orthodontics,” and “gum.” In Zhihu, the most prominent terms were “orthodontics,” “braces,” “feeling,” “straightening,” “tooth extraction,” and “follow-up visit.”

Discussion

Principal Findings

This study extracted dental health care-related content from Weibo, WeChat, and Zhihu for March 2018, 2020, and 2022 and constructed an ODB. We also constructed an ADB consisting of the most popular long-text posts on each platform. By analyzing the nature, themes, public engagement, information quality, and word frequency, this study tracked the evolution of Chinese social media content related to dental health care. In the field of dentistry, previous studies have investigated SMPs, such as Facebook, Instagram, and YouTube, analyzing topic trends and evaluating the adequacy of these platforms as patient sources of information or education [31-33]. Graf et al [32] explored the nature and potential attitude differences in German orthodontic content on Twitter and Instagram, finding “getting braces” and “getting braces removed” to be the most crucial events for orthodontic patients, and Instagram contained more posts with positive emotions. Yahya et al [34] studied the 63 most viewed videos on YouTube related to miniscrew anchorage and found that the information quality of videos uploaded by dental professionals is not perfect, especially in terms of treatment duration, maintenance, and costs. Similarly, Samur et al [35] reported that the reliability and information quality of content related to facial trauma on SMPs are generally low, highlighting the need for caution when

XSL•FO
RenderX

recommending SMPs as a source of facial trauma–related information. To the best of our knowledge, similar systematic research on dental health care information on Chinese SMPs has not been reported in the literature.

Our findings revealed significant growth, by more than 4 times, in Weibo posts concerning dental health care from 2018 to 2022, with the fastest increase observed in the discussion of orthodontics, surpassing general dentistry content since 2020. The long-text posts with the highest engagement on Weibo and Zhihu platforms in the ADB also displayed an upward trend. SMPs plays a progressively significant role in people's lives [36], and our data confirmed that the amount of dental health care–related content on Chinese SMPs is also steadily increasing. Yang et al [37] reported that Instagram accounts created by oral and maxillofacial surgery residency programs increased exponentially from the period of the 7 months from June to December 2020 compared to the 18 months from December 2018 to May 2020. This indirectly reflected the increasing trend of dental health care information on US SMPs, which is consistent with our results.

In the ADB, which consisted of the most popular content on the 3 SMPs, 79.4% of the long-text posts were written by individuals without a health care background, and 58.3% shared personal medical experiences. This finding was consistent with the study by Samur et al [35], who found that personal experience–based content posted by laypersons receives more interactions. This phenomenon aligns with the theories of cognitive dissonance and selective exposure: people are inclined to consume content that is more similar and relatable to them [38,39]. It is worth noting that long-text posts authored by health care professionals received significantly higher DISCERN scores, indicating superior information quality. Nonetheless, these long-text posts were not rewarded with the same level of engagement as those written by nonprofessionals. Furthermore, there was a negative correlation between the DISCERN scores and engagement observed on Weibo and WeChat, suggesting that high-quality information may not generate a larger audience. Similar trends were observed in the study by Hegarty et al [40], who found that the most viewed YouTube videos are less helpful. However, a study by Kovalski et al [41] on oral leukoplakia–related content showed that more reliable videos of higher quality receive more likes and have higher viewing rates and interaction indices. Studies indicate that misinformation often features sensational headlines that are easy to understand without deep engagement or critical thinking. These posts quickly capture attention, eliciting strong emotional responses that prompt users to like, comment, and share [9,42]. The positive feedback loop of social media algorithms amplifies the spread of low-quality content, indirectly suppressing accurate, evidence-based, high-quality information and creating information silos [43].

Peek et al's [44] guidelines for mental health education and advocacy noted that using language that is more accessible to the public instead of medical jargon can make popular science even more popular. However, in the study by Yahya et al [34] on 31 videos uploaded by dental professionals about miniscrew anchorage on YouTube, only 2 videos avoided using technical terms. The remaining videos all used them, with 80.7% failing to provide explanations. The excessive use of technical terms, obscure and complicated principles, and stagnant formatting in health education materials may meet the requirements of the DISCERN questionnaire and thus can elicit high information quality scores. However, several studies have revealed that this may result in a loss of readers' interest and psychological resonance [35,39]. Conversely, using psychologically assisted writing techniques that foster affinity may prove more effective in attracting readers and achieving better health education outcomes. To effectively disseminate health care knowledge, dental professionals should improve writing methodologies, while ensuring the accuracy and high quality of the evidence-based information conveyed. For instance, incorporating patient-centered medical experiences and visual materials can attract more readers and stimulate discussions. This could ultimately make a greater impact and benefit a larger audience. In addition to health care professionals, governments and health departments should take measures to promote the dissemination of high-quality health information online, while enhancing the public's critical-thinking skills to discern true from false information and make informed decisions [9,13]. Technology platforms should transparentize and optimize recommendation algorithms and regulate the quality of health [9,42].

Oliveira et al [45] performed 2 searches on Twitter using the keywords "dentist" and "teeth" and generated a word cloud based on the collected tweets, finding that the most commonly used terms are "third molar" and "orthodontic appliance." On this basis, they determined that the most common dental needs during the COVID-19 pandemic were pain, urgencies, and orthodontic follow-ups. Graf et al [32] showcased word clouds of orthodontically posts with different sentiments. Positive posts revolved around the effectiveness of orthodontic treatment and the excitement of wearing or removing braces, while negative posts covered complaints about appointments, waiting times, pain, and side effects during orthodontic treatment. In this study, word clouds were generated for 3 SMPs during the observation period. We found that "teeth" and "doctors" are consistently the core subjects in the field of dental health care on Chinese SMPs. In line with the findings of Oliveira et al [45], orthodontics and tooth extraction have been the most discussed topics across different years and platforms, suggesting that the most prevalent keywords on Chinese SMPs are similar to those in other languages. Moreover, there has been a noticeable shift from topics such as endodontic treatment or dental crown restoration in 2018 to a stronger emphasis on topics such as periodontal maintenance and early prevention by 2022. This is indicated by the increased discussions around teeth brushing, gingival health, and dental cleaning. Additionally, topics such as dental implantation and orthognathic surgery have gradually gained popularity in the word clouds, suggesting that concepts in these areas are becoming more universally accepted by the public. Patients interest has gradually evolved from basic dental treatments to functional dentofacial aesthetics and preventative care.

This study demonstrates the increase in the quantity and engagement of dental health information on Chinese social media from 2018 to 2022, emphasizing the importance of

XSL•FO
RenderX

offering high-quality information online in the digital age. Additionally, we explored changes in public interest in dental topics, providing insights into the evolving awareness of patients. This highlights the need for dental health care providers to supplement evidence-based information, particularly on topics of interest to the general public. They should take measures to improve the popularity of online scientific materials and mitigate the impact of low-quality information.

Limitations

This study has a few limitations. First, there are constrained capabilities of NLP tools when evaluating complex indicators, such as DISCERN scores, across large datasets, as well as identifying meaningless content, such as bot-generated text. Consequently, this task was performed manually as a substitute, which inevitably restricted the scale of relevant data analysis, necessitating the use of sampling methods rather than analyzing the entire dataset. Second, platforms such as WeChat and Zhihu do not provide a straightforward way to access comprehensive data, prompting us to use alternative strategies for collecting a representative sample. We also note that including data from 2019 and 2021 could have resulted in more continuous and reliable sampling points. Third, this study was retrospective in design, while, given the dynamic nature of social media, some users may have hidden or deleted previously published posts, potentially introducing bias into the findings. Finally, expanding the scope of this study to include data from additional sources, such as government agencies or dental associations, would facilitate a comparative analysis. Future research could focus on these aspects.

Conclusion

During 2018-2022, despite the increase in the dissemination and evolution of public interest in dental health care information on Chinese social media, the quality of the most popular long-text posts was rated as moderate or low, which may mislead patients and the public. These findings could yield insights for dental practitioners, investigators, and educators into patients' evolving perceptions and interests in the era of social media. We also emphasize the importance of enhancing the provision of high-quality and popular health information on Chinese SMPs.

Abstract

Background: The COVID-19 pandemic intensified the challenges associated with mental health and substance use (SU), with societal and economic upheavals leading to heightened stress and increased reliance on drugs as a coping mechanism. Centers for Disease Control and Prevention data from June 2020 showed that 13% of Americans used substances more frequently due to pandemic-related stress, accompanied by an 18% rise in drug overdoses early in the year. Simultaneously, a significant increase in social media engagement provided unique insights into these trends. Our study analyzed social media data from January 2019 to December 2021 to identify changes in SU patterns across the pandemic timeline, aiming to inform effective public health interventions.

Objective: This study aims to analyze SU from large-scale social media data during the COVID-19 pandemic, including the prepandemic and postpandemic periods as baseline and consequence periods. The objective was to examine the patterns related to a broader spectrum of drug types with underlying themes, aiming to provide a more comprehensive understanding of SU trends during the COVID-19 pandemic.

Methods: We leveraged a deep learning model, Robustly Optimized Bidirectional Encoder Representations from Transformers Pretraining Approach (RoBERTa), to analyze 1.13 billion Twitter (subsequently rebranded X) posts from January 2019 to December 2021, aiming to identify SU posts. The model's performance was enhanced by a human-in-the-loop strategy that subsequently enriched the annotated data used during the fine-tuning phase. To gain insights into SU trends over the study period, we applied a range of statistical techniques, including trend analysis, k-means clustering, topic modeling, and thematic analysis. In addition, we integrated the system into a real-time application designed for monitoring and preventing SU within specific geographic locations.

Results: Our research identified 9 million SU posts in the studied period. Compared to 2019 and 2021, the most substantial display of SU-related posts occurred in 2020, with a sharp 21% increase within 3 days of the global COVID-19 pandemic declaration. Alcohol and cannabinoids remained the most discussed substances throughout the research period. The pandemic particularly influenced the rise in nonillicit substances, such as alcohol, prescription medication, and cannabinoids. In addition, thematic analysis highlighted COVID-19, mental health, and economic stress as the leading issues that contributed to the influx of substance-related posts during the study period.

Conclusions: This study demonstrates the potential of leveraging social media data for real-time detection of SU trends during global crises. By uncovering how factors such as mental health and economic stress drive SU spikes, particularly in alcohol and prescription medication, we offer crucial insights for public health strategies. Our approach paves the way for proactive, data-driven interventions that will help mitigate the impact of future crises on vulnerable populations.

KEYWORDS

substance use; social media; deep learning; Robustly Optimized Bidirectional Encoder Representations from Transformers Pretraining Approach; human-in-the-loop; COVID-19

Introduction

Overview

Substance use (SU) is a pressing public health issue in the United States, with 58.7% of Americans aged ≥12 years using tobacco, alcohol, or illicit drugs in 2020, with an annual increase of 3.8% [1]. This includes 50% alcohol users, 18.7% tobacco users, and 13.5% illicit drug users [1]. The consequences of SU, such as deteriorating health and increased crime, have led to a significant rise in drug overdose deaths, reaching >91,000 in 2020 and >106,000 in 2021 [2]. The economic cost is substantial, with an estimated US $249 billion for alcohol misuse and >US $193 billion for illicit drug use annually [3]. The financial and health repercussions of SU demand a strategic focus on prevention research. Allocating resources to explore and counteract the causes of drug use can lead us toward a healthier and more economically resilient society.

Background

The year 2020, commonly referred to as the COVID-19 year, holds historical significance for health care researchers due to the emergence of the deadly coronavirus. The COVID-19 pandemic exhibited a profound connection with preexisting SU and mental health issues [4-6]. Various consequences, such as economic instability, social isolation, bereavement, and restricted access to health care services, escalated anxiety and stress levels among the population [7-10]. According to the Centers for Disease Control and Prevention, data as of June 2020 revealed that 13% of Americans reported initiating or intensifying SU as a means of coping with stress or emotions related to COVID-19 [11]. The Overdose Detection Mapping Application Program reports indicated an 18% rise in drug overdoses in the early months of the pandemic compared to the same period in 2019 [12]. Several other studies [13-15] also highlighted that changes in drug availability contributed to a rise in deaths related to illicit opioid use; for instance, if heroin became less accessible, individuals might resort to the more potent fentanyl.

Simultaneously, the COVID-19 pandemic led to internet use of up to 70% [16], leading to a record 11.1% growth in Twitter's (subsequently rebranded X) user base in 2020. This surge in social media engagement, while providing a vital connection for many, has also been directly linked to an increase in SU [17]. Research studies [18-22] have indicated the negative impacts of social media on mental health, including increased anxiety, depressive symptoms, and psychological burdens related to COVID-19, which have been correspondingly linked to an increase in SU as individuals seek coping mechanisms. Notably, previous studies [23-27] have also shown a strong correlation between social media use and SU, with evidence of users being influenced to use substances by their peers' behavior, such as tagging their social connections in their posts [26,27]. A few research studies [23,25] provide evidence that higher levels of exposure to substance-related content tend to develop positive norms and attitudes toward alcohol and drug use. Likewise, a study also showed that adolescents who are regularly active on social media have a greater likelihood of subsequent tobacco or cannabis use initiation [24]. In our research, we aim to identify these gaps in the knowledge of SU during the COVID-19 pandemic by analyzing social media content and making a comparison with pre- and postpandemic years. We achieve this through a deep learning model alongside various statistical methods. By comprehending the findings, the ultimate goal is to support public health sectors to develop more effective prevention and intervention strategies to control and prevent SU during global crises.

Related Studies

The onset of the COVID-19 pandemic has notably intensified global research on drug crises. Numerous studies [6,7,28-50] have examined the intersection of drug use and the pandemic's societal impacts. These investigations commonly revealed a significant correlation between the pandemic and shifts in SU patterns, impacting both people with or without SU disorder (SUD). Various studies [6,28,36,37] evidenced that the disruption in health care services during the COVID-19 pandemic period primarily impacted people with SUD and was thus linked to higher abuse of substances. However, many of those research studies relied on data from small cohorts [18,22,29,30] that predominantly used methodologies such as surveys or interviews for data collection. Few studies [30,35,39-41,47,48,51] have used social media data to explore SU during the pandemic. However, the scope of such studies often remains limited to peak pandemic periods and typically focuses on specific types of drugs, such as alcohol, tobacco, or opioids. Only 2 of the studies [14,52] accounted for multiple drug types (that are mostly consumed) to study the correlation between COVID-19 and use of substances, but they still did not consider other drug types (that are less widely used) to check if the use was altered during the global crisis. Likewise, most research only accounted for the peak pandemic period to study the SU trend during COVID-19. Only the study by Omare et al [47] accounted for the prepandemic period (2016-2020) as the baseline to compare the SU trend before the COVID-19 pandemic. Essentially, it established 2 prepandemic baselines, that is, 2016 to 2018 and 2018 to 2019, and compared SU trends over the studied period. However, it did not account for the postpandemic period or whether the SU was altered due to the consequences of COVID-19. This highlights a gap in the literature, underscoring the need for more expansive research that covers various substance types and multiple time frames to better understand the long-term impacts of the pandemic on drug use patterns.

Prominent national agencies such as the National Survey on Drug Use and Health [1], the National Institute on Drug Abuse

XSL•FO
RenderX

(NIDA) [Centers for Disease Control and Prevention [2], and the Substance Abuse and Mental Health Services Administration [50] routinely perform national-level analyses of drug use. Traditionally, these reports are based on survey methodologies, which may involve a relatively limited participant pool. The COVID-19 pandemic further complicated these efforts, limiting face-to-face data collection and necessitating a shift toward online surveys. This change compromised the depth and reliability of data in 2020; for example, the 2020 National Survey on Drug Use and Health report only includes data from the first quarter and used web-based methods for the fourth quarter [1]. In addition, the transition from *The Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* to *The Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* during this period introduced challenges in comparing the new data with those from previous years due to methodological changes.

The existing studies were limited to fewer drug types and demographics of smaller cohorts that mainly focused on the peak pandemic period and did not account for trends before and after the pandemic. Thus, in our research, we have aimed to use large-scale social media data to examine a broader spectrum of drug types, aiming to provide a more comprehensive understanding of drug use trends during the COVID-19 pandemic.

Previous research on social media often used keyword-based and traditional machine learning approaches to analyze drug-related content. Notably, studies [52,53] have identified potential SU incidents using keyword-based methods, that is, by detecting specific drug names such as Adderall, oxycodone, quetiapine, metformin, cocaine, marijuana, weed, methamphetamine, tranquilizer, etc. However, these keyword-based methods are limited, as they often fail to discern the context in which terms are used, resulting in significant ambiguities [54]. Users frequently use slang and metaphorical language that these models cannot adequately interpret. In addition, other studies [53,55-57] have used traditional machine learning classifiers such as naive Bayes, support vector machines, and decision trees. While enhancements such as word2vec for word embedding have been applied, these methods typically struggle with the subtleties of language used in social media. Despite some advancements in sequence-based models, such as long short-term memory or convolutional neural networks [54,58], these approaches still fall short of fully understanding contextual meanings, a challenge effectively addressed by the attention mechanism [59]. Thus, in our research, we have adopted the Robustly Optimized Bidirectional Encoder Representations from Transformers Pretraining Approach (RoBERTa) [60] model, which leverages an advanced attention mechanism to overcome these limitations. This implementation represents a novel application in the analysis of large-scale social media data for drug use studies. Despite the challenges posed by limited annotated data availability, we have incorporated an iterative learning process inspired by human-in-the-loop (HITL) [61] and active learning techniques [62] to further enhance the accuracy of our model. This approach not only refines the model with each iteration but also focuses on learning from the most informative data points, streamlining the data annotation process.

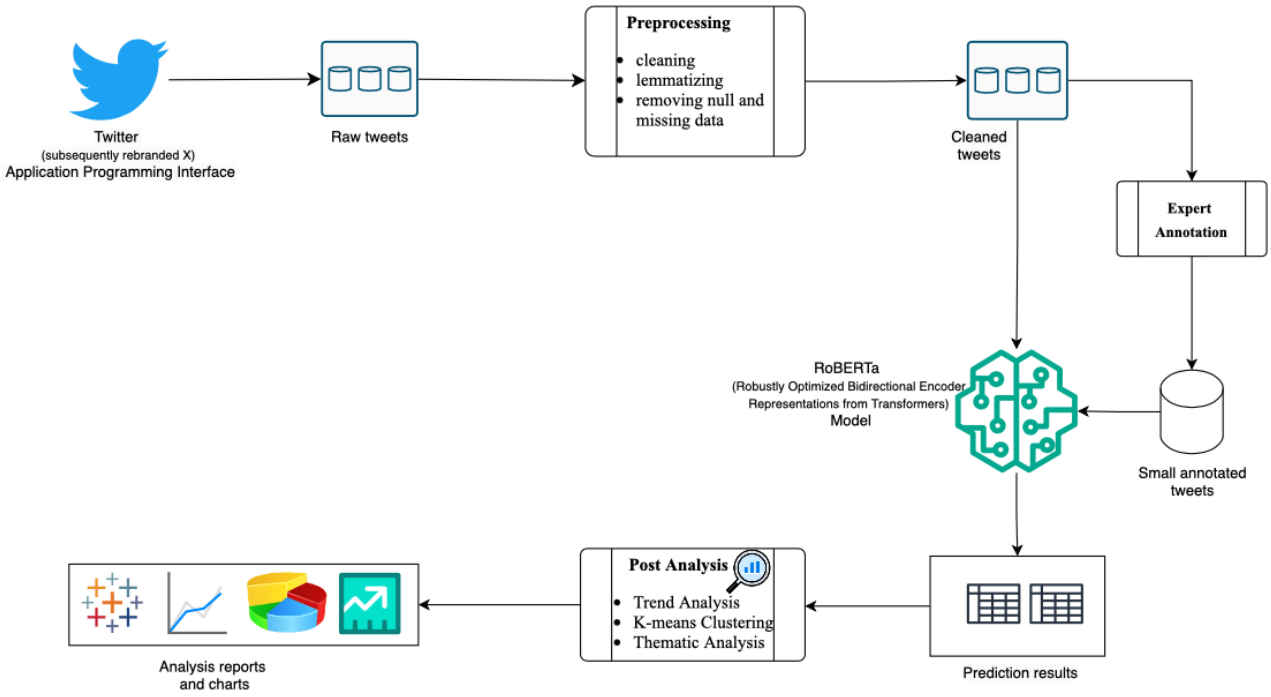
In summary, in this research, we sought to study a large amount of data from Twitter spanning a 3-year period, including the prepandemic (2019) and postpandemic (2020) periods as baseline and consequence periods, to identify the patterns of drug use using a deep learning model (RoBERTa) and various other statistical methods (trend analysis, k-means clustering, topic analysis, and thematic analysis), which are explained in the Methods section in detail. In addition to this, we also aim to analyze different types of drugs and themes in the SU discourse. Specifically, we aim to answer the research questions presented in Textbox 1.

Textbox 1. Research questions.

1. How did the discourse on substance use (SU) evolve on Twitter (subsequently rebranded X) from 2019 to 2021, and what variations existed in the distribution of different substances during this time?
2. Following the announcement of the pandemic, what were the primary substance types that garnered significant discussion, and what were the themes of these dialogues?
3. How did the prevalence of the studied theme influence various types of substances during the underlying study period?
4. How did the identified themes correlate with the substance types?
5. What primary discussion topics arise from k-means analysis, specifically during the study period?
6. To what degree does the classifier's effectiveness in pinpointing SU-related tweets during the pandemic align with or differ from GPT-3?
7. How has the overall system contributed to the real-time tracking of SU, as evidenced by the research?

Contributions

The study's main contributions are as follows:



1. A large-scale SU behavior tweet collection system with expert-annotated tweets for supervised learning
2. A customized pretrained language model based on social media data (Twitter) and an iterative supervised deep learning algorithm for detecting SU posts
3. Insightful statistical analysis of the identified SU posts
4. A real-time search engine–based application for monitoring SU in temporal and spatial dimensions

Methods

Figure 1 shows the overall methodology used in the research. All the steps mentioned in the flow diagram are described subsequently.

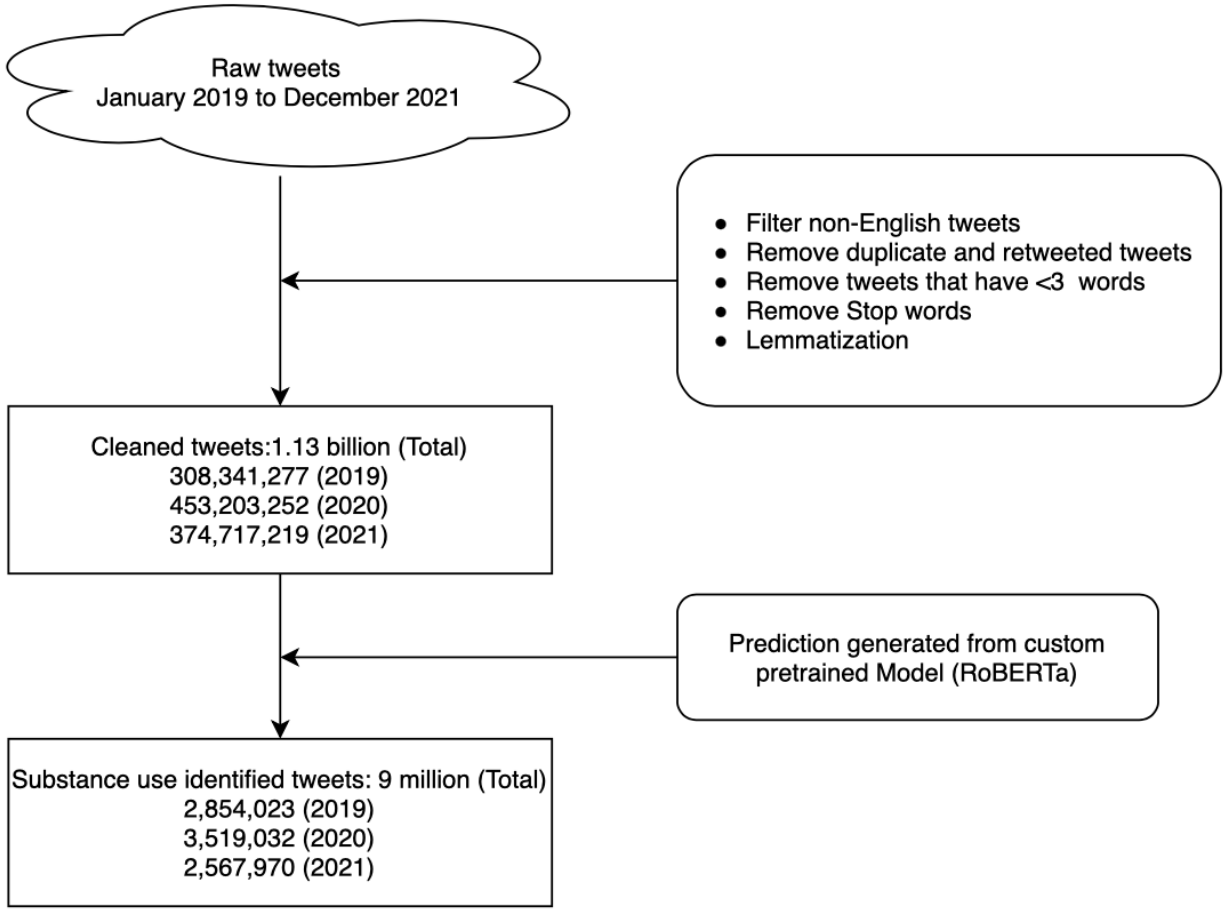
Data Collection

For this research, historical Twitter data were obtained from the Internet Archive [63], a digital library committed to providing free access to a wide array of digital information, including web pages, texts, audio, and videos. This nonprofit organization archives digital content to preserve it and make it accessible for future research. Among its many resources, the Internet Archive includes collections of Twitter data, which consist of tweets captured until July 2023. In our research, we downloaded the raw tweet data covering the period from January 2019 to December 2021. Initially, the data downloaded from this source were in compressed JSON formats, consisting of a large set of files for each day. A pipeline script was developed to extract these files and consolidate them into single-day JSON files. During the extraction process, we retrieved only the time stamp and the actual text of the posts for our analysis. It is important to note that the raw tweets for some days were missing in the data source, specifically in February 2020, January 2021, and April 2021. This absence resulted in skewed time series plots in these months, as discussed in the Results section.



Data Preprocessing

The preprocessing of raw tweets was a crucial initial step to ensure the quality and relevance of the data for further analysis. To efficiently preprocess the large-size files, we divided each daily JSON file into smaller chunks, loaded them in memory, processed each chunk individually, and then merged them back into a single file. The preprocessing steps are described subsequently.

Initially, we filtered out all non-US tweets and duplicate or retweeted tweets to focus our research on English-language tweet posts and reduce redundancy, respectively. Then, we cleaned the text data by removing punctuation and stop words using the Nature Language ToolKit (*NLTK*) package and converted all characters to lowercase to maintain uniformity and prevent discrepancies caused by case sensitivity. Subsequently, we also replaced all the usernames, URLs, and hashtags in the post with the keywords “USER,” “HTTPURL,” and “HASHTAG” to hide the users’ identity and ease semantic understanding. Then, we performed lemmatization using the *NLTK* package to reduce words to their base form (eg, “drinking” to “drink”) to standardize text and improve consistency. Finally, we removed tweets containing <3 words, as these were deemed too brief to provide substantive insights. This comprehensive preprocessing approach resulted in a refined dataset of 1.13 billion cleaned tweets (n=308,341,277, 26.84% in 2019; n=453,203,252, 40.05% in 2020; and n=374,717,219, 33.11% in 2021) poised for further analysis, as depicted in Figure 2.

Feature Extraction and Data Annotation

Overview

Three specialized domain experts in mental health, SU, and public health performed the data annotation process. The main purpose of annotating data was to serve as a seeding dataset to train our deep learning RoBERTa model. Furthermore, as we intended to identify the SU posts in natural language social media data (where users might not clearly mention the drugs but still talk about SU), our goal was to collect and annotate data that were based on context rather than just keyword-based posts. Thus, we first outlined the context of SU based on 3 main criteria, namely *Types of Substance*, *Uses of Substances*, and *Intent to Use a Substance*.

Types of Substance

Substance type posts usually indicated either direct mention of drug names (that could be slang or street names) or described consuming them with or without actual drug names by specifying slang. The detailed list of such drug names, along with the street names and slang, are outlined in Table S1 in Multimedia Appendix 1. For instance, the tweet, “Man, just chill and smoke weed” had a direct mention of the substance “weed” with a clear meaning of SU. Likewise, “Just smoked a joint after work” had an indication of cannabis use hinted by the keyword *joint* even though the post had not specified the actual drug name. We acknowledge that Table S1 in Multimedia Appendix 1 contains a wide range of keywords or slang that might not have a direct association with SU. Hence, careful consideration has been made while annotating posts that contain slang but do not refer to SU. One counterexample of this would be “His joints and bones ache and his muscles seize up.” Here, the post does not have any context with SU even though it contains the keyword *joint*. Hence, it is labeled as a non-SU post.

Uses of Substances

SU posts were identified as posts that described the context of the use of substances, including experiences, effects, or consequences of consumption. The description usually covered personal anecdotes, stories, testimonials, promotions, advice, or recommendations about consumption, and information on obtaining substances. Examples included posts such as, “Feeling relaxed and happy after taking my meds—Xanax does wonders” and “Anyone needs advice on chilling out? I swear by CBD gummies.” In both examples, the post specified the consequence of consuming substances without mentioning the actual names of the substances.

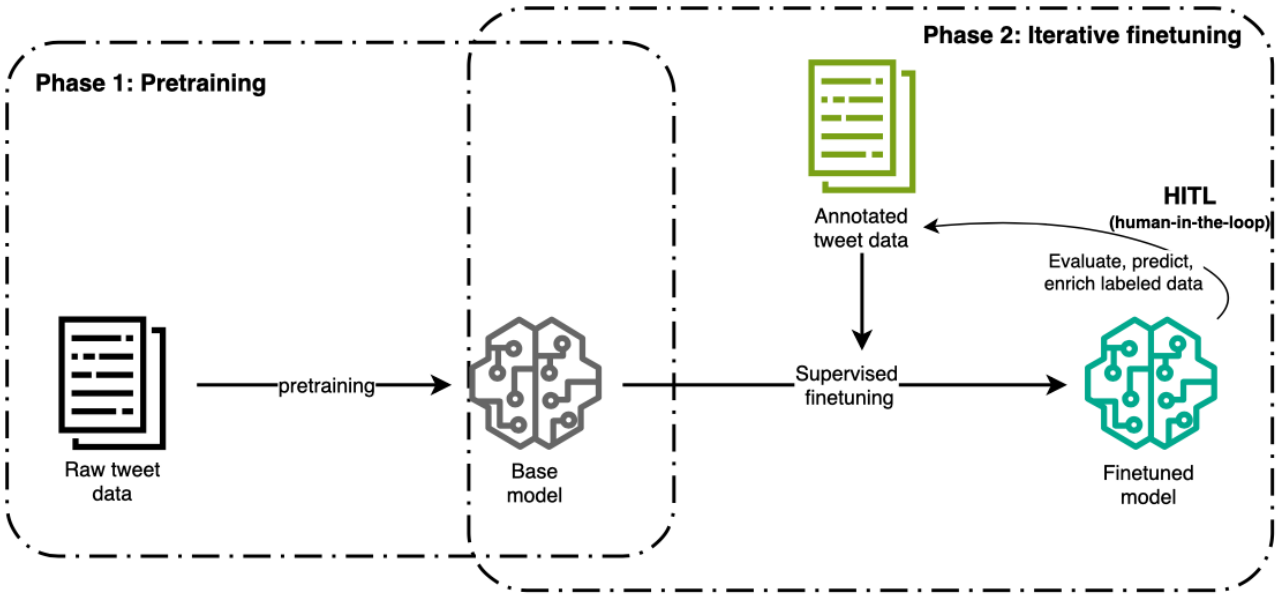
Intent to Use a Substance

Substance intent posts were posts that exhibited actions or behaviors suggesting preparation for specific plans to engage in or a desire for SU and were classified as indicative of SU. Examples included “Planning to get some crystal tonight, can’t

XSL•FO
RenderX

wait" and "Thinking about getting high this weekend to unwind." These examples indicated the actual plan of consuming the substance without clearly mentioning the substance type.

Once the context of SU had been outlined, we proceeded with collecting tweets to annotate. We collected a subset of raw tweets (ie, without cleaning or preprocessing) from January 2020 through April 2020 and asked each domain expert to independently review and annotate a batch of collected tweets under the previously defined criteria. The annotation for each single post was confirmed only if at least 2 annotators voted the same. Upon discrepancies, the annotators further convened to discuss and repeated the process until a consensus was met. This iterative process ensured high reliability and validity in identifying instances of SU. The final annotation resulted in a corpus of 4011 posts. Sample examples of annotated SU and non-SU tweets are included in Table S2 in Multimedia Appendix 1. This thorough annotation process aided in creating a reliable training dataset for fine-tuning our SU classifier.



RoBERTa Model for Tweet Classification

Overview

In our research, we used the RoBERTa model [60], an advanced iteration of the Bidirectional Encoder Representations from Transformers (BERT) model [64], which itself marked a significant breakthrough in natural language processing. Developed by Google, BERT harnesses the power of the transformer architecture [59], notable for its innovative attention mechanism. This mechanism generates word embedding that captures deep contextual meanings within the text by enabling the model to consider each word in the context of all other words in a sentence rather than in isolation. The BERT model is structured to undergo 2 training phases, a pretraining phase and a fine-tuning phase, which is advantageous when adapting to specific tasks with limited available data. During the pretraining phase, the model learns general language patterns from a large text corpus through the masked language model (MLM) and next sentence prediction (NSP). MLM encourages the model to predict missing words based only on their context, enhancing its understanding of language nuances. NSP trains the model to understand the relationships between consecutive sentences, which is vital for tasks that require an appreciation of text flow. The fine-tuning phase then specifically adapts the pretrained model to nuanced tasks using smaller, specialized datasets, ensuring that the model maintains robust performance by refining the comprehensive linguistic capabilities developed during pretraining. Our objective could have been achieved by the BERT model; however, the elimination of the NSP task in the RoBERTa model simplifies the architecture, thereby making it the best fit for our use case. Unlike in BERT, RoBERTa only focuses on capturing contextual meaning (on the MLM task) rather than sentence relationships (on the NSP task), which is more relevant to tweet dataset context because tweet data are usually short sentences that do not require sentence relationship information. This modification makes RoBERTa more robust without compromising all the key features of BERT.

In the subsequent subsections, we explain the pretraining and fine-tuning phases carried out in our research, as depicted in Figure 3.

Figure 3. Illustration of training 2 phases Robustly Optimized Bidirectional Encoder Representations from Transformers Pretraining Approach model for substance use tweet classification. HITL: human-in-the-loop.

Pretraining From Scratch

The specific linguistic challenges of our Twitter dataset necessitated a training-from-scratch approach to avoid biases from generic training datasets. In our method, we primarily adopted this customized approach to learn the language understanding of social media data from 33 million raw Tweet posts as shown in the phase 1 of Figure 3.

Initially, we performed tokenization using ByteLevelBPETokenizer. Essentially, this sub–word-level tokenizer broke down words into subword units, allowing it to handle out-of-vocabulary words and rare words more effectively than word-level tokenizers, thus enabling more coverages and

XSL•FO
RenderX

generalizations in domains with specialized terminology such as ours. We used 8192 vocab_size and min_frequency 2 as hyperparameters, along with [“<s>”, “<pad>”, “</s>,” “<unk>”, “mask>”] special tokens to indicate the start of the sentence token, padded token, end of the sentence token, unknown token, and masked token, respectively. Additional parameters are provided in Tables S3 and S4 in Multimedia Appendix 1.

After tokenization, we split the original dataset into 2 splits: as the training set (n=29.7 million, 90%), the testing set and (n=3.3 million, 10%). Then, we started training with the MLM objective, where a fraction of tokens (n=4.45 million, 0.15%) in each input sequence were masked, and the model learned to predict them based on contextual information. Training proceeded iteratively using stochastic gradient descent, with hyperparameters tuned based on validation performance. The model achieved a perplexity of 3.84 on the test data, which served as a baseline evaluation of the model. We ensured our language model was efficient by further evaluation after the fine-tuning step.

Iterative Fine-Tuning

Overview

After our model successfully deciphered language understanding in social media data, our next objective was to leverage this knowledge to distinguish posts related to SU. We achieved this by incorporating an additional binary classification layer into the existing model and retraining it with a newly labeled dataset, as depicted in the phase 2 of Figure 3. As with the unsupervised pretraining, we divided the dataset into training, validation, and test splits. We then retrained (fine-tuned) the newly annotated dataset, adjusting the model’s weights by calculating the error between the predictions and the actual labels using an optimization algorithm.

However, to prevent overfitting due to the limited size of the initially labeled data, we adopted an iterative fine-tuning approach inspired by HITL [61]. HITL is a collaborative technique that integrates human input at various stages of model development, such as training, testing, feedback, and decision-making [61]. In our case, we used HITL in only the training phase. We used human reviewers to only assess the model’s prediction results, which were then used to further train the model in successive rounds. Specifically, the process began with training the model on a seed-labeled dataset, followed by generating predictions for unseen data. Furthermore, these predictions were reviewed by human experts to refine and enrich the annotated dataset, which was used for subsequent training. This iterative cycle of training, prediction, and human review continuously improved the model’s performance by enhancing the quality of the training data.

The overall steps in our fine-tuning phase are detailed in the algorithm mentioned subsequently.

Step 1: Data Split

Before training the model, we split our 4011 annotated dataset into 3 sets: the training set (n=3208, 80%), the testing set (n=402, 10%), and the validation set (n=401, 10%).

Step 2: Initial Fine-Tuning and Cross-Validation

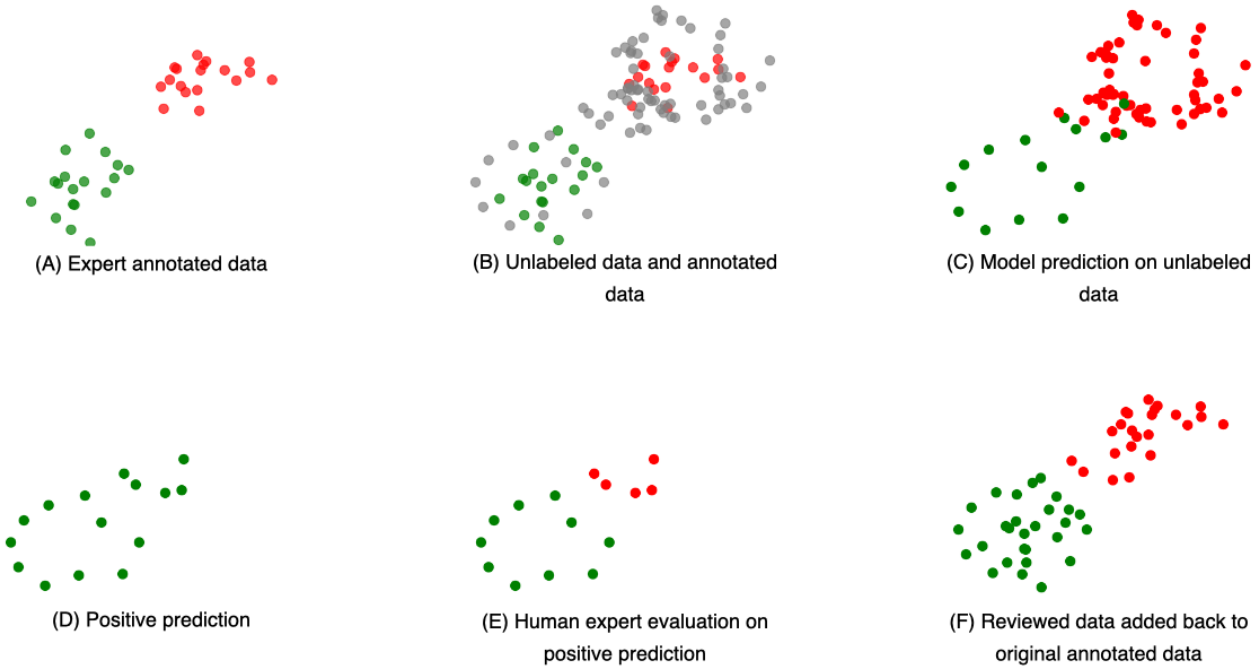
The initial parameters from the pretrained model were initialized. Then, the model was fine-tuned with the training dataset for 32 epochs on a batch size of 16 and a learning rate of 2e-5. A dropout layer was added to prevent overfitting, and the model was evaluated using a separate held-out dataset to ensure unbiased parameter tuning.

Step 3: HITL for Generating a New Labeled Dataset

Overview

Our ultimate objective at this step was to leverage human experts to pinpoint crucial data points that could enrich the annotated dataset and refine the model’s accuracy. Human experts reviewed the model’s predictions on unseen data and then identified and corrected errors. This feedback (corrected data) was then used to train the model in the next iteration.

Step 3.1: Prediction of Unseen Data



We used the refined model from step 2 to generate predictions of new, unseen data.

Step 3.2: Expert Review on Positive Predictions

Due to the severe imbalance in the dataset (0.05 positive, 0.95 negative), as shown in Figure 4, we focused exclusively on reviewing positive predictions. Concentrating on positives and making corrections to false negatives allowed us to directly improve the model’s sensitivity and precision. This approach ensured that the model better recognized the critical but infrequent true positive cases, thus enhancing overall accuracy and robustness.

XSL•FO
RenderX

Figure 4. Illustration of datasets in different stages used in the iterative fine-tuning phase. SU: substance use.

Step 3.3: Annotation

We leveraged our expert knowledge to annotate misclassified positives (false negatives) as negatives and correctly identified positives (true positives) as positives.

Step 3.4: Bias Reduction

To address potential bias by specifically focusing on positive predictions, we selectively reviewed a subset of complex positive predictions, which were likely to be misclassified as negatives. For example, posts using metaphoric language or slang, such as “riding the white horse,” to indicate heroin use, required nuanced interpretation beyond simple keywords. By targeting these complex positives, we aimed to reduce the bias of not reviewing negative predictions. This careful attention to positive predictions ensured that we minimized the risk of failing to identify true instances of SU hidden within the data labeled as negative.

Step 3.5: Outcome

The final subset of true positives from Bias Reduction and misclassified positives from Annotation were considered as newly annotated data. In each iteration, we made sure the outcome contained 100 positive and 100 negative posts.

Step 4: Expansion of the Original Annotated Dataset

The outcomes from step 3 were added to the original annotated dataset.

Step 5: Evaluation and Iteration (Repeating Steps 1, 2, 3, and 4)

The fine-tuning was carried out for 20 iterations, expanding the annotated dataset in each iteration up to 6400 entries. At each round, we evaluated the model’s accuracy on the test set and repeated the process until we achieved the desired accuracy of 80%.

In addition to achieving 80% accuracy, the model demonstrated strong performance across other metrics, with a recall of 79%, a precision of 85%, and an F_1-score of 81%. These scores indicated that the classifier effectively identified most SU instances while maintaining a low rate of false positives, ensuring balanced overall performance.

Substance Definitions and Their Types

A substance encompasses any psychoactive compound that can be legal, illegal, or medically prescribed, with potential impacts on health and society, including the risk of addiction. In our study, we classified substances into 10 primary categories based on their pharmacological and behavioral effects, following the categorization provided by the NIDA [65] and the Drug Enforcement Administration [66].

These categories are presented in Textbox 2.

The specifics for each substance category, including associated keywords, are detailed in Table S1 in Multimedia Appendix 1.

XSL•FO
RenderX

Textbox 2. Classification of substances into 10 primary categories based on their pharmacological and behavioral effects.

1. Tobacco: includes cigarettes, vapor cigarettes, cigars, chewing tobacco, and snuff
2. Alcohol: covers all forms of beer, wine, and distilled spirits
3. Cannabinoids: encompasses marijuana, hashish, hash oil, and edibles containing cannabinoids
4. Opioids: includes drugs such as heroin, methadone, buprenorphine, oxycodone, Vicodin, and Lortab
5. Stimulants: includes cocaine, amphetamines, methamphetamine, methylphenidate (eg, Ritalin), and atomoxetine (eg, Strattera)
6. Club drugs: includes 3,4 methylenedioxymethamphetamine (MDMA) or ecstasy and gamma hydroxybutyrate (GHB)
7. Hallucinogens: lysergic acid diethylamide (LSD), psilocybin, mescaline, and dimethyltryptamine
8. Dissociative drugs: ketamine, phenyl cyclohexyl piperidine (PCP), and dextromethorphan
9. Prescription medications: a broad category that includes antibiotics, analgesics, statins, antidepressants, antihypertensives, hormonal contraceptives, and anticoagulants
10. Other compounds: features synthetic cannabinoids (eg, K2 or spice), anabolic steroids, inhalants, and synthetic cathinone (eg, mephedrone and methylenedioxypyrovalerone [MDPV])

Baseline Themes

The relationship between COVID-19 and SU patterns has garnered significant attention, with the COVID-19 pandemic serving as a critical case study. Previous research [4-6,14,15,31,36,37,67-70] highlighted various thematic areas that significantly influence SU, including stress and concerns related to COVID-19, economic instability, social dynamics, mental health issues, and disruptions in drug supply and health care services. Our study encompassed 6 key themes—COVID-19, economic factors, social influences, mental health, supply chain disruptions, and health care disruptions, as presented in Table 1. A short description of each theme and the impacted individuals (target population), along with study references, are listed in Table 1. To identify the themes in our dataset, we performed latent Dirichlet allocation (LDA) topic analysis to extract the tokens associated with each theme. Then, we refined the list of these tokens with the help of our experts. The complete list of tokens for each theme is detailed in Table S5 in Multimedia Appendix 1.

Table 1. Six major themes that impacted substance use during the global COVID-19 pandemic.

Themes	Description	Target	Studies
COVID-19	Worry or fear related to the virus and lockdown	All people with or without SUD[a]	[4,5,31,36,67]
Economic	Financial instability, job stress, housing, and food insecurity	All people with or without SUD	[5,68-70]
Social	Stress caused by the COVID-19 lockdown, social distancing policies, and change in daily routine	All people with or without SUD	[5,36,37,68,70]
Mental health	Anxiety and depression before COVID-19	Especially people with SUD	[4-6,36,37,68,70]
Supply disruption	Drug market disruptions	Especially people with SUD	[4,13-15]
Medical disruption	Decreased access to substance use treatment, harm reduction, and emergency services	Especially people with SUD	[4-6,68,70]

[a]SUD: substance use disorder.

Trend Analysis

Overview

Trend analysis is the most common technique for identifying patterns over time. In our study, trend analysis involved tracking and analyzing changes in types, discussion patterns, and themes associated with identified SU posts. We mainly used substance-type trend analysis, theme trend analysis, and k-means clustering analysis. At first, we identified the substance type, themes, and discussion pattern for each post by the keyword analysis based on Tables S1 and S5 in Multimedia Appendix 1, LDA topic analysis, and k-means clustering, respectively. Then, the subsequent trend analysis was performed.

Substance-Type Trend Analysis

To identify the substance type in the post, we first formulated a list of street names and slang words associated with the substance and labeled it with corresponding types, such as labeling post 1 for tobacco type if it contained any terms related to tobacco substance. The samples of posts, along with the identified substance type, are presented in Table S6 in Multimedia Appendix 1. Following identification, we aggregated the posts according to type and visualized the time series and histogram plot to identify and compare the growing trends in each substance type.

Theme Trend Analysis via LDA Topic Modeling

Theme trend analysis is a methodological approach that combines elements of theme analysis and trend analysis to

XSL•FO
RenderX

understand how specific themes or topics evolve within a dataset. In order to understand key topics of discussion, we used LDA topic modeling [71], a powerful unsupervised machine learning technique, to discover abstract topics within a collection of documents. We used this to answer question 2 (Textbox 1) specifically, where we generated the top 10 topics with the top 10 keywords and categorized the topics based on the identified baseline themes.

k-Means Clustering Analysis

k-means clustering is an unsupervised machine learning algorithm used to partition a dataset into k distinct, nonoverlapping clusters based on the similarity of data points by minimizing the variance within each cluster and maximizing the variance between different clusters [72]. The algorithm iteratively assigns data points to one of the k clusters based on the closest mean (centroid) of the cluster until the positions of the centroids stabilize. In our case, we used the scikit-learn library to perform the k-means clustering, where we used the term frequency-inverse document frequency scheme to create vectorization and considered the elbow method to identify the value of k for performing the clustering.

Thematic Analysis

Thematic analysis is used in qualitative research to analyze and interpret theme patterns within qualitative data. In our study, we used heat map analysis and factor analysis [73-75] to visually explore the relationship between identified themes and types of substances and to identify latent factors (patterns) from the observed themes, respectively.

Integration in Real-Time Application

We also integrated the trained model into a real-time application to monitor SU using the Elastic Logstash Kibana stack. We set up a search engine framework—using search database [76] and logstash [77]. Elasticsearch is an open-source, distributed, RESTful, JSON-based search engine originally based on Lucene (Solr) search that stores the document or the JSON object in an inverted index structure and allows the fastest full-text search. Logstash is a server-side data processing pipeline that usually sources or sinks data to and from multiple sources. In our work, we leveraged this pipeline to ingest the document and tweets from MongoDB [78], transformed the document by adding a custom call to generate a prediction result from the trained model, and finally wrote the document in Elasticsearch. The final document was a JSON comprising a tweet body with an additional prediction field from the trained model. Meanwhile, the Elastic Logstash Kibana stack had a built-in visualization tool to generate different trending charts based on real-time data during the development phase. We developed a full-fledged application in AngularJS and ReactJS frameworks for the client's real-time purposes. The snapshots demonstrating the chart showing the temporal and spatial analysis based on different filters are presented in the *Results* section.

Comparison With GPT-3

The advent of large language models, particularly GPT-3 [79], seemed to have raised questions regarding the efficiency and validity of custom models such as ours. Thus, we compared the reliability of our RoBERTa model and GPT-3 model in identifying SU posts. For this, we randomly sampled 3150 positive predictions from our customized model and queried GPT-3. Essentially, we designed a GPT-3 prompt, "Is this tweet <a real tweet post> related to substance use: Yes or No?" and queried for all sampled posts. Then, the predictions made by our model and GPT-3 were evaluated by our human experts.

Ethical Considerations

To ensure the privacy and confidentiality of individuals whose data were analyzed, all study data underwent a rigorous deidentification process before analysis. The data for this study were sourced from publicly available platforms [63] containing no personally identifiable information. In addition, all the sample posts were preprocessed, removing user IDs, emails, URLs, numbers, stop words, and lemmatizing, making the resulting tokens impossible to identify users' information. Thus, there was no personal information, including author names or any other private information, in the dataset. By addressing these ethical considerations, we conducted insightful research on SU patterns using social media content. In addition to this, our research was supported by the Substance Abuse and Mental Health Services Administration Strategic Prevention Framework-19 (grant 6H79SP081502), which was approved by the institutional review board at Kent State University (IRB20-182).

Results

Overview

Our primary objective was to comprehensively analyze the trends and patterns of SU over 3 years. To identify SU posts, we developed a self-trained deep learning model that achieved a precision rate of approximately 80%. This model was then used to detect SU tweets. The yearly breakdown of identified posts revealed 2,854,023 posts in 2019; 3,519,032 in 2020; and 2,567,970 in 2021. The identified data underwent various quantitative and qualitative analyses, such as trend analysis, k-means cluster analysis, topic and theme analysis, and factor analysis. To enhance the robustness of our findings, we validated our results by comparing them with those obtained from a GPT-3 model [79]. In the final section of our results, we present the outcomes of our integrated real-time application, showcasing the practical implications of our analyses.

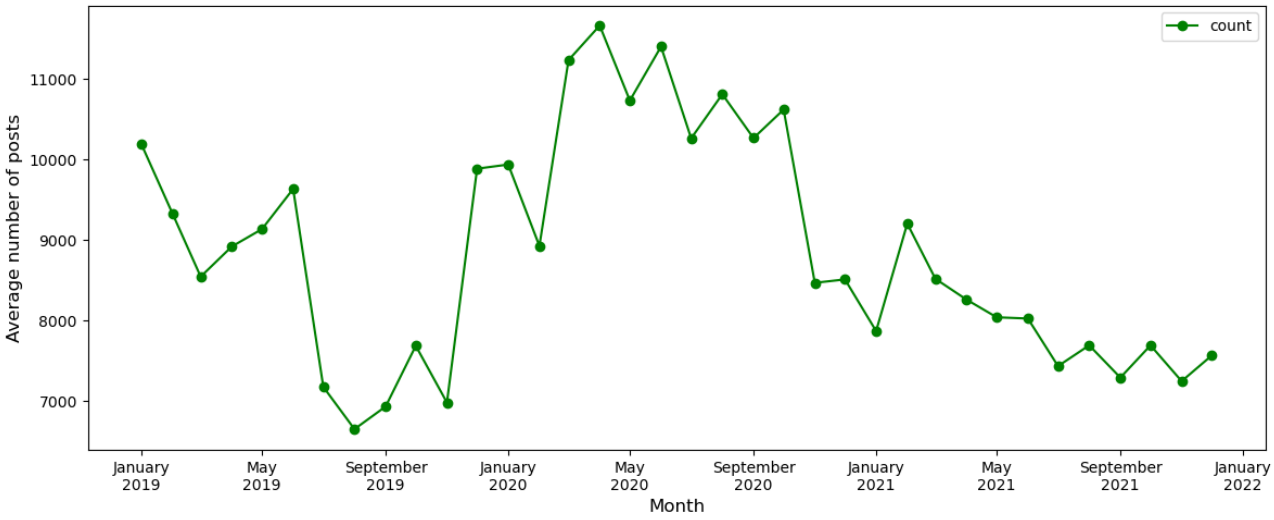
Trend Analysis (Question 1: How Did the Discourse on SU Evolve on Twitter From 2019 to 2021, and What Variations Existed in the Distribution of Different Substances During This Time?)

We began our research by conducting a time series analysis to understand the SU trend in the following 3 periods: the prepandemic period, the pandemic period, and the postpandemic period. We aggregated identified SU posts monthly to plot in the chart. Figure 5 shows the average number of SU posts for the entire study period. The proportional representation of the same chart can be found in Figure S1 in Multimedia Appendix 1. While the trend in average number seems substantially high in 2020 in comparison to pre- and postpandemic periods (Figure 5), the proportion of posts for the same data is observed to decline from 2019 to 2021.

XSL•FO
RenderX

In addition, we also plotted a time series for 10 different substance categories to learn the trend of substances by categories. Thus, at first, we categorized each of the posts by applying a keyword-based method by referring to standard keywords from the NIDA [65], as outlined in Table S1 in Multimedia Appendix 1. For instance, we marked the post as alcohol if it contained any keywords associated with it and so forth. After the classification, we plotted the distribution for each substance type to visually understand the trend of each substance type in the study period, as shown in Figure 6.

Figure 5. Substance use distribution from 2019 to 2021.



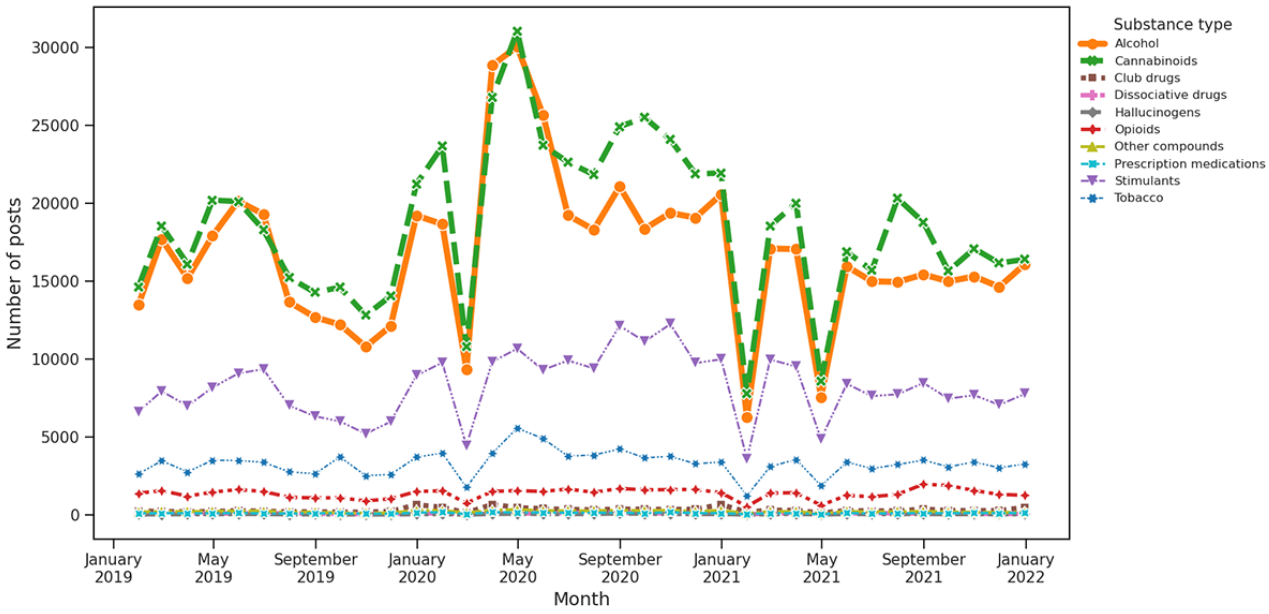


Figure 6. Substance type distribution from 2019 to 2021.

LDA Topic Analysis (Question 2: Following the Announcement of the Pandemic, What Were the Primary Substance Types That Garnered Significant Discussion, and What Were the Themes of These Dialogues?)

Drug Distribution 7 Days Before and After the Pandemic Declaration Day

Following the announcement of the pandemic on March 15, 2020, by Donald Trump, our result evidenced a significant 21% surge in the mentions of SU in tweets in just 3 days. Thus, understanding the change in pattern during that period was essential. We selected data from 7 days before and after March 15 to learn the impact of the pandemic declaration date on the trends. Thus, we aggregated the post count by each substance type 7 days before and after March 15, as shown in Table 2. The time series plot for the same period is also provided in Figure S3 in Multimedia Appendix 1.

XSL•FO
RenderX

Table 2. Substance type distribution 7 days before and after the pandemic declaration day.

Period and substance type	Proportion of posts, n (%)
Seven days before March 15, 2020 (n=54,671)	
Tobacco	2165 (3.96)
Alcohol	15,620 (28.57)
Cannabinoids	23,837 (43.6)
Opioids	1345 (2.46)
Stimulants	10,241 (18.74)
Club drugs	1000 (1.83)
Dissociative drugs	98 (0.18)
Hallucinogens	87 (0.16)
Other compounds	470 (0.86)
Prescription medications	98 (0.18)
Seven days after March 15, 2020 (n=56,773)	
Tobacco	1936 (3.41)
Alcohol	19,661 (34.63)
Cannabinoids	21,341 (37.59)
Opioids	835 (1.47)
Stimulants	7914 (13.94)
Club drugs	613 (1.08)
Dissociative drugs	131 (0.23)
Hallucinogens	57 (0.1)
Other compounds	199 (0.35)
Prescription medications	2606 (4.59)

LDA Topic Analysis

Furthermore, to comprehend the nuances of keywords and topics discussed following the declaration of the pandemic, we conducted an LDA topic analysis on these periods, 7 days before and after the official declaration. As shown in Tables 3 and 4, we highlighted the 10 main topics along with the distribution of the posts across each topic. Also, each topic consisted of the topmost terms that were extracted, excluding stop words.

Table 3. Top 10 terms of 10 latent Dirichlet allocation topics (7 days before the pandemic declaration day).

Topic	Top 10 terms	Distribution (n=54,671), n (%)
0	wine, buy, smoking, glass, everyone, water, red, drink, taste, beer	2733 (5)
1	alcohol, virus, corona, people, cigarette, leave, amp, covid, roll, hit	2733 (5)
2	beer, know, thing, fuck, try, man, cancel, cold, drink, problem	2733 (5)
3	drunk, bar, get drunk, blunt, pain, hold, kill, tonight, sick, coronavirus	2733 (5)
4	liquor, high, store, week, without, bitch, right, keep, always, low	2733 (5)
5	use, coke, would, call, drink, put, lmao, shot, really, enjoy, alcoholic	30,069 (55)
6	smoke, drink, drinking, sleep, drug, coffee, bro, work, fire, outside	2733 (5)
7	crack, night, love, last, stay, damn, smoke, cocaine, end, next	2733 (5)
8	weed, good, need, come, tequila, shit, smoke, drink, day, first	2733 (5)
9	nose, alcohol, bottle, year, please, beer, well, drink, hope, time	2733 (5)

XSL•FO
RenderX

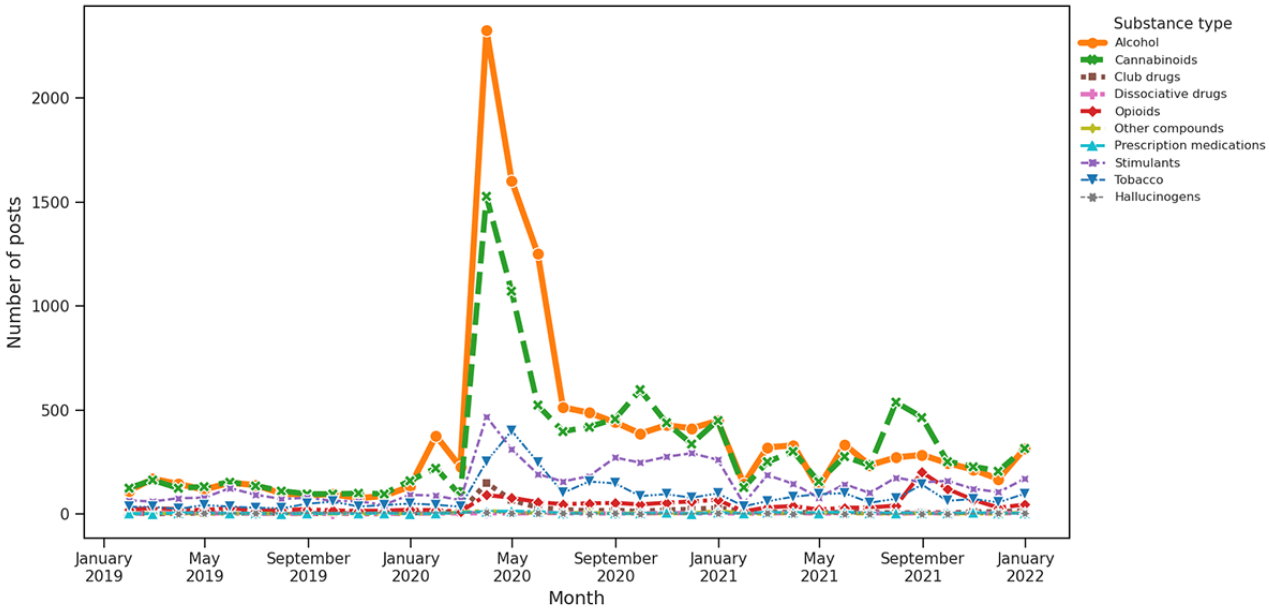

Table 4. Top 10 terms of 10 latent Dirichlet allocation topics (7 days after the pandemic declaration day).

Topic	Top 10 terms	Distribution (n=56,773), n (%)
0	come, smoking, back, man, alcoholic, street, eye, way, chinese, sell	1947 (3.43)
1	drink, drinking, beer, bottle, sleep, tequila, good, drive, tonight, nose	1947 (3.43)
2	liquor, stop, alcohol, store, order, close, bar, help, essential, turn	1947 (3.43)
3	drink, cigarette, smoke, eat, tell, weed, food, hold, even, talk	1947 (3.43)
4	fuck, virus, coke, year, high, shot, corona, covid, people, kill	1947 (3.43)
5	high, last, blunt, night, please, lit, amp, loudlycryingface, thought, die	1947 (3.43)
6	smoke, shit, start, open, feel, find, lmfao, woozyface, asf, miss, fire	1947 (3.43)
7	quarantine, pain, crack, really, use, cocaine, damn, bitch, drug, liquid	39,196 (69.04)
8	wine, would, weed, see, glass, need, someone, lmao, drunk	1947 (3.43)
9	drunk, get, love, friend, house, home, free, eat, wine, stay	1947 (3.43)

Theme Trend Analysis (Question 3: How Did the Prevalence of the Studied Theme Influence Various Types of Substances Used During the Studied Period?)

The theme in any subjective study is either a topic or a related subject name that best describes the group of the data. In our context, we wanted to identify such themes in the SU posts so that we could analyze the pattern and further investigate a correlation with different substances. Thus, we derived 6 major themes, namely COVID-19, economic, social, mental health, supply disruption, and medical disruption, as discussed in the Baseline Themes section in the Methods section. Subsequently, we plotted a time series for each substance type for all themes, as depicted in Figures 7-12. Our research yielded valuable insights through a trend analysis focused on the impact of prevalent themes on SU.

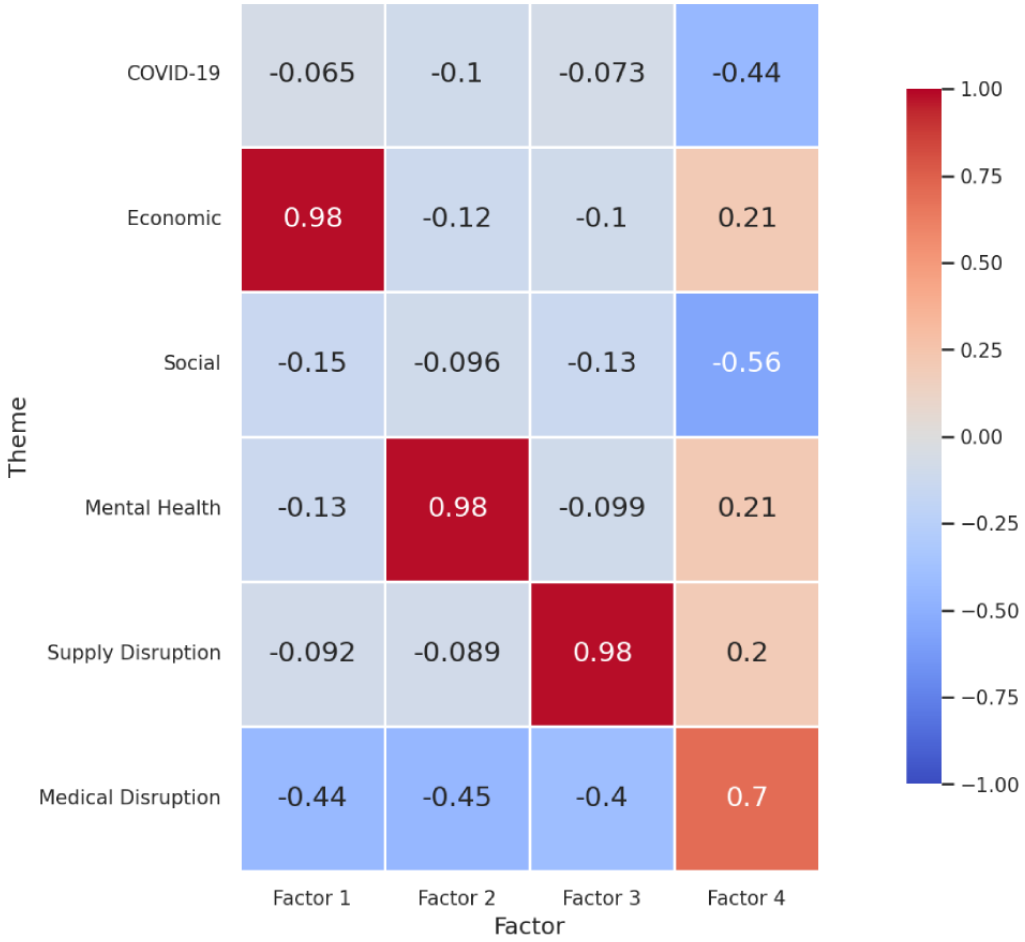
Thematic Analysis (Question 4: How Did the Identified Themes Correlate With the Substance Types?)

We performed heat map analysis and factor analysis to explore the correlation between identified themes.

Heat Map Analysis

In our study, we further used a heat map to visually analyze the relationships between identified themes (COVID-19, economic, social, mental health, supply disruption, and medical disruption) and substance types (alcohol, cannabinoids, club drugs, dissociative drugs, hallucinogens, opioids, other compounds, prescription medications, stimulants, and tobacco). The correlation plot is shown in Figure 13, where themes are represented on the y-axis and substances are represented on the x-axis. Each cell within the grid corresponds to a unique pairing of theme and substance type, with the color intensity indicating the strength of the association between them, and the color scale positioned along the right side of the vertical axis represents the intensity of association between these variables. Here, deeper shades of blue signify stronger associations, while lighter shades, reminiscent of lime, indicate weaker associations.

Figure 13. Heat map between themes and substance types.

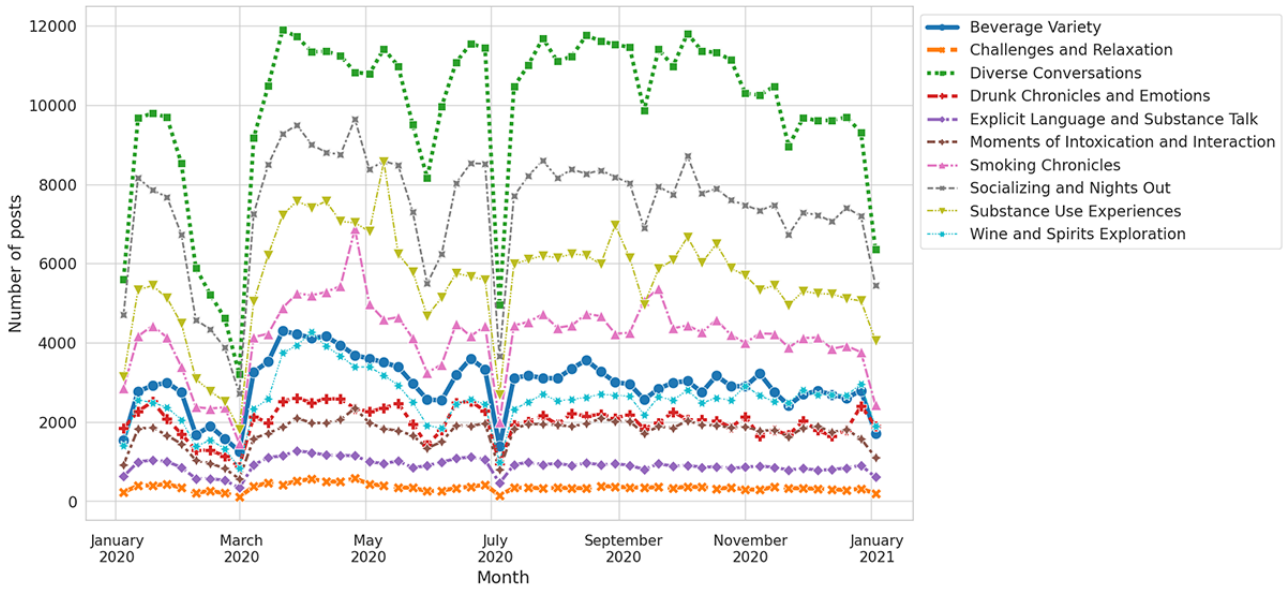


XSL•FO
RenderX

Factor Analysis

We performed factor analysis to examine the variability among the selected themes, aiming to distill these into a smaller set of unobserved, underlying variables known as factors. We determined the optimal number of factors to be 4 based on the Kaiser criterion, a decision further substantiated by the scree plot analysis, which revealed a distinct elbow point (Figure S5 in Multimedia Appendix 1). This analysis was facilitated by the *factor_analyzer* package within the Python application programming interface [45], which calculated the eigenvalues for each factor corresponding to the identified themes. The resultant factor loading heat map is shown in Figure 14. This heat map illustrates the relationships between factors and themes; negative values signify an inverse relationship, while positive values denote a direct relationship. The intensity of the relationship is indicated by values approaching 1 or –1 for strong relationships and values near 0 for weak ones. The heat map uses a color gradient where red shades indicate positive associations and blue shades indicate negative associations, providing a clear visual representation of these relationships.

Figure 14. Factor loading heat map.



k-Means Clustering Analysis (Question 5: What Primary Discussion Topics Arise From k-Means Analysis, Specifically During the Pandemic Year?)

In addition, we also performed k-means clustering on SU posts from 2020 to identify the relevant groups or clusters by leveraging the similar distance algorithm inbuilt in the k-means clustering method [72]. Essentially, we started by applying the elbow method to determine an optimal cluster size, which turned out to be 19 for our data. The elbow diagram is depicted in Figure S4 in Multimedia Appendix 1. Furthermore, we applied k-means clustering to generate 19 clusters. However, due to redundant cluster keywords, we merged the relevant clusters, resulting in 10 main clusters, as shown in Figure 15. The cluster keywords and their respective details are presented in Table S8 and Figure S4 in Multimedia Appendix 1, respectively. Initially, information from each cluster was gathered and categorized into interaction, discussion, feelings, and perceptions. In addition, correlated clusters were amalgamated, such as cluster 0 and 13 labeled as raw conversations—explicit language and substance talk; cluster 1 and 6 as smoking chronicles—weed and cigarettes; cluster 2 and 12 as wine and spirits exploration; cluster 4 and 9 as social highs—moments of intoxication and interaction; cluster 5 and 16 as socializing and nights out—drinks and smokes; cluster 7 and 8 as beverage variety—beers, alcohol, and voting; cluster 10 and 14 as SU experiences—smoking, drugs, and liquor; and cluster 15 and 18 as challenges and relaxation—tiredness, and blunts. Cluster 3, encompassing diverse experiences and activities, was named diverse conversation.

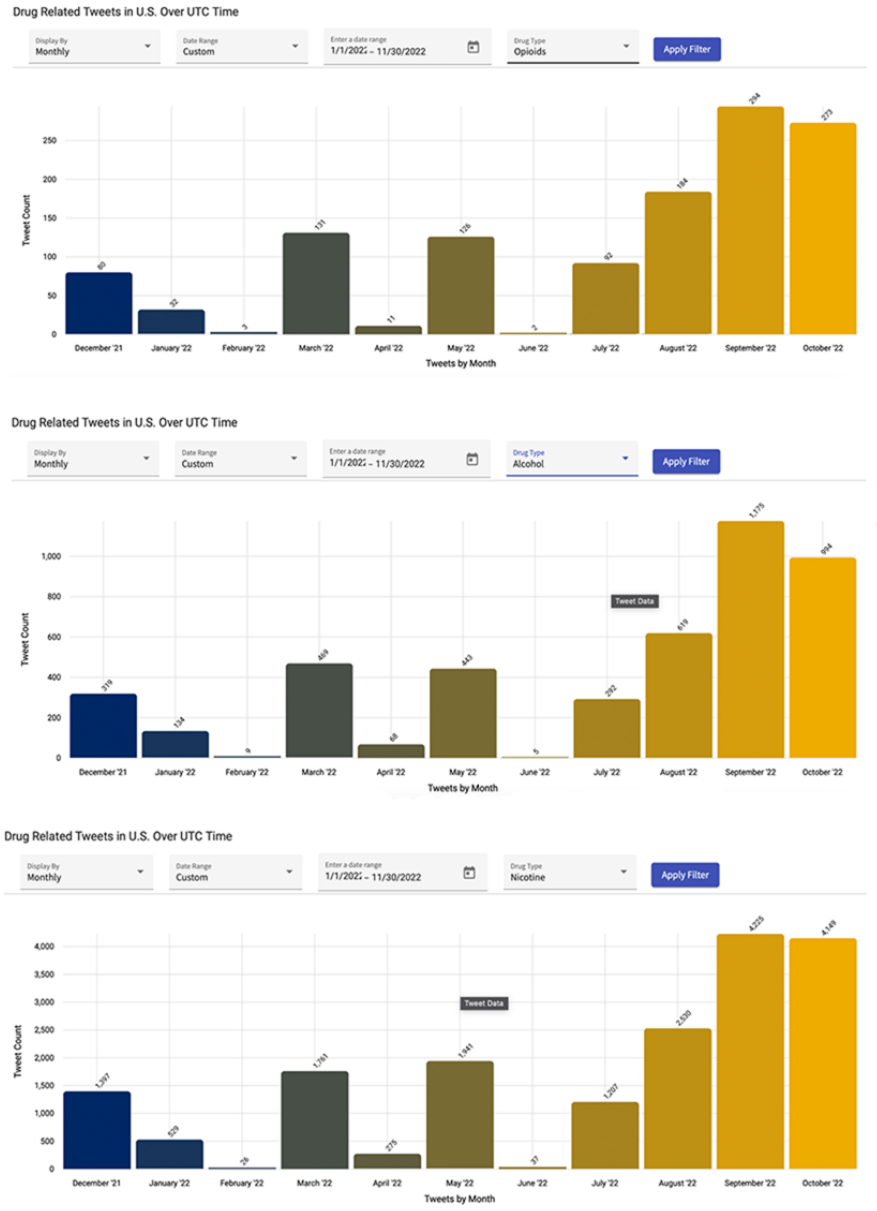
Figure 15. K-means cluster analysis of substance use posts in 2020.

Comparison With GPT-3 (Question 6: To What Degree Does the Classifier's Effectiveness in Pinpointing SU-Related Tweets During the Pandemic Align With or Differ From GPT-3?)



We also compared our results with the GPT-3 model by asking the model to classify tweets using GPT application programming interface [79]. We used a prompt, "Is this tweet '<a real tweet post>' related to substance use: Yes or No?" For this, we randomly sampled 3150 predicted positive results from our customized model and cross verified with the human (experts) and a machine (GPT-3). The human-verified 95.23% (3000/3150) of these predicted positive tweets were accurate, while GPT-3 only verified 53.73% (1693/3150) of the tweets as accurate. From this result, we concluded that generic powerful models such as GPT-3 do not necessarily generate true results when identifying hidden contexts in domain-specific data. This necessitates the need for domain-specific models for accurate results.

Real-Time Application (Question 7: How Has the Overall System Contributed to the Real-Time Tracking of SU, as Evidenced by Research?)

We further deployed our model to provide a real-time service in an application, Northeast Ohio Tri-County Prevention Infrastructure [80], specifically within the social media section designed for Ohio state. Primarily, the aim of the application was to serve as a monitoring and prevention dashboard for the state from static data. However, the real-time nature of social media data gave the application true power to monitor patterns of SU across areas of interest. Figure 16 provides snapshots of the application, illustrating how the stakeholders can dynamically monitor the SU segmented by time and substance type.

Discussion

We used our custom deep learning model and several statistical methods to perform this analysis to get insights into the trends and impacts of COVID-19 related to SU. The subsequent sections elaborate on the results in detail.

Trend Analysis

Time to Event Analysis and Substance Distribution for Question 1

The analysis of time to event reveals a significant increase in SU tweets in 2020, surpassing the counts for 2019 and 2021 by 17.6% and 22.35%, respectively (Figure 5). Notably, March 2020, April 2020, and June 2020 emerged as the focal months for SU discussions, with frequencies 16.55%, 21.18%, and 18.19% higher than other months in 2020. The elevated trend persisted until October 2020, likely coinciding with the availability of vaccines, highlighting a limitation in our study.

The examination of substance discussions over a 3-year time frame revealed a consistent focus on alcohol and cannabinoids, emerging as the predominant topics throughout the study. An intriguing observation during the pandemic period was the discernible surge in discussions surrounding alcohol, cannabinoids, and stimulant drugs, distinguishing them with an upward trend. In contrast, other substances did not exhibit substantial shifts in discourse.

It is crucial to exercise caution when interpreting the data for February 2020, January 2021, and April 2021, as the graph may be skewed due to limited available tweets in the Twitter source during those specific months. Despite this limitation, the broader insights gleaned from the study underscore the enduring prominence of alcohol and cannabinoids in public discourse.

XSL•FO
RenderX

The pandemic period, marked by unprecedented global challenges, evidently influenced a notable increase in discussions surrounding these substances and stimulant drugs, indicative of evolving societal dynamics and coping mechanisms. These findings prompt further exploration into the nuanced factors shaping substance-related discussions, offering valuable insights for public health considerations and policy implications.

Topic Analysis and Substance Distribution for Question 2

In order to observe the impact of the declaration of the global COVID-19 pandemic declaration day on March 15, we analyzed the posts by each substance type 7 days before and after March 15. The aggregated posts in these 2 weeks had distinct changes in each substance type. Notably, discourse in only 2 substance types, alcohol and prescription medication, were observed significantly increasing, while discourse in all other substance types were observed slightly declining. The trend can also be visualized in Figure S3 in Multimedia Appendix 1. The increased trend of alcohol discussion was likely due to the effect of COVID-19, particularly due to closed schools, social isolation, boredom, and various types of mental stress and anxiety, which is also supported by some studies [15,35,36]. A study by Farhoudian et al [15] that conducted a survey in May highlighted the increment in alcohol, prescription medication, and cannabinoids. However, in our study, cannabinoids showed a slight decrement in a 7-day period while it remained significantly discussed during the entire study period.

Moreover, our topic analysis for the same period indicated a shift in substance-related discourse. In general, during the prepandemic period, references to substances were casual in almost all the 10 topics, as depicted in Table 3. Although topic 5 had the highest proportion of keywords (30,069/54,671, 55%), the terms referred to casual keywords, insignificant to any particular substances or behavior. However, topics in the postpandemic period included keywords that concerned quarantine and SU as seen in topics 4 (1947/56,773, 3.43%) and 7 (39,196/56,773, 69.04%) in Table 4. The mention of keywords (such as *nose*, *coronavirus*, and *covid*) during the first period suggested that COVID-19 has been interlinked with few substance discussion; however, there were no negative words indicating stress or bad impact on mental health. By contrast, the topics in the second period included negative keywords (such as *pain*, *die*, *stress*, and *fuck*) along with SU keywords. This shift suggests a nuanced decline in mental health after the pandemic declaration day. Likewise, topics 1, 2, 8, and 9 in the second week contained more alcohol- and liquor-related keywords (such as *drink*, *beer*, *bottle*, *liquor*, *store*, and *drunk*), suggesting use of alcohol as the main substance during this period. Nevertheless, there were no major terms in the topic analysis that could support prescription medication use in the second week.

In conclusion, our detailed analysis on 7 days before and after the pandemic declaration day highlights the immediate impact on the use of substances, particularly alcohol and prescription medication.

Theme Trend Analysis and Substance Distribution for Question 3

As per our keyword-based theme analysis, COVID-19 had a notably significant impact on the discussion of SU. The early pandemic period showed a significant rise in alcohol and cannabinoids associated with 2 main themes as follows: COVID-19 and social isolation. This surge was most evident at the onset of the pandemic in early 2020, likely reflecting a response to the stress, uncertainty, and lifestyle changes imposed by the health crisis. The data indicated that these increases were particularly influenced by COVID-19–related factors, with social and economic aspects also playing a role. In contrast, factors related to supply and medical disruptions did not drastically affect use patterns. This concentrated spike in alcohol and cannabinoid use during challenging periods highlights the broader impact of the pandemic on SU behaviors.

k-Means Clustering Analysis for Question 5

From the k-means clustering, we identified 10 main clusters as an indication of what was discussed in the pandemic year as follows: beverage variety, challenges and relaxation, drunk chronicles and emotions, explicit language and substance talk, moments of intoxication and interaction, smoking chronicles, socializing and nights out, SU experiences, wine and spirits exploration, and diverse conversations. The diverse conversation cluster includes all the remaining tweets that do not belong to particular clusters. Hence, the number of posts in it has the highest counts. Excluding this cluster, SU-associated posts were mostly seen in socializing and nights out, followed by SU experiences and smoking chronicles as the 3 main top discussions.

Thematic Analysis for Question 4

Heat Map Analysis

The heat map analysis provided insightful revelations regarding the factors influencing SU discourse, highlighting COVID-19, economic stress, mental health concerns, and alterations in drug supply as the principal elements. Specifically, there is a stronger correlation between the “COVID-19” theme and cannabinoid use, possibly signifying an increase in this substance’s consumption as a direct response to the pandemic’s stressors. The “economic” theme shows a somewhat lower yet noticeable correlation with alcohol, which might reflect economic uncertainty’s impact on alcohol consumption. The “social” theme has a less pronounced correlation across all substance types, implying that social factors had a milder influence on SU during this period. “mental health” has a moderate correlation with both cannabinoids and alcohol, highlighting these as coping mechanisms during mentally challenging times. “supply disruption” shows a varied correlation but is not significantly linked with any substance, suggesting that supply issues did not drastically alter consumption patterns. Finally, “medical disruption” seems to have the least correlation with SU, suggesting that medical service disruptions during the pandemic had minimal influence on the consumption of these substances. Overall, the heat map indicates that COVID-19–related factors had the most significant correlation with changes in SU, with

XSL•FO
RenderX

economic and mental health factors also being relevant but to a lesser extent.

Factor Analysis

The factor analysis gave insights into a combination of themes that had an impact on SU. Factor 1 indicated that mental health was the leading factor. Factor 2 was strongly and positively associated with the economic theme, suggesting that this factor could represent financial stress or economic consequences of the pandemic. The social theme had a moderate negative loading on factor 2, implying that social aspects may decrease in relevance as economic concerns increase or vice versa. Factor 3 showed a very strong negative loading with the medical disruption theme, indicating that this factor was significantly influenced by disruptions in medical services. This could represent the strain on health care systems and the impact of health care access on the population. Mental health and supply disruption themes had a strong positive loading on factor 4, implying that this factor may represent the psychological impact of the pandemic and its influence on drug supply chains.

In summary, the factor analysis suggested that economic and mental health themes were major dimensions of the pandemic's impact, with medical disruptions also playing a significant but negatively associated role.

Comparison With GPT-3 for Question 6

Our comparative analysis with the GPT-3 model yielded valuable insights into the effectiveness of powerful generic models in identifying hidden contexts in domain-specific data, particularly related to drug use in tweets. The experiment involved using a prompt to classify tweets as either related or unrelated to SU. The results demonstrated a substantial discrepancy in accuracy between human verification and GPT-3. When comparing the randomly sampled predicted positive tweets, human experts confirmed the accuracy of 95.23%, whereas GPT-3 verified only 53.73% of the tweets as accurate. This notable difference underscores the limitations of generic models such as GPT-3 in accurately discerning domain-specific nuances. Although we have not performed a detailed analysis to find out the reason behind this discrepancy, we anticipate the limitation of contextual awareness as a primary reason for this, as indicated in the studies by Ray [81] and Moradi et al [82]. For instance, Moradi et al [82] highlighted similar cases where GPT-3 underperformed in the biomedical corpora in comparison to domain-specific pretrained model BioBERT [82]. By contrast, generic pretrained models such as ours can provide rich contextual understanding as they are pretrained solely on social media data, making them powerful in understanding slang-like languages. Thus, the limitation in GPT-3 is well addressed by our custom model pretrained on domain-specific data.

Real-Time Integration for Question 7

The successful integration of our trained model into the practical application Tri County Prevention Infrastructure [80], particularly within the social media section tailored for Ohio, marks a significant achievement. This integration empowers real-time users by allowing them to visually explore the distribution of substance-use posts in both temporal and spatial dimensions. For instance, the users can explore and analyze the trend of any substance (eg, alcohol) in real time and take immediate actions to mitigate the use in the areas of interest. In addition, the applicability of our models' integration is promising during crisis periods such as the COVID-19 pandemic, when physical intervention is unfeasible.

Limitations

Our study has several limitations. Initially, data inconsistencies in certain months were due to incomplete datasets from the sources [63]. Moreover, our analysis was confined to English-language posts, potentially excluding non-English speaking users and thus not reflecting the full spectrum of users during the study period. The initial annotated data used for the training model were collected from a specific time frame (January 2020 through April 2020). The selection of data from this particular time frame could have introduced some bias in the SU identification process. In addition, the consideration of precision as our primary evaluation metric during iterative fine-tuning steps could have missed real SU posts, limiting to the small spectrum of patterns learned by the model and leading to overfitting. Also, the overall accuracy of the classifier reached 80%, which could have led to non-SU posts being identified as SU posts and vice versa. Consequently, this could actually deviate the count of SU posts identified in our study, thus deviating from trend studies. Although the choice of classifier, RoBERTa, seems to have performed better, the identification of SU tweet posts for multiple sequences could have been misclassified. Likewise, the limited labeled dataset during fine-tuning could have underfitted the performance in the initial rounds. While we used HITL [61] in our iterative fine-tuning approach to enrich the annotated data, the human reviewers involved in the process were only tasked with reviewing model predictions without providing feedback. This lack of active human feedback may have limited the model's capacity for improvement as corrections to errors and mispredictions or rewarding accurate predictions could have enhanced its performance further. In the future, incorporating a full HITL at different stages of model development could significantly improve accuracy and model refinement. Finally, the scope of keywords used in processing tweet data may have been too narrow, possibly leading to an overrepresentation of certain themes and factors in our results.

Future Work

This study only considered text data for the identification of SU. Future research could use multimedia, such as images and videos, to enhance the accuracy of the identification of SU. Furthermore, our iterative fine-tuning approach could be enhanced through active learning [62], where the most critical samples are selected for annotation in each iteration, optimizing model performance. Another potential improvement involves incorporating full HITL feedback [61], allowing human reviewers not only to review but also to correct errors or reward accurate predictions. This approach could significantly refine model accuracy. In addition, a user-level analysis could be conducted to investigate factors influencing the intention and purpose behind substance misuse. In addition to this, demographic factors such as age, gender, race, emotion, socioeconomic status, personality trait, and mental and physical

XSL•FO
RenderX

health status could be considered for investigation to understand the most impacted cohort during the pandemic. By understanding these cohorts and factors, we can develop strategies and interventions to prevent and control SU during global crises.

Conclusions

In this study, we conducted an extensive infodemiology analysis of Twitter posts from 2019 to 2021, focusing on SU patterns during the COVID-19 pandemic. Using a deep learning model (RoBERTa) alongside techniques with human involvement in iterative fine-tuning, our classifier achieved an optimal accuracy of 80%, even with limited resources. This performance is notable as even a powerful state-of-the-art model such as GPT-3 struggled with domain-specific data such as SU.

In summary, the results from our study showed the key patterns in SU trends during both the pandemic and overall study periods. The analysis of the pandemic period has shown that COVID-19 had a huge impact on the influx of SU. As indicated by trend analysis, the numbers were higher during the peak pandemic period, mainly between March and October 2020. Furthermore, the theme analysis showed a higher association of SU posts with COVID-19 and social themes in comparison to other themes during the pandemic period. In addition to this, the immediate declaration of the pandemic introduced stress and anxiety in public, as evidenced by our LDA topic analysis, causing a significant rise in SU (21% in just 3 days), primarily in readily available substances such as alcohol and prescription medication. These findings suggest that the authorities should pay attention to key factors such as social isolation, stress, and anxiety, and focus on strengthening regulations around the sale of accessible substances such as alcohol, prescription medications, and cannabinoids (though not legal in all areas) to have control the SU during the global COVID-19 pandemic crises. By contrast, economic, mental health, and supply disruptions seem to be the major contributing factors for SU throughout the study period, as indicated by our factor analysis, with cannabinoids, alcohol, and stimulants as dominating substances. Thus, public health agencies should focus on controlling the economic and mental health of global citizens as key actions, alongside surveilling drug supplies, in order to control global SU.

In summary, our study demonstrates the applicability of social media data used along with a deep learning model to analyze trends in global issues such as SU. The findings and methodology from this study can help public health sectors develop real-time strategies and prevent SU during future crises.

Acknowledgments

This work was supported by the Substance Abuse and Mental Health Services Administration Strategic Prevention Framework-19 (Grant No. 6H79SP081502). We gratefully acknowledge Megan Anderson, Sheryl Chatfield, Kaylie Kenne, Kayla Marker, Olivia Anderson, and Cassidy Shokles (Center for Public Policy & Health, College of Public Health, Kent State University) and Anthony Coetzer-Liversage (Social Sciences Research Center, University of Rhode Island) for their assistance with data annotation. We also sincerely thank the editors and reviewers for their valuable feedback, which greatly improved the manuscript.

Data Availability

The data and code supporting this study are publicly available on GitHub [83].

Authors' Contributions

JM contributed to the conceptualization, methodology, investigation, formal analysis, model development, and writing of the original draft. RJ assisted in conceptualization and supervised the study. JZ provided feedback on the analyses, while JK contributed to data curation and validation. All authors reviewed and approved the final manuscript.

Abstract

Background: In the past decade, *hashtag feminism* has emerged in Mexico as a prevalent strategy to build social movements against gender-based violence (GBV). For example, during the global "16 Days of Activism Against GBV" campaign held between November 25 and December 10 each year, Mexico-based nongovernmental organizations (NGOs) turn to X (formerly known as Twitter) to share messages. Despite this prevalence, there is limited research on the type of information shared by these NGO activists on social media and the public's engagement with these messages.

Objective: This study aims to explore the themes covered by Mexican NGOs on X and examine what types of messages related to GBV potentially resonated more with the public.

Methods: We collated and reviewed posts (commonly known as tweets) published in Spanish on the platform X by Mexico-based NGOs between November 25 and December 10 of 2020, 2021, and 2022, a period when digital interactions increased during the COVID-19 pandemic. We then extracted posts using the following 4 hashtags: #16días, #16DiasdeActivismo, or #16DíasdeActivismo; #25N or #25Noviembre; #DiaNaranja or #DíaNaranja; and #PintaElMundoDeNaranja. We subsequently assessed the number of likes each post had and retained the top 200 posts from each year with the highest number of likes. We used the iterative content analysis process and the inductive 6-step qualitative thematic analysis method in NVivo software to code and analyze the final 600 posts.

Results: Five themes emerged from the 16 Days of Activism Against GBV campaigns, covering both knowledge-sharing and activism-generating messages as follows: (1) activism and how to be an activist, (2) types of GBV most commonly highlighted in posts, (3) changing public discourse surrounding GBV, (4) GBV as a violation of human rights, and (5) the COVID-19 pandemic's impact on GBV. Most of the messages on these posts exclusively mentioned women and younger girls, while a few included adolescents. Gaps in the representation of vulnerable populations were also found.

Conclusions: The posts from this campaign that were highly liked by the public reflect some of the most significant societal issues currently present in the country. Our results could help guide further GBV campaigns. Still, further research related to hashtag feminism by Mexico-based NGOs on GBV is needed to understand the population that NGOs reach and how the messages shared on these campaigns translate into activism on online and offline social media platforms.

gender-based violence; Mexico; hashtag activism; feminist social activism; hashtag feminism; Twitter; X; nongovernmental organization; social media

Introduction

Background

Violence against women and girls, also commonly referred to as gender-based violence (GBV), is one of the world's most persistent forms of human rights violations and a major problem in the public health and clinical health arenas [1,2]. Specifically, GBV continues to be a serious problem in Mexico, as 70% of the women aged ≥15 years have experienced at least one incidence of GBV throughout their lives [3]. GBV takes many forms, with the most prevalent forms in Mexican society being psychological and sexual violence [3]. Disappearances and femicide, which is the intentional murder of a girl or woman because of her gender, are also common forms of violence in Mexico, with approximately 25% of women, adolescent girls, and young girls experiencing these forms of violence [4,5]. The COVID-19 pandemic increased the risk of violence against women, adolescents, and girls; women in North America, Central America, and South America were disproportionately affected by GBV during the pandemic [6]. Particularly in Mexico, domestic violence increased by more than 15% between 2020 and 2021 [7]. In 2020, the number of emergency calls related to violence against women increased by >30%, and the requests for support due to GBV increased by 40% [8,9]. Forms of structural GBV, such as violence at the social and economic levels, were also impacted during the COVID-19 pandemic in Mexico, for example, by the continuous increase in unpaid domestic and care work [10]. In addition, digital violence, which involves gender-based acts of violence through communication technology or digital media, such as image-based abuse, cyberstalking, blackmailing, and online harassment, increased in visibility in Mexico in the years surrounding the limitations of social interactions [10-13].

In Mexico, government institutions provide some forms of social support in the fight against the various forms of GBV, although important gaps in coverage are addressed by nongovernmental organizations (NGOs). Specifically, NGOs provide health care, psychosocial support, and legal aid for women, adolescents, and girls experiencing this type of violence [14]. As GBV and gender inequality became more visible during the COVID-19 pandemic, feminist movements, such as hashtag activism, feminist social activism, and hashtag feminism, in which NGOs actively collaborate, also became more visible [15]. Hashtag activism can facilitate social change, policy formation, and the provision of resources for the public [16]. Feminist social activism, popular since the late 2000s and present in Mexico since 2011, involves feminist individuals and organizations using social media for online civic engagement to denounce GBV and related aspects (such as sexism and gender discrimination); initiate social movements; and connect to share experiences, support, and resources, to name a few [17].

Online engagement to denounce GBV and other forms of gender-inequitable practices includes the initiation of social movements by connecting individuals to share their experiences, provide support, and offer sources of support. Hashtag feminism is a form of activism that combines hashtag activism with feminist social activism using specific hashtags across different digital platforms to call for action by sharing information and stories, connecting people, and organizing and mobilizing events against gender inequities [18-20]. NGOs have played a significant role in catalyzing hashtag feminist movements on GBV worldwide and in Mexico by engaging stakeholders and the general public through dialogue and community-building practices, mainly through Facebook and X (formerly known as Twitter; X Corp) [21-29]. An example of this is the 16 Days of Activism Against GBV, an annual international campaign led by civil society that runs from November 25, the International Day for the Elimination of Violence Against Women, to December 10, Human Rights Day [30,31]. The intention of this global campaign is to call for the prevention and elimination of violence against girls, adolescents, and women in all its different forms, including child marriage, sexual harassment, and intimate partner violence, to name a few [31,32].

Hashtag feminist movements stand to make a great impact in Mexican society, as social media use is widespread. In 2021, 89.2% of the internet users in Mexico connected to the internet daily, and 89.8% used it to access social media [33]. As of January 2022, Mexico ranked ninth in the world for most X users, with 13.9 million users [34]. Similar to what happened in other countries, digital interactions increased during the COVID-19 pandemic in Mexico, and the use of social media to promote strategies against violence, such as support groups, helplines, and screening for violence, became more popular [35-37]. Despite the prevalent use of X in the world and in Mexico, research is limited in regard to hashtag activism and hashtag feminism through X on GBV, specifically on interpersonal and sexual violence [22,38-40]. To our knowledge, only a few publications exist on feminist social activism in Mexico that are specific to GBV at the local level [17,41]. Furthermore, the X content from campaigns that address the umbrella of different types of GBV by Mexico-based NGOs has not previously been explored. Understanding the public's engagement on the GBV hashtag feminist campaigns is critical, as this can inform future GBV campaigns and provide valuable information to NGOs, governments, and researchers for tailored online and offline GBV prevention and intervention strategies.

This Study

To fill this gap, this research aimed to describe the range of GBV themes that Mexican NGOs posted on X during the annual 16 Days of Activism Against GBV campaign during the COVID-19 pandemic (from 2020 to 2022) and elucidate what types of messages related to GBV the public engaged with the most across and between the 3 different years. It is important to specify that while in Mexico the more specific term "violence against women" is commonly used, as it is the term described in the General Law on Women's Access to a Life Free from Violence first published in 2007 [3], this research followed the

XSL•FO
RenderX

term GBV, as it is an umbrella term commonly used interchangeably [42] with violence against women and is the term used in the global campaign that is the focus of our investigation. We sought to describe the GBV themes raised by Mexico-based NGOs on X during these global campaigns and, based on the public's engagement, how the main content themes of posts (commonly known as tweets) compare between the 3 different years. Our findings can provide information on how these campaigns and the public's engagement could modify the agenda against GBV at different societal levels that was weakened during the COVID-19 pandemic [43] by contributing information on the topics that are generating the attention of the public, providing voice to certain communities, and adapting these results into current or future political or legal initiatives.

Methods

Study Design and Data Collection

Our research methodology followed a thematic content analysis of posts posted by Mexico-based NGOs during the annual 16 Days of Activism Against GBV campaign from 2020 to 2022. The following four hashtags chosen for this analysis were based on informal exploration on X of relevant hashtags used by Mexico-based NGOs during the campaign in 2020, 2021, and 2022: (1) the overall name of the campaign and its variations, namely #16días, #16DiasdeActivismo, or #16DíasdeActivismo (#16daysofactivism); (2) the first day of the campaign and the International Day for the Elimination of Violence Against Women (November 25), namely #25N or #25deNoviembre; (3) Orange Day, which occurs on the 25th of each month to create awareness and prevent violence toward girls and women, namely #DiaNaranja and #DíaNaranja (#OrangeDay); and (4) a related but broader hashtag, namely #PintaElMundoDeNaranja (#PaintTheWorldOrange). Given that the hashtag #10D, referring to December 10, the last day of the campaign and Human Rights Day, is also used annually in Argentina for democratic campaigns, we excluded it from analysis as a strategy to ensure data focused on the GBV campaign.

During data collection, the advanced search option from X was used to filter data based on the following study inclusion criteria: (1) only original content (no reposts or retweets); (2) included one of the hashtags used by Mexico-based NGOs during the campaign that were selected for this analysis (#16días, #16DiasdeActivismo, #16DíasdeActivismo, #25N, #25deNoviembre, #DiaNaranja, #DíaNaranja, or #PintaElMundoDeNaranja); (3) published in Spanish; (4) posted by a public X user with "non-governmental and nonprofit organization" as the professional category in order to only collect posts from local, state, national, or global NGOs; (5) the location of the X user marked as Mexico or a city or state in it; and (6) posted between November 25 and December 10 of 2020, 2021, and 2022, to align with the dates the campaign occurred. We used the Zeeschuimer and the 4CAT research tools to capture and download data from X. Zeeschuimer is a browser extension that collects data from social media sites, such as Instagram, TikTok, and X, while 4CAT is a research tool that can be connected to Zeeschuimer to store and download the data collected by the browser extension [44].

Data Cleaning

Posts posted between November 25 and December 10 of 2020, 2021, and 2022 were downloaded from 4CAT to a Microsoft Excel spreadsheet in August 2023. Posts that included videos (<1 min) and informational graphics were also included in the analysis. A total of 1914 posts (n=662, 34.59% for 2020; n=654, 34.17% for 2021; and n=598, 31.24% for 2022) were collected for the hashtags and the selected time period. To avoid duplicates, identical posts published during the same campaign year were collapsed and considered as one individual post. The collected posts were reviewed to ensure they met the inclusion criteria (only posts in Spanish, X user being an NGO, and location of the X user in Mexico).

We used the number of likes received by a post as the metric to determine the public's interest in and engagement with a post [45]. The frequency of likes has been previously used in the literature, including studies on GBV and feminist activism, to measure the public's engagement [21,39,46-50]. Reposts, which have been considered another form of public engagement in which the public contributes and creates content through reposting or forwarding a post [22], were not included in the analysis in order to focus on an original and representative set of posts posted by Mexico-based NGOs that participated in the 16 Days of Activism Against GBV campaigns.

We limited the analysis to the top 200 posts per year with the most likes (N=600 total posts) to assess the messages that generated the most engagement from the public. This analytic decision was based on previously published literature that has demonstrated that at least 500 posts are sufficient to identify themes and understand how individuals engage in health behaviors on X [51,52]. In the event of identical posts from different NGOs, we collapsed the number of likes.

Data Coding and Analysis

After obtaining and cleaning the data, the final list of 600 posts was uploaded into NVivo (version 14; Lumivero) for coding and analysis in the original language. We retained the original language of the posts to more accurately capture the cultural connotations and local meaning of the messages [53]. We completed an iterative content analysis process and a 6-step inductive thematic content analysis to identify and categorize the content of the posts into themes and explore socially produced and reproduced experiences [21,22,54]. These systematic approaches to interpreting qualitative research data have been used by other researchers when conducting thematic content analysis of social media data, including X hashtags in GBV campaigns [38,55-59]. The thematic process involved familiarization with the data, selection of keywords, coding, theme development, interpretation of themes, and development of a conceptual model [55]. An iterative inductive content analysis approach [60] was followed for the creation of the codebook by the first author and 2 research assistants (Yxchel Tejeda and Julia Godinez), as code categorization and subcategorization were extracted from the posts. Both research assistants were bilingual and were trained in thematic content analysis. Regular debriefing meetings between the primary author and the 2 research assistants took place during the coding and analysis process to refine the working codebook, discuss

XSL•FO
RenderX

findings and emergent themes, resolve any coding discrepancies, and address any potential questions. The research team used NVivo (version 14) for coding and analysis. After the initial analysis, data were translated from Spanish to English by the first author (MM), who is bilingual.

Ethical Considerations

This study used publicly available, deidentified posts and did not directly involve human participants. Per the US Department of Health and Human Services' regulations for the protection of human subjects in research (45 CFR 46), approval from a research ethics committee was therefore not required or obtained. However, we adhered to ethical guidelines for handling and analyzing publicly available data, ensuring user anonymity and data privacy throughout the research process, including findings reported in this study.

Results

Overview

The 600 posts included in the final sample came from 61 different Mexico-based organizations. The number of likes for each post ranged from 9 to 2095. As shown in Table 1, the hashtag using the campaign's name (16 Days of Activism Against GBV) was the most frequently used hashtag in all 3 campaign years.

Table 1. Frequency of hashtags mentioned on most liked posts per campaign year by Mexico-based nongovernmental organizations.

Hashtag	2020, n (%)	2021, n (%)	2022, n (%)	Total, n (%)
#25N or #25Noviembre (n=216)	56 (25.9)	58 (26.9)	102 (47.2)	216 (100)
#DiaNaranja or #DíaNaranja (n=283)	113 (39.9)	111 (39.2)	59 (20.8)	283 (100)
#16días, #16DiasdeActivismo, or #16DíasdeActivismo (n=528)	167 (31.6)	204 (38.6)	157 (29.7)	528 (100)
#PintaElMundoDeNaranja (n=76)	49 (64.5)	22 (28.9)	5 (6.6)	76 (100)

The following five themes emerged across the 3 campaign years: (1) activism and how to be an activist, (2) types of GBV most commonly highlighted in posts, (3) changing public discourse surrounding GBV, (4) GBV as a violation of human rights, and (5) the impact of the COVID-19 pandemic on GBV. Within some of these themes, we also identified several cross-cutting subthemes, as described subsequently.

Theme 1: Activism and How to Be an Activist

The most common theme among the highly liked posts covered descriptions of what the 16 Days of Activism Against GBV campaign is, along with what activism is and how to be an activist (Table 2). Many of these posts were invitations to join the campaign or be activists. Other posts stressed that activism to support the rights of women and girls does not stop when the campaign stops but should be practiced on a regular basis. Invitations, live updates, and links to different types of events, such as marches, podcasts, and webinars organized during the campaigns, were also shared in these posts.

Table 2. Representative quotes from theme 1 (activism and how to be an activist).

Subthemes	Examples (posts translated into English)	Examples (posts in original language)
Description of the campaign	• "During these #16Días and all year long, stand in solidarity with women's rights activists and support feminist movements to resist the rollback of women's and girls' rights. #Únete #25N" [2022 campaign] • "What are the #16Días de activismo? It is a call to action and a reminder that violence against women and girls is the most widespread human rights violation around the world. #DíaNaranja Take action to end violence against women and girls." [2022 campaign]	• "Durante estos #16Días y todo el año, solidarízate con las activistas de los derechos de las mujeres y apoya a los movimientos feministas para resistir el retroceso de los derechos de las mujeres y las niñas. #Únete #25N" [Campaña 2022] • "¿Qué son los #16Días de activismo? Es un llamado a la acción y un recordatorio de que la violencia contra las mujeres y las niñas es la violación de derechos humanos más extendida en todo el mundo. #DíaNaranja Actúa para poner fin a la violencia contra las mujeres y las niñas." [Campaña 2022]
Campaign events	• "Women musicians, visual artists, activists, journalists, photographers and filmmakers join their voices to create #25NMás16, a sound, visual and informative piece promoted by the Initiative #SpotlightMX #DíaNaranja #Únete #16Días" [2020 campaign]	• "Mujeres músicas, artistas visuales, activistas, periodistas, fotógrafas y cineastas unen sus voces para crear #25NMás16, una pieza sonora, visual e informativa impulsada por la Iniciativa #SpotlightMX #DíaNaranja #Únete #16Días" [Campaña 2020]
Geographical examples	• "#25N| This is a fight for all women 'Neither in Tijuana, nor in Chiapas, nor in this city, NOT ONE MORE MURDERED' #NiUnaMenos #VivasNosQueremos" [2020 campaign]	• #25N| Esta es una lucha de todas las mujeres "Ni en Tijuana, ni en Chiapas, ni en esta ciudad, NI UNA ASESINADA MÁS" #NiUnaMenos #VivasNosQueremos" [Campaña 2020]

XSL•FO
RenderX

Different NGOs used different types of communication materials to explain the campaign's purpose and why and how to be an activist, including songs, short videos, and celebrity involvement. Particularly in the 2021 campaign, posts included images and quotes related to the campaign from musicians, politicians, ambassadors, NGO directors and representatives, and leaders in industry and sport. Figure 1 shows examples of visuals used in highly liked posts for the 16 Days of Activism Against GBV campaigns in 2020, 2021, and 2022.

Figure 1. Examples of visuals used by Mexico-based nongovernmental organizations in the frequently liked X (formerly known as Twitter) posts for the 16 Days of Activism Against Gender-Based Violence campaigns in 2020, 2021, and 2022.

Posts' messages on activism and how to be an activist were mainly generalized to the national level or provided data at a country level, although some included specific activities and examples of GBV cases from different municipalities, states, and, in 3 instances, other countries.

Theme 2: Types of GBV Most Commonly Highlighted in Posts

Many posts consisted of information about a specific type of violence (Table 3). Sexual violence was the most common type of violence found in these posts, followed by messages related to trafficking, disappearances, and femicide. These types of posts included data on the number of femicides or women and girls who have disappeared in the country and advice on what needs to change to prevent trafficking. Specific examples of women who have experienced GBV, particularly sexual violence and torture, were also included. Violence at home and physical violence were other forms of GBV that were also commonly present in these posts. Posts about digital violence were present in the data as well, particularly in 2020, at the start of the COVID-19 pandemic.

XSL•FO
RenderX

Table 3. Representative quotes from theme 2 (types of gender-based violence most commonly highlighted in posts).

Subthemes	Examples (posts translated into English)	Examples (posts in original language)
Sexual violence	• "Let us join forces against those who attempt to blur the boundaries of sexual consent, blame victims, and excuse perpetrators. During the #16Days of Activism, let's say it loud and clear: NO IS NO. #Únete #DíaNaranja" [2020 campaign]	• "Unamos nuestros esfuerzos contra quienes intenten desdibujar los límites del consentimiento sexual, culpar a las víctimas y excusar a los agresores. Durante los #16Días de Activismo, digámoslo alto y claro: NO ES NO. #Únete #DíaNaranja" [Campaña 2020]
Femicides and trafficking	• "Mexico closes the year with the terrible number of 27 thousand missing girls and women. Within the framework of #16Días of Activism, it is essential to demand differentiated strategies with a gender perspective to find them all" [2022 campaign] • "In Mexico, 11 femicides occur DAILY. Today #25N International Day for the Elimination of Violence against Women, we raise our voices for freedom, security, justice and sisterhood for all girls and women in Mexico. #NiUnaMas #VivasNosQueremos #DiaNaranja" [2020 campaign]	• "México cierra el año con la terrible cifra de 27 mil niñas y mujeres desaparecidas. En el marco de #16Días de activismo es fundamental exigir estrategias diferenciadas con perspectiva de género para encontrarlas a todas" [Campaña 2022] • "En México ocurren 11 feminicidios DIARIOS. Hoy #25N Día Internacional de la Eliminación de la Violencia contra la Mujer, alzamos la voz por la libertad, seguridad, justicia y sororidad para con todas las niñas y mujeres en México. #NiUnaMas #VivasNosQueremos #DiaNaranja" [Campaña 2020]
Violence at home	• "Women, girls and adolescents need to have peace of mind in their home and feel that their home is a safe and reliable space. Their home is NOT a space of #violence. Let's make families and homes #EspaciosSeguros! #25N #PintaElMundoDeNaranja #16Días" [2021 campaign]	• "Las mujeres, niñas y adolescentes necesitan tener tranquilidad en su hogar y sentir que su casa es un espacio seguro y confiable. Su hogar NO es un espacio de #violencia. ¡Hagamos de las familias y los hogares #EspaciosSeguros! #25N #PintaElMundoDeNaranja #16Días" [Campaña 2021]
Digital violence	• "The increase in internet use during #COVID19 has made women and girls targets of online violence. In these #16Días of Activism, #pintaelmundodenaranja using your networks to raise awareness and promote solidarity. #DíaNaranja #Únete" [2020 campaign]	• "El incremento del uso de internet durante #COVID19 ha convertido a mujeres y niñas en blanco de violencias en línea. En estos #16Días de Activismo, #pintaelmundodenaranja usando tus redes para concientizar y fomentar la solidaridad. #DíaNaranja #Únete" [Campaña 2020]
Physical violence	• " Did you know that 1 in 3 women in the world has suffered physical or sexual violence throughout their lives? Share this post and #Únete the #16días of activism to end this global pandemic. #25N" [2021 campaign]	• " ¿Sabías que 1 de cada 3 mujeres en el mundo ha sufrido violencia física o sexual a lo largo de su vida? Comparte este post y #Únete a los #16días de activismo para acabar con esta pandemia mundial. #25N" [Campaña 2021]

Other forms of violence, such as the lack of access to sexual and reproductive resources, obstetric violence, vicarious violence, and precarious work, were present in posts, but they were not as common as sexual violence, femicide, and digital violence. Violence against women in the form of harassment in specific locations, such as school and at work, was also highlighted by the campaign but to a lesser extent.

Theme 3: Changing Public Discourse Surrounding GBV

Posts in this theme centered on changing current narratives in Mexican society surrounding GBV that blame and silence survivors and normalize violence (Table 4). The posts provided examples of how to change the narrative, such as believing the victim, not excusing the perpetrator, and reporting any form of violence. The actors responsible for making these changes included both individuals and institutions. At the individual level, most posts were not targeted at a specific gender; however, some did aim toward male individuals and their role in eradicating GBV. Some highly liked posts were focused on female individuals, while other posts were specific to inviting both men and women to become activists and eradicate GBV. Throughout the 3 campaign years, the highly liked posts provided specific information about GBV toward women or women and younger girls. A few highly liked posts included adolescents in the messages, and, when included, these posts were about violence against younger girls and adolescents or against younger girls, adolescents, and women. At the institutional level, posts provided reasons for the importance of these groups in combating GBV, such as health and government personnel providing help to women after experiencing some form of GBV, while also providing examples of what these institutions can do, such as treating survivors of GBV with dignity and defending the rights of women, adolescents, and girls.

XSL•FO
RenderX

Table 4. Representative quotes from theme 3 (changing public discourse surrounding gender-based violence).

Subthemes	Examples (posts translated into English)	Examples (posts in original language)
Believe survivors	• "Every time a woman talks about her experience of sexual violence and we don't believe her, rape culture grows stronger. Every time you hear a survivor's story: 1-Listen. 2-Believe. 3-Support. #DíaNaranja #16Días #Únete" [2020 campaign]	• "Cada vez que una mujer habla de su experiencia de violencia sexual y no le creemos, la cultura de la violación se hace más fuerte. Cada vez que escuches la historia de una sobreviviente: 1-Escucha. 2-Cree. 3-Apoya. #DíaNaranja #16Días #Únete" [Campaña 2020]
End the silence	• "If you face violence, don't be silent, raise your voice. Call 911 for help immediately and tell your trusted people. #16Días #DíaNaranja" [2021 campaign] • "Report when you see: Abuse Harassment on the street Sexist jokes Unwanted behavior Inappropriate sexual comments Sexual harassment is never acceptable. #16Días #Únete #DíaNaranja" [2020 campaign]	• "Si enfrentas violencia, no te calles, alza la voz. Pide ayuda inmediatamente al 911 y cuéntalo a tus personas de confianza. #16Días #DíaNaranja" [Campaña 2021] • "Denuncia cuando veas: Abuso Acoso en la calle Bromas sexistas Comportamiento no deseado Comentarios sexuales inapropiados El acoso sexual nunca es aceptable. #16Días #Únete #DíaNaranja" [Campaña 2020]
Call out perpetrators' actions	• "Don't be an accomplice to those who commit violence, don't look the other way. Speak up, intervene and show your support for survivors during the #16Días, and every day. #Únete #DíaNaranja" [2020 campaign]	• "No seas cómplice de quien ejerce violencia, no mires a otro lado. Habla, interviene y muestra tu apoyo a las sobrevivientes durante los #16Días, y todos los días. #Únete #DíaNaranja" [Campaña 2020]
Engage men	• "As men we have to reflect, question ourselves, inform ourselves and act. #25N Let's build relationships of respect, peace and equality! " [2022 campaign]	• "Como hombres nos toca reflexionar, cuestionarnos, informarnos y actuar. #25N ¡Construyamos relaciones de respeto, paz e igualdad! " [Campaña 2022]
Focus on women and younger girls	• "Eliminating violence against girls and adolescents is everyone's task. Get informed and learn about different ways in which you can prevent gender violence. #16Días #DíaNaranja" [2021 campaign] • "Violence will affect 1 in 3 girls and women throughout their lives. This must stop! #PintaElMundoDeNaranja and unite against violence." [2020 campaign]	• "Eliminar la violencia contra las niñas y las adolescentes es tarea de todas y todos. Infórmate y conoce diversas formas en que tú puedes prevenir la violencia de género. #16Días #DíaNaranja" [Campaña 2021] • "La violencia afectará a 1 de cada 3 niñas y mujeres a lo largo de su vida. ¡Esto debe parar! #PintaElMundoDeNaranja y únete contra la violencia." [Campaña 2020]
Responsibility of societal institutions	• "People in leadership must implement prevention measures that address inequalities in power relations between genders, which are at the root of violence against women and girls #16Días #DíaNaranja" [2021 campaign] • "Health providers can also defend the life and health of girls who have been forced to become mothers. Taking care of the health of survivors also involves having the ability to treat them humanely and with dignity. They are #GirlsNotMothers. #25N" [2021 campaign]	• "Las personas en liderazgo, deben poner en marcha medidas de prevención que hagan frente a las desigualdades en las relaciones de poder entre los géneros, que se encuentran en la raíz de la violencia contra las mujeres y las niñas. #16Días #DíaNaranja" [Campaña 2021] • "Las personas proveedoras de salud también pueden defender la vida y la salud de las niñas que han sido forzadas a ser madres. Cuidar la salud de las sobrevivientes también pasa por tener la capacidad de darles un trato humano y digno. Son #NiñasNoMadres. #25N" [Campaña 2021]

Theme 4: GBV as a Violation of Human Rights

Posts related to GBV as a human rights concern rooted in gender inequalities and power imbalances were also common in the 3 campaign years (Table 5). These posts that stated the importance of challenging inequitable gender norms to promote equity and justice for girls and women were highly liked during the 3 campaign years. Particularly, for posts from 2020 related to justice and equity, many highly liked posts described real-life events of women in Mexico who had experienced sexual violence, wrongful convictions, and unjust incarcerations.

The focus on inequities did not stop at gender inequities. Posts also focused on violence toward specific vulnerable groups, such as people with disabilities, migrants, and sexual minority groups, and they were also found in the highly liked posts for the 3 campaign years, especially in 2021 and 2022. The two most common messages among posts related to vulnerable groups were (1) events to visualize the GBV that migrants experience in Mexico and (2) information on vulnerable populations being at a higher risk of experiencing GBV.

XSL•FO
RenderX

Table 5. Representative quotes from theme 4 (gender-based violence as a violation of human rights).

Subthemes	Examples (posts translated into English)	Examples (posts in original language)
Human rights violation	"Violence against women is the most widespread violation of human rights in the world and the latest UN data show that the greatest threat to women and girls lies in the people in their immediate environment. #16Días #YaEsYa #DíaNaranja #Únete" [2022 campaign]	"La violencia contras las mujeres es la violación más generalizada de los derechos humanos en el mundo y los últimos datos de ONU demuestran que la mayor amenaza para las mujeres y las niñas reside en las personas de su entorno más cercano. #16Días #YaEsYa #DíaNaranja #Únete" [Campaña 2022]
Origins in gender inequity	"The origin of violence is discrimination and gender inequality, as well as gender stereotypes and harmful masculinities still in force in our societies. #16Días #DíaNaranja #Únete" [2021 campaign]	"El origen de la violencia es la discriminación y la desigualdad de género, así como los estereotipos de género y las masculinidades nocivas aún vigentes en nuestras sociedades. #16Días #DíaNaranja #Únete" [Campaña 2021]
Violence toward vulnerable groups	"Inequality, poverty, ethnic origin, disability, immigration status, among others, increase the vulnerability of women and girls. Let's end violence against women and girls NOW! #16Días #DíaNaranja" [2021 campaign]	"La desigualdad, la pobreza, el origen étnico, la discapacidad, el estatus #migratorio, entre otros, aumentan la vulnerabilidad de las mujeres y las niñas. ¡Pongamos fin a la violencia contra las mujeres y las niñas YA! #16Días #DíaNaranja" [Campaña 2021]

Theme 5: The Impact of the COVID-19 Pandemic on GBV

Finally, a common theme among posts from 2020 (but not common in the 2021 and 2022 campaign posts) was the impact of the COVID-19 pandemic on GBV in Mexico. Posts in this theme highlighted the importance of the resources for GBV victims during this time and shared data or examples of how the pandemic increased GBV during the lockdown period in Mexico. Posts also cautioned that inaction could lead to setbacks in progress made toward gender equity. Table 6 presents selected quotations representing this theme.

Table 6. Representative quotes from theme 5 (the impact of the COVID-19 pandemic on gender-based violence).

Examples (posts translated into English)	Examples (posts in original language)
"We have stayed at home to avoid risks of contagion by #COVID19 but what happens if the risk is at home? Violence against women in the home has increased during the pandemic, but we can all help victims. #DíaNaranja #16Días #Únete" [2020 campaign]	"Nos hemos quedado en casa para evitar riesgos de contagio por #COVID19 pero ¿qué pasa si el riesgo está en casa? La violencia contra las mujeres en el hogar ha aumentado durante la pandemia, pero toda/os podemos ayudar a las víctimas. #DíaNaranja #16Días #Únete" [Campaña 2020]
"Shelters Helplines Advice Services for survivors are essential. Any type of support for victims of violence must be available to anyone who needs it, even during the #COVID19 pandemic. #DíaNaranja #16Días #Únete" [2020 campaign]	"Refugios Líneas telefónicas de ayuda Asesoramiento Los servicios para las sobrevivientes son esenciales. Cualquier tipo de apoyo a las víctimas de violencia debe estar disponible para quien lo necesite, incluso durante la pandemia de #COVID19. #DíaNaranja #16Días #Únete" [Campaña 2020]
"The pandemic is being particularly painful for women. If no action is taken, the progress in gender equality made over the last 25 years will be lost. #16Días #DíaNaranja #Únete" [2020 campaign]	"La pandemia está siendo particularmente dolorosa para las mujeres. Si no se adoptan medidas, los avances en la igualdad de género logrados en los últimos 25 años se perderán. #16Días #DíaNaranja #Únete" [Campaña 2020]

Discussion

Principal Findings

Using data from 3 years of social media activism by Mexican NGOs on X, we found that messaging surrounding the 16 Days of Activism Against GBV centered on the following: (1) activism and how to be an activist, (2) types of GBV, (3) changing the public discourse surrounding GBV, (4) GBV as a human rights violation, and (5) the impact of the COVID-19 pandemic on GBV. The posts from this campaign that were highly liked by the public reflect some of the biggest societal issues currently present in Mexico. In total, 3 of the 5 main themes identified—the types of GBV, activism and how to be an activist, and changing public discourse surrounding GBV—were present across the 3 campaign years. The impact of the COVID-19 pandemic on GBV and GBV as a violation of human rights were the more prevalent themes in 2020 and 2021 and 2022, respectively. Subsequent research on future campaigns could help better understand how these themes evolve in Mexican society over time.

Activism and how to be an activist was the most common theme among the posts analyzed during the 16 Days of Activism against GBV campaigns from 2020 to 2022. The activism in this annual campaign educates the public on GBV through posts that show the information in different ways, such as videos, songs, data, infographics, and citing influential people, to name a few. Similar to what other studies have found related to digital activism, the posts from this campaign provide information that makes the problem of GBV visible, which helps destigmatize GBV in Mexico [61,62]. A mixed methods study published in 2018 analyzed whether GBV activism through Facebook creates sisterhood among followers and found that the sisterhood created

XSL•FO
RenderX

on Facebook through the interaction and creation of groups and communities was translated into activism online and offline; this study noted that the lack of groups and communities on X does not allow this sisterhood to be created among X users [28]. However, we suggest that further analysis on X is needed to understand the potential of activism developing a sisterhood on this social media platform through reposts, replies, and other communication tools present on this platform.

Related to the different forms of GBV, sexual violence was the main form of violence highlighted in the analyzed posts. This resonates with the prevalence of sexual violence among the Mexican population, as this type of violence is the second most common form of GBV in Mexico [3]. Sexual violence prevalence among women aged ≥15 years increased from 41.3% in 2016 to 49.7% in 2021 [3]. Digital violence was another form of violence featured in the campaign posts. Digital violence soared in 2020 as a consequence of the COVID-19 pandemic [63]. This type of violence has continued to increase after the pandemic and affects girls and adolescent girls more than their male counterparts. Between 2021 and 2022, more than 33% of girls and adolescent girls in Mexico with access to a phone or internet experienced some form of digital violence, compared to 12% to 18% of Mexican boys and male adolescents [64]. As both forms of GBV continue to increase, the 16 Days of Activism against GBV campaign as well as other NGO- and non–NGO-based campaigns and prevention and intervention strategies should focus on sexual and digital violence in girls, adolescents, and women in Mexico.

We found that less commonly discussed forms of violence, such as economic violence, vicarious violence, lack of access to sexual and reproductive resources, and obstetric violence [65-69] were covered in the posts for these campaigns. Although other more commonly known forms of violence, such as sexual violence and intimate partner violence, were more commonly highlighted in these posts, having information on less commonly discussed forms of GBV within the campaign educated the public and provided tools to identify more types of violence. Indeed, although these forms of GBV are less commonly known by the public, it does not necessarily mean that these forms of violence are less prevalent. For example, Mexican national data have found that economic violence, which is not a well-known form of GBV in the country compared to physical, psychological, and sexual violence, is the most common form of GBV in the workplace [70].

A notable finding from theme 3, changing the narrative surrounding GBV, is that those called upon for change were not only individuals and the general public but also those in the public sector, including people in government leadership positions and health care providers. For the latter, the highly liked posts from the 3 campaign years acknowledged health care professionals as pillars of society for eradicating GBV in Mexico, one of the few countries with laws for the health care sector to address GBV at different prevention levels [71]. However, limited research has examined whether the Mexican health care sector is addressing GBV with their patients or working in other ways toward prevention. For example, a study completed among health care professionals in the states of Quintana Roo, Coahuila, and Mexico City found that while health care professionals were willing to address the issue of domestic violence with their patients, the care and attention needed for this specific type of violence was insufficient [72]. The awareness provided by the NGOs' posts and the engagement of the public on the vital role of these medical professionals in preventing and eliminating GBV could lead to the health care sector and other types of leadership organizations finally taking ownership of their role in reducing GBV.

A current social issue represented as a subtheme under theme 4, GBV as a human rights violation, was the violence experienced by vulnerable groups in Mexico, including migrant girls, adolescents, and women. Since 2018, caravans of migrants from Central and South America have traveled to Mexico in order to reach the United States, with girls, adolescents, and women being particularly vulnerable to different forms of GBV through their travels in Mexico [73,74]. According to the literature, migrants are more likely to be the victims of human trafficking [73], another form of GBV also present in highly liked posts for the 3 campaign years. However, the posts analyzed did not provide resources that could help prevent human trafficking, as these posts only had data on the prevalence of this GBV. Specific resources, such as phone numbers, may be more instrumental, particularly in states such as Chiapas, where migrants tend to stay longer and where it has been shown that GBV is more prevalent for this group [73]. A vulnerable group not mentioned in the highly liked posts that were analyzed was of Indigenous girls, adolescents, and women, even though they have consistently experienced GBV, structural violence, and institutional violence [75,76]. It is unknown if posts with fewer likes and thus not included in these analyses specifically mentioned this vulnerable group in posts by NGOs during the 3 campaign years. Future research on this topic is suggested to not only better understand the public's interest or awareness but also to identify different vulnerable groups that are not represented or addressed in nation-based campaigns or are not receiving broader support through recognition (likes).

Our results found that most of the messages on these posts exclusively mentioned women and younger girls, while only a few included adolescents. However, in Mexico, 60% of the adolescents aged between 15 and 17 years have experienced some type of GBV, and 40% have experienced sexual violence, while 80% of the minors aged <18 years who have disappeared in this country were adolescent girls aged between 12 and 17 years [4,77]. In addition, different studies have found a high prevalence of GBV in Mexican adolescent girls. For example, a study in the northern city of Tijuana found that most adolescent girls have experienced some form of intimate partner violence, more specifically, emotional, sexual, or physical abuse [78]. It is imperative for Mexico-based NGOs involved in future campaigns for 16 Days of Activism against GBV to be more inclusive of adolescent girls in their posts and have specific messages toward this age group, as they are vulnerable and in need of information to combat GBV, and to take account of the influence of social media toward adolescents. It is also important to state that the messages from most highly liked posts followed a collective voice, as these were written from a collective point of view in order to express ideas about GBV and activism against GBV through group unity, shared responsibility, and

XSL•FO
RenderX

changes as a group. This characteristic of the highly liked posts from Mexican NGOs is in line with existing literature, which has previously identified that Latin American feminist movements are distinguished by a collective voice compared to non-Latin American campaigns that have been framed through an individualized lens, such as the #MeToo movement [79].

Research using social media data to learn more about hashtag activism and hashtag feminism has grown in the last decade. Particularly, published literature on X data to analyze activism against GBV in the world has focused on hashtags in English [38,80], and most of it has been related to sexual violence [22,39,40,81]. Previous examples of hashtag feminism in Mexico include the #MeToo movement in 2017; #SiMeMatan (#IfTheyKillMe), used by women in response to the media and authority's secondary victimization of femicide victims; and #MiPrimerAcoso (#MyFirstAssault) in 2016, related to childhood sexual abuse, to name a few [82]. Some of these hashtags have been previously analyzed; however, to the best of our knowledge, we believe this research is one of the first studies to focus on Mexico-based NGOs, different campaign years, and more than 1 hashtag. This study provides important information on the types of messages that Mexico-based NGOs focused on in the prevention and elimination of GBV as well as what types of messages are potentially of more interest to the public. Future studies could further expand the limited knowledge on hashtag feminism against GBV in Mexico. For example, analyzing the demographics of the X users who liked these posts would provide context for understanding the population that follows this campaign. Analyzing other campaigns on GBV as well as the messages published and liked on other popular social media platforms in Mexico, such as Facebook, TikTok, and Instagram, is worth pursuing in future studies to further explore and better understand topics related to the prevention and elimination of GBV. Moreover, future research that quantifies post volume and interactive users through in-depth social network and semantic network analysis could provide more information on our findings by further exploring the level of user engagement and the evolution of discussions on GBV and activism over time. This tone of voice emerged across the 5 themes.

Finally, due to the inductive nature of this research, our study did not follow a theoretical framework. Nonetheless, our results lay the groundwork for future research that could benefit from the use of theoretical frameworks, such as the intersectionality framework [83], to further understand the intersecting identities of the public engaging in GBV campaigns and the feminist theory [84] to further study one of the main themes for this research, GBV as a violation of human rights, including gender inequities.

Strengths and Limitations

As noted earlier, to the best of our knowledge, this study is the first of its kind to conduct a comprehensive thematic content analysis using X data to examine GBV activism across Mexico at a national level. It delivers a groundbreaking perspective on the powerful impact of hashtag activism and feminist movements, offering an unprecedented understanding of social activism in the country. The research brings valuable insights into the topics related to GBV and the messages from this activist campaign that the public engages with the most. This high-level synthesis provides an overview of priorities and topics that can help NGOs and other types of organizations be more strategic in their social media campaigns and messages to combat GBV. For example, we note a gap in the provision of specific resources for those facing GBV; this may be a key area for future campaigns to build on. Despite these strengths, we recognize the inherent limitations in working with X data. First, the text content of posts is limited to up to 280 characters. This particular characteristic of X could hinder the amount of content that can be shared with the public. While some posts analyzed in this study included videos or infographics that could further expand the message shared by the NGO, most posts were messages of <280 characters with concise and specific yet limited information. First, we chose to use X data for analysis instead of another platform such as Facebook, as X offers a diverse dataset and has been one of the main channels used for hashtag feminism [39]. Second, while we collected and analyzed all the text present in the highly liked posts, we only analyzed the visual elements from the posts in the form of pictures and short videos (<1 min), losing the potential for more emerging themes to come from longer videos. Third, our study is limited to posts posted by NGOs that participated in the 16 Days of Activism against GBV campaigns. The results are not generalizable to other types of users (such as government agencies and celebrities) or to other hashtags related to the campaign that were not analyzed in this research. Fourth, this analysis was specific to NGOs based in Mexico and posts published in Spanish, so our results might not be generalizable to the campaign in other countries. Fifth, we focused our research on 4 hashtags (and their variations) specific to this campaign; therefore, it is possible that our research missed capturing other themes from other hashtags (such as #10D, #niunamenos [#notonemore], #niunaasesinadamás [#notonemoremurdered]) related to the 2020, 2021, and 2022 campaigns. Sixth, because of the limited number of posts (N=600) analyzed in this research, themes could have been missed; however, a sample size of 500 posts has been demonstrated to be sufficient to identify themes and understand the public's engagement [52,85]. Finally, the posts chosen for this analysis were based on the number of likes at the time of data collection. The number of likes on a post changes through time; therefore, the messages from these posts that generated the most attention and engagement from the public at the time of the campaign could have changed by the time the data were collected and might not reflect the engagement of the public with the different topics related to GBV. However, this is unlikely, as research has found that most likes on a post are given within 24 hours after the post is posted on X [86].

Conclusions

Our findings reveal that the highly liked posts for the 16 Days of Activism against GBV campaigns posted by Mexico-based NGOs in 2020, 2021, and 2022 are a reflection of the forms of violence and social issues that currently occur in the country. According to our results, informational posts about the types of GBV, the role of activism, and changing public discourse
